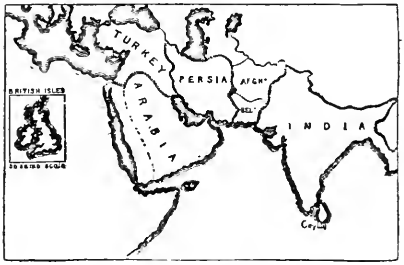
1839, remained a British possession. Thus Nejd itself, with the inland districts immediately adjoining, and the desolate coast districts of Mahrah and Hadramaut, are now the only parts of the peninsula where Arab independence can be said fully to maintain itself; though with this difference, that in the last-named provinces it is merely the independence of barbarism and poverty, while in the former it is that of organisation and not contemptible resources. Nor can it be well doubted that the recent encroachments of the Ottoman government, or rather misgovernment, will prove equally ephemeral with those of Sultan Selim or Mehemet Ali, and that Arabia will in a short time, probably within a few years, regain its previous autonomy Arab institutions are far from perfect, yet they are better than Ottoman oppression, and the Wahhabee empire might easily, under a judicious head, relax from its intolerance and become a centre, not of strength only, but of order, prosperity, and even civilisation, for the whole Arab nation, restoring, not, indeed, for external conquests, the days of which have long gone by, but for internal wellbeing, the better times of the Ommiade dynasty.

Future prospects.



Sketch, showing relative size of Arabia.

Antiquities.

Arabia proper is singularly destitute of antiquities, in the ordinary sense of the word, the northern or "Adscititious" Arabs having been, so long as they remained within their own territory, a remarkably unconstructive race, and the "pure" or southern Arabs not much better in this respect. Niebuhr, in his justly celebrated Travels through Yemen, mentions the ruins of Ghamdan, the ancient palace of the Himyarite kings, near Sanaá, as well as the remains of several other fortresses in adjoining villages; but these ruins, like those subsequently visited by Palgrave in Jowf, bore no distinctive traces of architecture or date, beyond a barbaric coarseness of material and great thickness of wall. More remarkable, because better defined in history, are the remains of the great dyke of Mareb already mentioned; its vestiges, said to be colossal in their dimensions, extend across a ravine of about 2 furlongs in breadth; they are in part of hewn stone, and testify, if not to the skill, at least to the diligence of the Himyarite Arabs. A few Himyaritic inscriptions have been discovered, some in Yemen, more in the provinces of Hadramaut and Mahrah, but have been too carelessly copied to afford proper materials for philological investigation. When decipherable, they indicate a dialect resembling the Abyssinian or Amharic; but throw no real light on the history of the country or the condition of its inhabitants.

Destruction of antiquities by the early Mahometans.

It is true that in addition to the non-constructive character of the early Arab race, account must be taken of the destructive policy, aggravated by iconoclastic zeal, pursued by the conquering Mahometan tribes of the north, who within their own territory, even more than in the acquired lands of Egypt, North Africa, and elsewhere, carried out the plan of establishing their own religion and system, not merely on the ruins, but, so far as possible, on the effacement of whatever had preceded it. Hence, of the old idol temples which once covered Arabia, nothing now remains except the megalithic vestiges of an enormous stone circle, resembling those found in some parts of Europe, and consisting of large boulders, each about 14 feet high, placed on end, and originally crowned by a similar horizontal series. This was visited by Palgrave when travelling in the province of Kaseem, near Bereydah; two others are reported to exist in the same district. Nor, the Meccan relics apart, had any of the numerous idols once worshipped throughout the peninsula been discovered till the Swiss Munzinger, three years since, found among the heaps of a deserted village near Aden a small bronze statue representing a naked hermaphrodite figure, over the head of which rises an ornament resembling the Egyptian *pshent*.

The black stone and Káabeh.

The black stone of the Meccan Káabeh, said to be of volcanic formation, and perhaps an aerolite, had, however, been an object of popular adoration long before Mahomet preserved it from destruction by giving it a place in a new and more enduring superstition; and the Káabeh itself, though ruined and rebuilt again and again, the last time in 1627, till not a vestige probably of the original structure now remains, has yet, it appears, certainly preserved the outline, and, in all essential respects, the dimensions of the original pagan shrine. It is an oblong massive structure, almost a trapezium, though the sides and angles are slightly unequal; its length 18 paces, its breadth 14, and its height from 35 to 40 feet. There are no windows, and the only entrance door is placed 7 feet above the ground; the entire building is of large, irregular, and unpolished blocks of ordinary stone. Its ornamentation is wholly modern.

Wells.

Lastly, several wells, jotted with seeming capriciousness over the desert, are said to be, and probably are, of great antiquity; certainly they are works which much exceed the skill of the Arabs of our own day. One such, "Beer Shekeef" by name, in the north-west of the peninsula, presents a cylinder of about 5 feet in diameter at top, but gradually enlarging till it reaches the water at a depth of nearly 200 feet, and is lined with hewn stone throughout. The Arabs declare it to be a work of pre-Islamitic times. Less remarkable in its proportions, but not less ancient, is the holy well called of Zemzem, at Mecca. But this and the great mosque of that city, as also the famous mosque of Medinah, which encloses the tomb of the prophet, and other buildings of the same category, will find their proper place in other articles. So will also the celebrated excavations of Petra, which, besides their being beyond the limits of Arabia proper, are not in themselves Arab but Græco-Roman in their character. With regard to the numerous mosques and other buildings, some of great beauty, erected by Arab architects in conquered countries, as in Syria, Egypt, Africa, or Spain, they are in fact nothing more than adaptations of the various local styles, and often of the very materials that the conquerors found ready to their hand.

Literature Pre-Islamitic poetry

But if poor in architectural, Arabia is superabundantly rich in literary monuments. Passing over as of more than doubtful authenticity the verses ascribed to kings and heroes of Yemen, especially at dates of a thousand years or more before the Christian era, we find undeniable specimens, at least two full centuries before Mahomet, of poems which in vigour and polish yield to few ever composed in the Arab or in any other language. To give at length the names and stories of the authors, many of them men, and even women, no less distinguished in their day by the sword than by the pen, would be, in a brief review like this, merely to note a dry and unmeaning catalogue. Suffice it that, even at this early date, we find the metrical and rhythmical laws, simple yet susceptible of the highest art, which have ever since regulated Arab poetry, already laid down in their completeness, and exemplified, the former by a scansion of almost Horatian elegance and variety, the latter by a severe nicety that Pope himself might have admired, but could hardly have imitated. Divided into sixteen classes, each class including several variations, the metres are based, like the Greek and Roman, on long and short vowels, irrespective of accent, but admitting cæsura, elision, and every prosodiacal delicacy. Some are adapted to gay, some to serious topics: love, war, description, moral precepts, philosophical speculation, elegy, satire—all find here their appropriate expression. The rhyme, which often involves not one but two syllables, is in every piece determined by that of the opening line. Alternate rhymes, choruses, and accentuated instead of quantitative metre, did not appear till later, and were imitated from extra-Arab models.

Public recitations.

Yearly, at the festival of Okad, the best masters of the art used to meet for the purpose of reciting their compositions, and receiving the reward, not of applause only, but also of more tangible advantages. Eulogies of chiefs, rulers, and distinguished men, formed a considerable portion of the poetry of those days; and a single ode or "kaseedah," as it was called, has been known to be rewarded, according to the means or liberality of the person eulogised, with a hundred valuable camels, or several thousand gold pieces. Love and war had also their inevitable share in the domain of verse, and descriptions of manner and scenery occur, though rarely in comparison. Lastly, elegies—some of them very touching in their deep and tender melancholy—and didactic pieces, chiefly ethical, take rank among the most carefully finished productions of the early Arab muse. Meanwhile, the greater number of poets had each his special patron, whose generosity took charge of the remuneration that in our days is looked for from the press; while a greater degree of publicity was given to a few chosen works of genius by the custom of suspending in some place of common resort (the Káabeh, it is asserted) such pieces as in the yearly gatherings of Okad had obtained the highest palm of acknowledged excellence. Seven of these, known in Arab literature by the title of the *Múallakat* or "Suspended," as being emphatically the best of their kind, and all of them belonging to the 6th century, have become for succeeding ages the accepted and classical standards of Arab poetical composition.

Prose literature.

Written prose up to the date of Mahomet's appearance there was absolutely none; and spoken eloquence, though always highly esteemed and diligently cultivated among the Arabs, had never been embodied in the permanence of writing. The irregular, half-rhythmical, half-rhyming sentences of the Koran were the first attempt in the direction of prose, which afterwards came into general use, and was applied to history, biography, philosophical treatises, romance, and every other description of subject. But prose never emancipated itself wholly from its original trammels of a misapplied cadence, to which was also too often added a redundant phraseology, the latter partly due to Persian literary influence; this florid style being, however, with many authors varied by breaks, as it were, of writing as excessive in its plainness as the other in its ornamentation.

Poetry.

But if unsuccessful in prose, the Arabs were not so in poetry. This, even before the era of the prophet, had, as we have seen, attained no ordinary degree of excellence; and it reached its highest point during the following century, under the Ommiade dynasty, when Omar Ebn Rabeeyah, of the tribe of Koreysh; Jameel, of the Benoo Adhrah; Jareer and Farazdak, both of Tameem; and Noseyyeb, a negro by birth—the first and second masters of erotic, the third and fourth of satirical, and the fifth of descriptive poetry—with a cloud of lesser celebrities, lived and sang in the sunshine of the Damascene court. The 8th and 9th centuries, agitated by civil dissensions or oppressed by the tyranny of the Abbasides, were less favourable to the Muses, till the reaction of the Greek and Persian minds, with which the Arab spirit was now yearly brought into more intimate contact, gave rise to a new and brilliant school, less true to the simplicity of nature or the purity of Arab diction, but richer in imagery and deeper in philosophic thought, illustrating, too, the transition from the objective to the subjective which has accompanied and half veiled decline in the literature of every nation, turn after turn. Abu-Teman, of the tribe of Tai, known not as a poet only, but also as a critic and the compiler of the celebrated anthology, the *Hamasa*, the "Golden Treasury" of the Arabs, first came forward in this field. His successor, the well-known Mutenebhe, is still esteemed by many the greatest of Arab poets; in range of thought and polish of diction he certainly excels all besides. Later still, in the 11th century, appeared Toghrai, who in his *Lameyyah*, the title of his principal piece, entered the lists against Shanfarah, the most brilliant of pre-Islamitic poets, and, it seems, furnished our own Tennyson with the model of his "Locksley Hall;" while a little later, Ebn Faridh, in Egypt, composed the mystico-erotic volume that has never in its kind been surpassed, or even equalled, by the poets of any land.

Decline of literature.

With the decline of the Arab race, however, their muse drooped also, and for many centuries maintained but a languishing existence, which in our own time has been galvanised rather than invigorated into a kind of revival by the modern literary schools of Beyrout, Damascus, Baghdad, and the Hejaz. In Nejd, Yemen, and Oman, rough poems on the primitive Arab model, besides others modulated with alternate rhymes, and in which accent takes the place of prosody, a species commonly called "Nabtee" or Nabathean verse, are yet in vogue. The Hispano-Arab poets, mostly mere imitators, and in bad taste too, need not detain us here. Epic and dramatic poetry were never even attempted by the Arabs.

Romance.

Romance, analogous though not similar to the European novel, was always a favourite branch of Arab literature; and in the *Thousand and One Nights* it obtained a world-wide celebrity and success. The original of this entertaining work appears to have been composed in Baghdad about the 11th century; another less popular but very spirited version is probably of Tunisian authorship, and somewhat later in date. The stories of Antarah, of the Benoo Hilal, of Mohalhel, of Barakat, and countless others, belong to the same class of writings, though cast in more of a biographical form, not unlike that adopted by the great Defoe. Strictly objective in character, the Arab novel, though often a vivid portraiture of the outside of men and customs, has never portrayed, or attempted to portray, the inner workings of the human mind.

Biography

With memoirs, biographies, collections of anecdotes, and the like, Arab literature is stored in excess, the bulk of such works being, as might be supposed, of somewhat superficial interest; while not a few of them are, on the contrary, possessed of great merit and value. Thus the *Book of Songs*, or "Kitab el Aghanee," composed in the latter part of the 10th century by Abu-Faraj, of Ispahan, and containing, in twenty successive volumes, short but entertaining notices of all the principal Arab poets or singers, with specimens of their compositions, is, in addition to its speciality, a perfect treasure of the most varied information regarding the men and the times; and the *Life of Mahomet*, by Abul-Feda, of Aleppo, displays considerable critical acumen as well as narrative power. Nor should we forget the judiciously-selected biographies of Mahometan celebrities by Ebn Khallikan, in the 12th century, or those of Koteybah of an earlier date; but of such compositions as these the Arab name is legion.

History.

History, however, proved from first to last an effort beyond Arab skill, which contented itself with the less intellectual task of multiplying chronicles to an almost unparalleled amount. In this the voluminous work of Ebn

Atheer, which, after commencing the Arab annals, along with those of the world from the creation itself, carries them down to the overthrow of the Abbaside caliphate in the 13th century; that of Musa'oodee, containing a pre-Islamitic summary of the geography and history of the world in general, till the birth of Mahomet, after which the chronicle confines itself exclusively to the fortunes of the Arab empire; and that of Abul-Feda, especially interesting by its curious notices of pagan Arabia, may be mentioned as favourable specimens in their line. In particular, Egypt was amply chronicled by Makreezee and Siyootee; Spain by Makkaree; Africa by Ebn Kateeb; Syria and Baghdad by writers out of number. A more voluminous, and, it must be added, a more childish collection of writings could scarcely be found in any language.

Theological writings. We may imagine (for it would be a waste of time to catalogue) the theological writings, glossaries, commentaries, discourses, and so forth, which, from the first century of Mahometanism to the extinction of Arab empire, have illustrated or obscured the great book on which that empire was founded—the Koran. Beydawee in the 10th, Jelal-ed-deen and Bokharee in the 11th, and El Ghazalee in the 12th century of our era, each was in his day considered a master in Islam, and their treatises are still reverentially studied in its schools. Legal dissertations by Malek, Ebn Hanbal, Shafeyee, Hanefee, and their disciples, load the shelves of every Arab bookcase; but the authors themselves were mostly of extra-Arab origin, and often reflect the Persian, the Turkoman, and even the Byzantine, rather than the genuine Arab mind.

Astronomy. From the fancies of astrology, in which the early Arabs—not wiser than their neighbours, but favoured with clearer skies—seem to have indulged freely, and which, though discountenanced by the practical good sense of Mahomet himself, have never been wholly abandoned by their descendants, a not unnatural transition led to the more useful study of astronomy. Specially patronised by the Abbaside caliph Al-Mamun, the Augustus of his race (813–833 A.D.), this science made great and rapid progress. The obliquity of the ecliptic, the diameter of the earth, and even the precession of the equinoxes, were then calculated with commendable accuracy; and shortly after, Abul-Mezar's *Introduction to Astronomy* and his *Treatise on the Conjunction of the Planets*, with the *Elements* of Al-Furjanee (though this last author was largely indebted to the Egyptian labours of Ptolemy), proved that the caliph's liberality had been well bestowed. But Al-Batinee, a native of Syria (879–920 A.D.), surpassed all his predecessors in the nicety alike of his observations and computations. Geber, at Seville, constructed (1196 A.D.) the first astronomical observatory on record; and Ebn-Korrah in Egypt proved by his example that the Arabs could be even better astronomers than the Greeks had been before them. Yet although the doctrine of attraction seems to have been dimly surmised by some of them, none ever succeeded in emancipating themselves from the clumsy and erroneous Ptolemaic geocentric system.

Mathematics. In mathematics the Arabs based themselves on what they had acquired from the Greek and Indian originals; the former gave them geometry, the latter algebra. Satisfied at first with translations of Euclid, Apollonius, and others, they ultimately left their masters behind. They reached in the 10th century the limits of spherical trigonometry, and solved quadratic and even cubic equations. In these studies the astronomers Geber and Ebn-Moosa chiefly distinguished themselves. Optics, too, and hydrostatics were investigated by the professors of Baghdad; but no special progress or remarkable discoveries are recorded as having been made in these sciences. In mixed as well as in pure mathematics the leading-strings of the Greek became the fetters of the Arab mind. Their practical application, however, of hydraulics in the construction of wells, water-works, reservoirs, sluices, canals, and the like, does them great credit; and of this peculiar skill ample traces, ill maintained by succeeding governments, remain in Spain, North Africa, Egypt, Syria, and Mesopotamia.

Fine arts. Debarred by religious scruples from the representation of animated forms in sculpture or painting, Arab decorators (for they are no more) found themselves restricted to vegetable or fantastic patterns and colour combinations, and in these, as the Spanish Alhambra and other buildings can testify, showed themselves no mean proficients. They made great use of glazed tiles and stucco, and possessed the art—one that they have lost long ago—of staining glass. Lastly, music, as the handmaid and enhancer of poetry, was a favourite and honoured pursuit among the Arabs, who, with comparatively rough instruments,—the rudiments of the flute, harp, tabor, and guitar, rather than the instruments themselves,—and with a scale, carefully and scientifically elaborated, but essentially differing from our own, produced results that real excellence alone could have merited or obtained. The voluminous "Book of Songs" already alluded to contained the history and points out the distinctive characteristics of a hundred airs, each esteemed a masterpiece by competent judges. For one alone its composer received from the Caliph Al-Nathik-Billah (842 A.D.) a sum equivalent to nearly £2300 sterling. It is noticeable that though the best voices were furnished by the Hejaz, the instrumental and scientific part was perfected by Persian instruction under the Abbaside caliphs of Baghdad.

Music.

Medicine and surgery. More widely recognised, however, are the Arab claims to proficiency in medicine, an art which Mahomet himself appears to have dabbled in, showing himself, if tradition speaks true, by no means so good a physician as he was a preacher. Under the caliphs, however, regular schools of the therapeutic science were established in Damascus, Baghdad, and Cairo, where the works of Hippocrates and Galen, translated from their originals in Greek, were adopted as the basis of instruction. Hence the great medical treatise entitled *El-Melekei*, or "The Royal," of Ali-Ebn-Abbas, which appeared in Aleppo towards the end of the tenth century, was essentially an enlargement of and appendix to the Galenic teaching. Shortly after Er-Razi, the Baghdad professor, published his writings on pathology, containing the first authentic description of exanthematous diseases. The *Canon* of Ebn Sina, commonly known as Avicenna, born 980 A.D., with his *Materia Medica*, which preluded in some respects that of Paracelsus, ultimately, however, superseded every other work in the Arab schools. But the neglect of anatomical study, with a superstitious horror of the practice of dissection, rendered the surgery of the Arabs imperfect and their medicine empirical. The invention of the probang and some improvements in the lancet and the couching needle are due, nevertheless, to Arab surgeons.

Botany and chemistry. Botany was chiefly studied as subsidiary to medicine; nor did chemistry ever attain the dignity of a separate science; as, however, an adjunct to the old herbal pharmacopœia, it received close and not unsuccessful attention. The principal mercurial and arsenical preparations of the *materia medica*, the sulphates of several metals, the properties of acids and alkalies, the distillation of alcohol,—in fine, whatever resources chemistry availed itself of up to a very recent date—were, with their practical application, known to Er-Razi and Geber, already mentioned. In fact, the numerous terms borrowed from the Arabic language—alcohol, for instance, alkali, alembic, and others—with the signs of drugs and the like, still in use among modern apothecaries, have remained to show how deeply this science is indebted to Arab research.

Grammar and rhetoric. Finally, and as though to counteract any foreign influence that the cultivation of these exotic sciences might correlatively introduce, Arab grammar and rhetoric were, from the days of the first Ommiade to those of the last Abbaside caliph, considered an indispensable item of respectable education. Every nicety of the language was investigated in the 8th, 9th, and 10th centuries by the rival schools of Cufa and Bosrah; and the *Alfeeyah*, a grammatical treatise of the celebrated Ebn-Malek, a native of the latter city, who flourished in the 9th century, is even now the standard work in the hand of every professor. But for absolute mastership, joined with exquisite taste, in the use of the subtlest refinements both of rhetoric and grammar, the palm must be assigned to Hareeree, the author of the celebrated *Makamat* or *Sessions*, a work esteemed by many as hardly less wonderful in the talent it displays than the Koran itself. It belongs to the 11th century, and though it has had many imitators, has never yet acknowledged a rival.

Mechanical inventions. Industrious and enterprising, the Arabs led the way by their invention and skill to most of the more complicated manufactures of our own times. In metallurgy, their art in tempering and enamelling has become justly famous; nor did any sword-blades ever rank higher than those of Damascus, nor any coppersmiths excel those of Baghdad, or gold and silver workmanship that of Oman. Specimens of their skill in porcelain yet remain in Spain and Syria; while the popular words "morocco" and "cordovan" attest their cleverness in preparing and dyeing leather. The pendulum and the semaphoric telegraph, if not invented, as some think, by the Arabs, were certainly introduced by them into Europe, as was also the manufacture of silk and of cotton, and an invention of the highest value—the mariner's compass. As early as 706 A.D. writing-paper was made at Mecca, whence it spread through all the Arabian dominions, and ultimately reached the Western world. In the discovery or use of gunpowder, so far back as the 11th century, the Arab claim to priority is contested by the Byzantines alone.

Influence of the Arab mind. In a word, the literature, arts, and sciences of the Arabs formed the connecting link between the civilisations of ancient and modern times; and the culture which they introduced into the countries they conquered has in almost every instance outlasted the rule of the conquerors themselves. To them, directly and indirectly, we owe the revival of learning and philosophy in Western Europe, and the first awakening of the critical and inquiring spirit that has in great measure rescued Europe from the lethargy of monkish ignorance and ecclesiastical bigotry; to them also, at least indirectly and by deduction, are due most of the useful arts and practical inventions laboriously perfected by later nations. Wide-spread as was the empire of the Arab sword, it has been less extended and less durable than the empire of the Arab mind. (W. G. P.)

ARABIAN PHILOSOPHY owed to Arabia little more than its name and its language. It was a system of Greek thought, expressed in a Semitic tongue, and modified by Oriental influences, called into existence amongst the Moslem people by the patronage of their more liberal princes, and kept alive by the intrepidity and zeal of a small band of thinkers, who stood suspected and disliked in the eyes of their nation. The Arabian philosophers have but a secondary interest in the history of their own lands. Their chief claim to the notice of the historian of speculation comes from their warm reception of Greek philosophy when it had been banished from its original soil, and whilst Western Europe was still too rude and ignorant to be its home. In the annals of philosophy the period from the beginning of the 9th to the close of the 12th century may be styled the "Flight into Egypt." During these four centuries free thought found a refuge under Mahometan princes until her oppressors were dead. In the course of that exile the traces of Semitic or Mahometan influence gradually faded away; and the last of the line of Saracenic thinkers was a truer exponent of the one philosophy which they all professed to teach than the first. The whole movement was little else than a chapter in the history of Aristotelianism. That system of thought, after passing through the minds of those who saw it in the hazy light of an Orientalised Platonism, and finding many laborious but narrow-purposed cultivators in the monastic schools of heretical Syria, was then brought into contact with the ideas and mental habits of Islam. But those in whom the two currents converged did not belong to the pure Arab race. Of the so-called Arabian philosophers of the East, Al-Farabi, Ibn-Sina, and Al-Ghazâli were natives of Khorassan, Bokhara, and the outlying provinces of north-eastern Persia; whilst Al-Kendi, the earliest of them, sprang from Basra, on the Persian Gulf, on the debatable ground between the Semite and the Aryan. In Spain, again, where Ibn-Badja, Ibn-Tofail, and Ibn-Roshd rivalled or exceeded the fame of the Eastern schools, the Arabians of pure blood were few, and the Moorish ruling class was deeply intersected by Jewish colonies, and even by the natives of Christian Spain. Thus, alike at Baghdad and at Cordova, Arabian philosophy represents the for a time victorious reaction of exotic ideas and of subject races against the theological one-sidedness of Islam, and the illiterate simplicity of the early Saracens.

Islam had, it is true, a philosophy of its own. There were Schoolmen amongst the believers in the Koran, not less than amongst the Latin Christians. At the very moment when Mahometanism came into contact with the older civilisations of Persia, Babylonia, and Syria, the intellectual habits of the new converts created difficulties with regard to its very basis, and showed themselves a prolific source of diversity in the details of interpretation. The radical questions on which these disputes turned were two. The first dealt with the possibility of ascribing manifold attributes to God—to a Being who was absolute unity. The other referred to the bearing of God's omnipotence upon the freedom of the human will. Ere the second century of the Hegira, sturdy adherents of the literal truth of the Koran taught a gross anthropomorphism, applying to the Creator the very bodily attributes of his creatures. These were the Sefatites, or partisans of the attributes. Another sect represented Mahomet as the teacher of an unqualified fatalism. Opposed to these narrow-minded exponents stood the comparatively liberal sect of the Motazalites, the Dissidents, who first appeared about 750. As they maintained, on one hand, that man was in some degree a free agent, and on another, elevated the unity of the divine nature far above the diversity of attributes, they came to be styled the partisans of justice and unity. It was with them that the Mussulman theology—the science of the word (*Calâm*)—first came into existence. Its professors, the *Motecallemîn* (known in Hebrew as *Medabberim*, and as *Loquentes* in the Latin versions) may be compared with the scholastic doctors of the Catholic Church. Driven in the first instance to speculation in theology by the needs of their natural reason, they came, in after days, when Greek philosophy had been naturalised in the Caliphate, to adapt its methods and doctrines to the support of their views. They employed a quasi-philosophical method, by which, according to Maimonides, they first reflected how things ought to be in order to support, or at least not contradict, their opinions, and then, when their minds were made up with regard to this imaginary system, declared that the world was no otherwise constituted. The dogmas of creation and providence, of divine omnipotence, chiefly exercised them; and they sought to assert for God an immediate action in the making and the keeping of the world. Space they looked upon as pervaded by atoms possessing no quality or extension, and time was similarly divided into innumerable instants. Each change in the constitution of the atoms is a direct act of the Almighty. When the fire burns, or the water moistens, these terms merely express the habitual connection which our senses perceive between one thing and another. It is not the man that throws a stone who is its real mover: the supreme agent has for the moment created motion. If a living being die, it is because God has created the attribute of death; and the body remains dead, only because that attribute is unceasingly created. Thus, on the one hand, the object called the cause is denied to have any efficient power to produce the so-called effect; and, on the other hand, the regularities or laws of nature are explained to be direct interferences by the Deity. God is the sole cause or agent in the universe: it is He who, directly, or by the mediation of His ministering angels, brings everything to pass. The supposed uniformity and necessity of causation is only an effect of custom, and may be at any moment rescinded. In this way, by a theory which, according to Averroes, involves the negation of science, the Moslem theologians believed that they had exalted God beyond the limits of the metaphysical and scientific conceptions of law, form, and matter; whilst they at the same time stood aloof from the vulgar doctrines, attributing a causality to things. Making the uniformity of nature a mere phantom due to our human customary experience, they deemed they had left a clear ground for the possibility of miracles.

But at least one point was common to the theological and the philosophical doctrine. Carrying out, it may be, the principles of the Neo-Platonists, they kept the sanctuary of the Deity securely guarded, and interposed between him and his creatures a spiritual order of potent principles, from the Intelligence, which is the first-born image of the great unity, to the Soul and Nature, which come later in the spiritual rank. Of God the philosophers said we could not tell what He is, but only what He is not. The highest point, beyond which strictly philosophical inquirers did not penetrate, was the active intellect,—a sort of soul of the world in Aristotelian garb—the principle which inspires and regulates the development of humanity, and in which lies the goal of perfection for the human spirit. In theological language the active intellect is described as an angel. The inspirations which the prophet receives by angelic messengers are compared with the irradiation of intellectual light, which the philosopher wins by contemplation of truth and increasing purity of life. But while the theologian incessantly postulated the agency of that God, whose nature he deemed beyond the pale of science, the philosopher, following a purely human and natural aim, directed his efforts to the gradual elevation of his part of reason from its unformed state, and to its final union with the controlling intellect which moves and draws to itself the spirits of those who prepare themselves for its influences. The philosophers in their way, like the mystics of Persia (the Sufites) in another, tended towards a theory of the communion of man with the spiritual world, which may be considered a protest against the practical and almost prosaic definiteness of the creed of Mahomet.

Arabian philosophy, at the outset of its career in the 9th century, was able without difficulty to take possession of those resources for speculative thought, which the Latins had barely achieved at the close of the 12th century by the slow process of rediscovering the Aristotelian logic from the commentaries and versions of Boëthius. What the Latins painfully accomplished, amid many senseless disputations and blind gropings after light, owing to their fragmentary and unintelligent acquaintance with ancient philosophy, was already done for the Arabians by the scholars of Syria. In the early centuries of the Christian era, both within and without the ranks of the church, the Platonic tone and method were paramount throughout the East. Their influence was felt in the creeds which formulated the orthodox dogmas in regard to the Trinity and the Incarnation. But in its later days the Neo-Platonist school came more and more to find in Aristotle the best exponent and interpreter of the philosopher whom they thought divine. It was in this spirit that Porphyry, Themistius, and Joannes Philoponus composed their commentaries on the treatises of the Peripatetic system which, modified often unconsciously by the dominant ideas of its expositors, became in the 6th and 7th centuries the philosophy of the Eastern Church. But the instrument which, in the hands of John of Damascus, was made subservient to theological interests, became in the hands of others a dissolvent of the doctrines which had been reduced to shape under the prevalence of the elder Platonism. Peripatetic studies became the source of heresies; and conversely, the heretical sects prosecuted the study of Aristotle with peculiar zeal. The church of the Nestorians, and that of the Monophysites, in their several schools and monasteries, carried on from the 5th to the 8th century the study of the earlier part of the Organon, with almost the same means, purposes, and results as were found among the Latin schoolmen of the earlier centuries. Up to the time when the religious zeal of the Emperor Zeno put a stop to the Nestorian school at Edessa, this "Athens of Syria" was active in translating and popularising the Aristotelian logic. Their banishment from Edessa in 489 drove the Nestorian scholars to Persia, where the Sassanidae gave them a welcome; and there they continued their labours on the *Organon*. A new seminary of logic and theology sprung up at Nisibis, not far from the old locality; and at Gandisapora (or Nisabur) in the east of Persia, there arose a medical school, whence Greek medicine, and in its company Greek science and philosophy, ere long spread over the lands of Iran. Meanwhile the Monophysites had followed in the steps of the Nestorians, multiplying Syriac versions of the logical and medical science of the Greeks. Their school at Resaina is known from the name of Sergius, one of the first of these translators, in the days of Justinian; and from their monasteries at Kinnesrin (Chalcis) issued numerous versions of the introductory treatises of the Aristotelian logic. To the *Isagoge* of Porphyry, the *Categories* and the *Hermeneutica* of Aristotle, the labours of these Syrian schoolmen were confined: these they expounded, translated, epitomised, and made the basis of their compilations; and the few who were bold enough to attempt the *Analytics*, seem to have laid down the pen with their task unaccomplished.

The energy of the Monophysites, however, began to sink with the rise of the Moslem empire; and when philosophy revived amongst them in the 13th century, in the person of Gregorius Barhebræus (1226–1286), the revival was due to the example and influence of the Arabian thinkers. It was otherwise with the Nestorians. Gaining by means of their professional skill as physicians a high rank in the society of the Moslem world, the Nestorian scholars soon made Baghdad familiar with the knowledge of Greek philosophy and science which they possessed. But the narrow limits of the Syrian studies, which added to a scanty knowledge of Aristotle some acquaintance with his Syrian commentators, were soon passed by the curiosity and zeal of the students in the Caliphate. During the 8th and 9th centuries, rough but generally faithful versions of Aristotle's principal works were made into Syriac, and then from the Syriac into Arabic. The names of some of these translators, such as Johannitius (Honein ibn-Ishak), were heard even in the Latin schools. By the labours of Honein and his family the great body of Greek science, medical, astronomical, and mathematical, became accessible to the Arab-speaking races. But for the next three centuries fresh versions, both of the philosopher and of his commentators, continued to succeed each other.

To the Arabians Aristotle represented and summed up Greek philosophy, even as Galen became to them the code of Greek medicine. They adopted the doctrine and system which the progress of human affairs had made the intellectual aliment of their Syrian guides. It was a matter of historical necessity, and not an act of deliberate choice. Just as the early poets of Rome, when they tried to naturalise the drama, reproduced the works of Euripides, the popular tragedian of their time, so the Arabians, when the need of scientific culture awoke amongst them, accepted Aristotle. From first to last Arabian philosophers made no claim to originality; their aim was merely to propagate the truth of Peripateticism as it had been delivered to them. In medicine and astronomy, as well as in philosophy, they entertained an almost superstitious reverence for their Greek teachers. It was with them that the deification of Aristotle began, and from them the belief that in him human intelligence had reached its limit passed to the later schoolmen. The doctrine is fixed truth has been ascertained: all that is needed is a faithful and skilful interpreter. Hence, their perpetual labour of exposition and illustration: their epitomes and paraphrases of Aristotelian doctrine. The progress amongst the Arabians on this side lies in a closer adherence to their text, a nearer approach to the bare exegesis of their author, and an increasing emancipation from control by the tenets of the popular religion.

Secular philosophy found its first entrance amongst the Saracens in the days of the early caliphs of the Abbaside dynasty, whose ways and thoughts had been moulded by their residence in Persia amid the influences of an older creed, and of ideas which had in the last resort sprung from the Greeks. The seat of empire had been transferred to Baghdad, on the highway of Oriental commerce, and the distant Khorassan became the favourite province of the caliph. Then was inaugurated the period of Persian supremacy, during which Islam was laid open to the full current of alien ideas and culture. The incitement came, however, not from the people, but from the prince: it was in the light of court favour that the colleges of Baghdad and Nisabur first came to attract students from every quarter, from the valleys of Andalusia, as well as the upland plains of Transoxiana. Al-Mansûr, the second of the Abbasides, encouraged the appropriation of Greek science, but it was Al-Mamûn, the son of Harûn al-Rashid, who deserves in the Mahometan empire the same position of royal founder and benefactor which is held by Charlemagne in the history of the Latin schools. In his reign (813–833) Aristotle was first translated into Arabic. Legend told how Al-Mamûn had been induced to send to the Byzantine emperor for Greek books on philosophy, in consequence of a vision in which a venerable personage, who made himself known as Aristotle, had excited without gratifying the curiosity of the caliph. Orthodox Mussulmans, however, distrusted the course on which their chief had entered, and his philosophical proclivities became one ground for doubting as to his final salvation.

In the Eastern provinces the chief names of Arabian philosophy are those known to the Latin schoolmen as Alkindius, Alpharabius, Avicenna, and Algazel, or under forms resembling these, or under other names derived from various parts of their complex Arabic designations. The first of these, Alkindius (Abu Jusuf Jacub ibn-Ishak *al-Kendi*), wrote in the reigns of Al-Mamûn and Al-Motassem (813–842). His claims to notice at the present day rest upon a few works on medicine and the astrological astronomy of his age,—the only remnant left of the 200 treatises which he is said to have composed on all the themes of science and philosophy. With him begins that encyclopædic character—the simultaneous cultivation of the whole field of investigation which is reflected from Aristotle on the Arabian school. Towards the close of the 10th century the presentation of an entire scheme of knowledge, beginning with logic and mathematics, and ascending through the various departments of physical inquiry to the region of religious doctrine, was accomplished by a society which had its chief seat at Basra, the native town of Al-Kendi. This society—the Brothers of Purity or Sincerity—divided into four orders, wrought in the interests of religion no less than of science; and though its attempt to compile an encyclopædia of existing knowledge may have been premature, it yet contributed to spread abroad a desire for further information. The proposed reconciliation between science and faith was not accomplished, because the compromise could please neither party. The fifty-one treatises of which this encyclopædia consists are interspersed with apologues in true Oriental style, and the idea of goodness, of moral perfection, is as prominent an end in every discourse as it was in the alleged dream of Al-Mamûn. The materials of the work come chiefly from Aristotle; but they are conceived in a Platonising spirit, which places as the bond of all things a universal soul of the world with its partial or fragmentary souls. Contemporary with this semi-religious and semi-philosophical society lived Alfarabius (Abou-Nasr Mohammed ben-Mohammed ben-Tarkhan *al-Farabi*) or Abunasar. From Turkestan, the place of his birth, he passed southward to Baghdad where he studied, and died at Damascus in 950, after living for some time at Aleppo on the invitation of its prince. The legendary accounts of Al-Farabi describe him as a man of vast erudition, the master of seventy languages, and accomplished both in the theory and the practice of the musical art. Of his numerous writings on all the branches of science only a few remain in Arabic or Hebrew versions, but his paraphrases of Aristotle formed the basis on which Avicenna constructed his system, and his logical treatises produced a permanent effect on the logic of the Latin scholars. He gave the tone and direction to nearly all subsequent speculations among the Arabians. His order and enumeration of the principles of being, his doctrine of the double aspect of intellect, and of the perfect beatitude which consists in the aggregation of noble minds when they are delivered from the separating barriers of individual bodies, present at least in germ the characteristic theory of Averroes. But Al-Farabi was not always consistent in his views; a certain sobriety checked his speculative flights, and although holding that the true perfection of man is reached in this life by the elevation of the intellectual nature, he came towards the close to think the separate existence of intellect no better than a phantasm and delusion.

Unquestionably the most illustrious name amongst the Oriental Moslems was Avicenna (980–1037). His fame in Europe rested more upon his medical canon than on his philosophical works; but even in logic and metaphysics his influence on the West was considerable. With him the encyclopædic tendencies of the school of Baghdad reached their culmination. He was followed by Algazel (Abou

Hamed Mohammed ibn-Mohammed al-Ghazâli), whose name was the last that attained a European reputation. Born near Tûs in 1058, he studied there and at Nisabur; and having left his native province of Khorassan at the age of 36, he was appointed to a high educational post at Baghdad. There, as well as at Damascus, Jerusalem, and Alexandria, his lectures attracted crowds of eager listeners. Suddenly he withdrew from active life, assumed the habits of the Sufite mystic, and devoted himself to contemplation of religious truth; and although he was persuaded to resume for a while his duties in the college of Baghdad, he soon returned to seclusion, and passed his last days in a monastery which he had himself founded at Tûs (1111). To Algazel it seemed that the study of secular philosophy had resulted in a general indifference to religion, and that the scepticism which concealed itself under a pretence of piety was destroying the life and purity of the nation. With these views he carried into the fields of philosophy the aims and spirit of the Moslem theologian. In his *Tendencies of the Philosophers* (*Makâcid al-Falâsifa*) he gave a resumé of the contemporary state of the speculative sciences as a preliminary work to his *Destruction of the Philosophers* (*Tehâfot al-Falâsifa*), in which the contradictions and errors of these sciences were pointed out, as well as their divergence from the orthodox faith. This indictment against liberal thought from the stand-point of the theological school was afterwards answered in Spain by Averroes; but in Baghdad it heralded the extinction of the light of philosophy. Moderate and compliant with the popular religion as Alfarabius and Avicenna had always been, as compared with their Spanish successor, they had equally failed to conciliate the popular spirit, and were classed in the same category with the heretic or the member of an immoral sect. The 12th century exhibits the decay of liberal intellectual activity in the Caliphate, and the gradual ascendency of Turkish races animated with all the intolerance of semi-barbarian proselytes to the Mahometan faith. Philosophy, which had only sprung up when the purely Arabian influences ceased to predominate, came to an end when the sceptre of the Moslem world passed away from the dynasty of Persia. Even in 1150 Baghdad had seen a library of philosophical books burned by command of the Caliph Mostandjed; and in 1192 the same place might have witnessed a strange scene, in which the books of a physician were first publicly cursed, and then committed to the flames, while their owner was incarcerated. Thus, while the Latin church showed a marvellous receptivity for ethnic philosophy, and assimilated doctrines which it had at an earlier date declared impious, in Islam the theological system entrenched itself towards the end of the 12th century in the narrow orthodoxy of the Assarites, and reduced the votaries of Greek philosophy to silence.

The same phenomena were repeated in Spain under the Mahometan rulers of Andalusia and Marocco, with this difference, that the time of philosophical development was shorter, and the heights to which Spanish thinkers soared were greater. The reign of Al-Hakem the Second (961–976) inaugurated in Andalusia those scientific and philosophical studies which were simultaneously prosecuted by the Society of Basra. From Cairo, Baghdad, Damascus, and Alexandria, books both old and new were procured at any price for the library of the prince, 27 free schools were opened in Cordova for the education of the poor; and intelligent knowledge was perhaps more widely diffused in Mahometan Spain than in any other part of Europe at that day. The mosques of the city were filled with crowds who listened to lectures on science and literature, law and religion. But the future glory thus promised was long postponed. The usurping successor of Hakem found it a politic step to request the most notable doctors of the sacred law to examine the royal library; and every book treating of philosophy, astronomy, and other forbidden topics, was condemned to the flames. But the spirit of research, fostered by the fusion of races and the social and intellectual competition thus engendered, was not crushed by these proceedings; and for the next century and more the higher minds of Spain found in Damascus and Baghdad the intellectual aliment which they desired. At last, towards the close of the 11th century, the long-pent spiritual energies of Mahometan Spain burst forth in a brief series of illustrious men. Whilst the native Spaniards were narrowing the limits of the Moorish kingdoms, and whilst the generally fanatical dynasty of the Almohades might have been expected to repress speculation, the century preceding the close of Mahometan sway saw philosophy cultivated by Avempace, Abubacer, and Averroes. Even amongst the Almohades there were princes, such as Jusuf (who began his reign in 1163) and Jacûb Almansor (who succeeded in 1184), who welcomed the philosopher at their courts, and treated him as an intellectual compeer. But about 1195 the old distrust of philosophy revived; the philosophers were banished in disgrace; works on philosophical topics were ordered to be confiscated and burned; and the son of Almansor condemned a certain Ben-Habib to death for the crime of philosophising.

Arabian speculation in Spain was heralded by Avicebron, a name under which the schoolmen conceived an Arab thinker, whereas modern scholars have shown that he was identical with Salomon ben-Gebirol, a Jewish sacred poet of no mean order, and still popular in the synagogue. Born at Malaga, and educated at Saragossa, he seems to have written most of his works between 1045 and 1070. His philosophical essay, known as the *Fountain of Life* (*Fons Vitæ*), although, in a Latin version made about 1150, it acted like a ferment amongst the seething mass of heterodox Christian theology, found no immediate acceptance among his own philosophical compatriots, or amongst the Arabian thinkers who succeeded him. His speculations were drawn from sources other than those which supplied the dominant school of the 12th century in Spain, and found a congenial home amongst those who had drunk deeply from the ideas of Scotus Erigena. The doctrine of Avicebron attributed matter to everything, even to the soul, and to simple substances, and held that ultimately there was one universal matter. Thus, while intelligible and sensible substances differ in their forms, they are at one in matter. The doctrine became important in the disputes as to the principle of individuation; where Duns Scotus, in opposition to Aquinas, reverted to the position of Avicebron, whom he also resembled in his doctrine of the superiority of the will to the intellect.

Such questions in the present age would seem to fall strictly within the sphere of logic. But it was the characteristic of the thinkers of the mediæval period, both Arabian and Christian, to magnify the power of abstract ideas, and to give a deep reality to logical and metaphysical ideas. The earlier schoolmen exaggerated the value of genera and species, till everything else grew faint in comparison, and the Arabian thinkers similarly took in awful earnest the distinction of material and formal. Abstractions were first realised with uncommon distinctness and became almost palpable; and then they were introduced into the world of popular conception. An irresistible attraction drew thinkers of different classes to apply their metaphysical subtleties to the religious ideas of a celestial order of beings, and the results of this application not unnaturally gave rise to heresies.

The ideas of Avicebron are the one-sided consequences of principles which had an influence, but a secondary one, on the whole Arabian school. They descend in the last instance from the Alexandrians,—particularly as Alexandrian ideas are presented in the book *De Causis*, and in the *Apocryphal Theology* of Aristotle. Both of these works (which passed under a variety of other names) belong to a class of writings of Neo-Platonic tone and contents, which were accredited by their ascription to Pythagoras, Empedocles, Plato, and Aristotle, and circulated amongst the Arabians before the canon of Peripatetic scriptures had been definitively fixed by the school of Baghdad. The *Theology* known as Aristotle's did not appear in Latin before 1519, when it was translated from an Arabic manuscript of the 9th century, whereas the *De Causis*, although unknown to the Moslem world, was familiar to the Latins of the 13th century The *Theology* was an exposition of the theory of Plotinus, the *De Causis* was extracted from the *Theological Elements* of Proclus, and both works presented the usual Alexandrian system of emanation and hypostases,—the graduated series of externalisations and manifestations of the first cause or absolute unity, firstly, in Intelligence, secondly, in the Soul of the universe, thirdly, in Nature and the region of mutability. These sucessive spheres of being, where the central unity expands into the circumference without losing its simplicity, and the circumference is instinctively led towards its controlling centre, lay at the basis of the conception of the universe held more or less by all the Moslem philosophers. The first of creatures, says Avicenna, is the Intelligence, in which are contained soul and life. The first cause is above all intelligence. The principles exert a causal influence according to their degree of elevation.

About a generation after Avicebron the rank of Moslem thinkers proper was introduced by Abou-Bekr Mohammed ben-Jahya, surnamed Ibn-Badja, and known to the Latin world as Avempace. He was born at Saragossa, and died comparatively young at Fez in 1138. Besides commenting on various physical treatises of Aristotle's, he wrote some philosophical essays, notably one on the *Republic or Régime of the Solitary*. In its general character, and in several peculiarities, it resembles the *Republic* of Plato. The Solitary of whom Ibn-Badja speaks is the stranger who seeks for a better commonwealth than the common vulgarity of the world,—who, like some rare plant that springs up unsown in a bed of ordinary flowers, would fain regain his native air. Ibn-Badja proposed to trace the steps by which such an one taken alone, rising above his animal nature, might by abstraction and reflection elicit the universal forms of material things from the data of sense, and thus finally apprehend the pure intelligences or speculative forms. As against Algazel, he maintained the right of the intellect to rise by scientific contemplation to the philosophical heaven,—to a union with the ever-active intellect which moves the spheres. The consciousness of this union is the commonwealth of the solitary,– the enduring commonwealth of intellect in which the philosopher abides.

The same theme was developed by Ibn-Tofail in his philosophical romance, called *Hayy ibn-Jakdhân* (the Living, Son of the Waking One), best known by Pococke's Latin version, as the *Philosophus Autodidactus*. Ibn-Tofail, the Abubacer of the schoolmen, was born at Guadix in Andalusia, and died at Marocco in 1185 At the court of Jusuf he combined the offices of vizier and physician, and employed his influence to introduce younger students to the notice of the prince. Ibn-Tofail wrote on medicine and astronomy, as well as philosophy, but his romance, which has been translated into Hebrew, Latin, English, and other European languages, is his only extant work. It describes the process by which an isolated truth-seeker detaches himself from his lower passions, and raises himself above the material earth and the orbs of heaven to the forms which are the source of their movement, until he arrives at a union with the supreme intellect. The experiences of the religious mystic are paralleled with the ecstatic vision in which the philosophical hermit sees a world of pure intelligences, where birth and decease are unknown.

It was this theory which Averroes (1126–1198), the last and most famous of the thinkers of Moslem Spain, carried out to his doctrine of the unity of intellect. The whole doctrine will be discussed under the heading AVERROES; but its general purport is this. Reproducing, on one hand, the customary psychology of Aristotle as it rises gradually from the mere sense to the understanding, it emphasises, on another hand, the permanent subsistence and action of intellect apart from all materiality and from the individuals who share in the intellectual power. In the active intellect it finds the motive principle, and the full fruition of human reason. Sometimes this intellect is invested with the supremacy of the sphere beneath the moon, and connected with a more universal intelligence through a hierarchy of spiritual principles in the celestial system. Such a mind is the sole actual intellect in which the generations of thinking men live and move. In complete union with it lies their perfect beatitude; and, save as a temporary participant in the blessings of this universal form, the intellectual soul is a nonentity.

The philosophers thus characterised were in almost every case physicians; and with their medical knowledge they frequently combined studies in mathematics, astronomy, and alchemy. In all these departments they were the pupils of Greeks, whose text they accepted almost as a revelation. Their talent lay in the elaboration of details, and in correcting certain mistakes of their guides, but they never introduced any comprehensive change. Still their conjunct prosecution of physical and metaphysical studies gave them an advantage over their Latin contemporaries, with whom the schools of dialectic grew into exaggerated prominence, whilst few traces were left, as at Salerno, of the medical and scientific pursuits of the ancient world. Their acquaintance with art was another feature in favour of the Arabians. Al-Kendi, Al-Farabi, and Ibn-Badja were musicians of note: Ibn-Tofail and Ben-Gebirol were famous as poets. Their studies in the sacred law and in theology did not unduly dominate their philosophical investigations, and they combined much practical work as physicians and statesmen with an almost incredible industry in appropriating and systematising the wisdom of Greece. But the great educational value of Arabian philosophy for the later schoolmen consisted in its making them acquainted with an entire Aristotle. At the moment when it seemed as if everything had been made that could be made out of the fragments of Aristotle, and the compilations of Capella, Cassiodorus, and others, and when mysticism and scepticism seemed the only resources left for the mind, the horizon of knowledge was suddenly widened by the acquisition of a complete Aristotle. Thus the mistakes inevitable in the isolated study of an imperfect *Organon* could not henceforth be made. The real bearing of old questions, and the meaninglessness of many disputes, were seen in the new conception of Aristotelianism given by the *Metaphysics*, and other treatises. The former Realism and Nominalism were lifted into a higher phase by the principle of the universalising action of intellect—(*Intellectus in formis agit universalitatem*). The commentaries of the Arabians in this respect supplied nutriment more readily assimilated by the pupils than the pure text would have been.

Arabian philosophy, whilst it promoted the exegesis of Aristotle and increased his authority, was not less notable as the source of the separation between theology and philosophy. Speculation fell on irreligious paths. In many cases the heretical movement was due less to foreign example than to the indwelling tendencies of the dominant school of Realism. But it is not less certain that the very considerable freedom of the Arabians from theological bias served indirectly to intensify the prevailing protest against Sacerdotalism, and prepared the time when philosophy shook off its ecclesiastical vestments. In the hurry of first terror, the church struck Aristotle with the anathema launched against innovations in philosophy. The provincial council of Paris in 1209, which condemned Amalricus and his followers, as well as David of Dinant's works, forbade the study of Aristotle's Natural Philosophy, and the Commentaries. In 1215 the same prohibition was repeated, specifying the Metaphysics and Physics, and the Commentaries by the Spaniard Mauritius (*i.e.*, probably Averroes). Meanwhile Albertus Magnus and Thomas Aquinas, accepting the exegetical services of the Arabians, did their best to controvert the obnoxious doctrine of the Intellect, and to defend the orthodoxy of Aristotle against the unholy glosses of infidels. But it is doubtful whether even they kept as pure from the infection of illegitimate doctrine as they supposed. The tide meanwhile flowed in stronger and stronger. In 1270 Stephen Tempier, bishop of Paris, supported by an assembly of theologians, anathematised thirteen propositions bearing the stamp of Arabian authorship; but in 1277 the same views and others more directly offensive to Christians and theologians had to be censured again. Raymond Lully, in a dialogue with an infidel thinker, broke a lance in support of the orthodox doctrine, and carried on a crusade against the Arabians in every university; and a disciple of Thomas Aquinas drew up a list (*De Erroribus philosophorum*) of the several delusions and errors of each of the thinkers from Alkindius to Averroes. Strong in their conviction of the truth of Aristotelianism, the Arabians carried out their logical results in the theological field, and made the distinction of necessary and possible, of form and matter, the basis of conclusions in the most momentous questions. They refused to accept the doctrine of creation because it conflicted with the explanation of forms as the necessary evolution of matter. They denied the particular providence of God, because knowledge in the divine sphere did not descend to singulars. They excluded the Deity from all direct action upon the world, and substituted for a cosmic principle the active intellect,—thus holding a form of Pantheism. But all did not go the same length in their divergence from the popular creed.

The half-legendary accounts which attribute the introduction of Arabian science to Gerbert, afterwards Pope Sylvester II., to Constantinus Africanus, and to Adelard of Bath, if they have any value, refer mainly to medical science and mathematics. It was not till about the middle of the 12th century that under the patronage of Raymond, archbishop of Seville, a society of translators, with the archdeacon Dominicus Gundisalvi at their head, produced Latin versions of the *Commentaries* of Avicenna and Algazel, of the *Fons Vitæ* of Avicebron, and of several Aristotelian treatises. The working translators were converted Jews, the best known among them being Joannes Avendeath. With this effort began the chief translating epoch for Arabic works. Avicenna's *Canon of Medicine* was first translated into Latin by Gerard of Cremona (*d.* 1187), to whom versions of other medical and astronomical works are due. The movement towards introducing Arabian science and philosophy into Europe, however, culminated under the patronage of the Emperor Frederick II. (1212–1250). Partly from superiority to the narrowness of his age, and partly in the interest of his struggle with the Papacy, this *Malleus ecclesiæ Romanæ* drew to his court those savants whose pursuits were discouraged by the church, and especially students in the forbidden lore of the Arabians. He is said to have pensioned Jews for purposes of translation. One of the scholars to whom Frederick gave a welcome was Michael Scot, the first translator of Averroes. Scot had sojourned at Toledo about 1217, and had accomplished the versions of several astronomical and physical treatises, mainly, if we believe Roger Bacon, by the labours of a Jew named Andrew. But Bacon is apparently hypercritical in his estimate of the translators from the Arabic. Another protegé of Frederick's was Hermann the German (Alemannus), who, between the years 1243 and 1256, translated amongst other things a paraphrase of Al-Farabi on the *Rhetoric*, and of Averroes on the *Poetics* and *Ethics* of Aristotle. Jewish scholars held an honourable place in transmitting the Arabian commentators to the schoolmen. It was amongst them, especially in Maimonides, that Aristotelianism found refuge after the light of philosophy was extinguished in Islam; and the Jewish family of the Ben-Tibbon were mainly instrumental in making Averroes known to southern France.

Pococke, Oxon., 1663; Schmölders, *Documenta philosophiae Arabum*, Bonn, 1836, and *Essai sur les écoles philosophiques chez les Arabes*, Paris, 1842; Shahrastani, *History of Religious and Philosophical Sects*, in German translation by Haarbrücker, Halle, 1850–51; Dieterici, *Streit zwischen Mensch und Thier*, Berlin, 1858, and his other translations of the *Encyclopædia of the Brothers of Sincerity*, 1861 to 1872; Prantl, *Geschichte der Logik*, 1861, vol. ii. pp. 297–396; and the Histories of Philosophy, *e.g.*, Erdmann's, vol. i. (2d ed.), p. 295, and Ueberweg's, vol. i., English translation, London, 1872. (W. W.)

ARABIAN SEA, the name applied to the large sheet of water, really a portion of the Indian Ocean, bounded on the E. by Hindustan, on the N. by Beloochistan, on the W by Arabia and the Gulf of Aden, and on the S. by an imaginary line stretching between Cape Guardafui, in the N.E. of Africa, and Cape Comorin in Hindustan. This is the Arabian Sea proper, but under the name Gulf of Aden it penetrates between Africa and Arabia, connecting itself with the Red Sea through the Straits of Bab-el-Mandeb; while on the N.W. the Gulf of Oman, with its continuation the Persian Gulf, separates Arabia from Beloochistan and Persia. Besides these larger ramifications, there are the Gulfs of Cambay and Cutch in the N.W. of India. An interest and importance belong to this sea as forming part of the chief highway between Britain and India. The islands it contains are few and insignificant, the chief being Socotra and the Laccadives. The Arabian Sea is more or less coextensive with the *Mare Erythræum* or *Rubrum* of the ancients, although these terms seem to have been applied with considerable vagueness.

ARABICI, a sect originating about the beginning of the 3d century, which is mentioned by Augustine (*De Hæres.*, c. 83), and called also *Thnetopsychitæ* by Johannes Damascenus (*De Hæres.*, c. 99). Its founder is unknown, and its history brief and obscure. Its distinctive doctrine was a form of Christian materialism, showing itself in the belief that the soul perished and was restored to life along with the body. According to Eusebius, the Arabici were convinced of their error by Origen, and renounced it at a council held about 246 A.D.

ARACATI, a town of Brazil, in the province of Ceara, situated on the Jaguaribe, about 10 miles from its mouth. It is well built, and carries on a considerable export trade in hides and cotton. The population is stated at 26,000.

ARACHNIDA

THE Arachnida, or, popularly speaking, the Spiders and their allied forms—from ἀράχνη, a spider, and εἶδος, the form or outward appearance—constitute a well-defined group within the great branch "Articulata" of the animal kingdom, though on one side its boundary lines melt almost insensibly into the Annelides, through the family of acarids—*Pentastomides*. Linnæus and others of the older systematists included all Arachnids (as then recognised) under the class *Insecta*, Lamarck first separating them into a distinct class. A few general remarks, therefore, on the branch *Articulata*, and its subordinate groups, may be useful, to show the general relations of that under consideration.

As distinguished from the *Vertebrata*, the animals of the branch *Articulata* may be characterised generally as having (besides the marked and uniformly different position of the chief organ of circulation and the nervous chords) an external skeleton, the different parts of which, of more or less solid consistency, are articulated, or jointed to each other, and contain within their hollows the vital and other organs. Internally, threads of nervous matter, springing from enlargements or knots (*ganglia*) upon two or more central longitudinal nervous chords on the ventral side of the body traverse the different parts of it; these chords, however, end in no *one* special mass, corresponding to the brain in the *Vertebrata;* and the nervous systems composed by these ganglia vary considerably in their special structure and arrangement in the different subordinate groups.

This being the distinctive *plan* of structure in the *Articulata*, a review of the whole group shows us that this plan is carried out in two well-marked leading ways—first, *without*, and secondly, *with*, *articulated legs*, or organs of locomotion and touch. Those *without* articulated limbs constitute the *Annelides* of Lamarck, which, for our present purpose, it is sufficient to characterise as having the articulate plan of structure carried out in the general form of a more or less cylindrical, lengthened body, composed of a number of rings, segments, or transverse folds, of which the first forms the head, *but destitute of articulated limbs.* Those *with* articulated legs constitute the *Condylopa* of Latreille, or the *Insecta* of Linnæus; but the term *Insecta* being now in general use to define a subordinate group, it will be better to adopt here the name given by Latreille. In the "*Condylopa*," then, the articulated plan of structure is carried out in the form of a more or less hard body composed of different pieces, of which one, two, three, or more, are generally *leading ones ;* to this body (in general to the anterior portion of it) are attached *articulate organs of locomotion* various in number, but never, or at least very rarely, less than six. The organs of sight (when present) are always in the head, and vary in number, position, and kind. To these two leading divisions of the branch Articulata—the *Annelides* of Lamarck, and *the Condylopa* of Latreille—we may give the designation of CLASSES, since they are each respectively composed of animals which thus primarily and markedly differ in the way in which their common articulate plan of structure is carried out.

Leaving now the class Annelides, to which has been given the name "Anarthropoda," and confining our attention to the "Condylopa," or "Condylopoda" (equivalent to the "Arthropoda" of more modern authors), we find that the latter contains the four following groups—"*Insecta*," "*Myriapoda*," "*Arachnida*," and "*Crustacea*."

These all agree in the way in which, as above explained, their *general articulated plan of structure is carried out*, but they differ in the *further modifications of this plan*, that is to say, in the number, division, and size (both absolute and relative) of the different articulations of the body (including the organs of locomotion, of manducation, and of touch), and in the respective value and relation of these to each other, as well as in the modifications of their respiratory and other internal systems, and also in other important points. Differing thus from each other, these four groups, usually (three at least of them) ranked as distinct classes, yet appear to be entitled only to the rank of sub-classes, being each merely an equally subordinate group of the class "Condylopoda."

The four sub-classes of Condylopoda (or articulate-legged Annulosa) may be separately and briefly characterised thus:—

Sub-class I.—INSECTA: subject in general to metamorphosis, more or less complete, during the progress to maturity; organs of locomotion, six; body divided into three principal parts—*caput, thorax*, and *abdomen;* respiration wholly tracheal.

Sub-class II.—MYRIAPODA: not subject to metamorphosis, properly so-called; organs of locomotion above six in number (twenty-four and more) developed by degrees, and affixed to the abdominal as well as to the other (numerous) segments into which the body is divided. Although occasionally some of the anterior segments coalesce, and the head is stated to be formed by five or more modified segments, yet no one or more parts of the body can be said to be principal ones; respiration is tracheal.

Sub-class III.—ARACHNIDA: not subject to metamorphosis, properly so-called, though, as with the Myriapoda, some portions of structure among certain acarids, and to a small extent even among the *Araneidea*, are progressively developed at the various moultings of the skin. Organs of locomotion, eight, body in general divided into *two* principal parts, *cephalo-thorax* and *abdomen ;* but where (as in some groups) the abdomen is divided into more or less distinct segments no organs of locomotion are ever attached to them; respiration, where distinct organs exist, is either tracheal, pulmo-branchial, or the two coexistent.

Sub-class IV.—CRUSTACEA: without metamorphosis; organs of locomotion various in number (not less than eight or ten), and attached to some or all of the many segments, abdominal as well as others, into which the body is divided; although in numbers of crustaceans no one part of the body can be called a principal part, yet in some very large and leading groups, the portion covered by the carapace (corresponding to the cephalo-thorax in Arachnids) may well be termed the *one* principal part; the abdomen being in this case more or less rudimentary or subordinate. Respiration in the Crustacea, where distinct organs are present, is branchial.

In this view the following diagram shows the relative positions of the several leading groups of the Articulata:—

ANIMAL KINGDOM.

Branch I. Radiata. II. Mollusca. III. ARTICULATA. IV. Vertebrata.

Class I. Annelides or Anarthropoda. II. CONDYLOPODA or ARTHROPODA.

Sub-class I. Insects. II. Myriapoda. III. ARACHNIDA. IV. Crustacea.

In this diagram the Myriapoda are placed, in the position ordinarily assigned to them, between the Insects and Arachnids, but perhaps a more natural position would be after the Crustacea, for they appear to connect the Insecta and Crustacea more than they do the Insecta and Arachnida. The point, however, of the special position of any large group in a linear series is tolerably unimportant. A linear arrangement is of course the only one possible on paper, but it cannot express the numerous cross relationships that become evident when the affinities of special groups are closely studied. By placing the Myriapoda after the Crustaceans, we seem to get an ascending series in respect to the organs of locomotion: in the *Insecta*, six—always attached to the thoracic segments, in the *Arachnida*, eight—almost always attached to the thoracic segments, in the *Crustacea*, eight, ten, and upwards—frequently attached to the abdominal as well as to the thoracic segments, in the *Myriapoda*, twenty-four and more—always attached to the abdominal as well as other segments. The relation of the Myriapoda to the Crustacea through the attachment of limbs to the abdominal segments is thus expressed; and by the meeting of the two ends of the line, the always acknowledged affinity of the former to the Insecta is also expressed.

Having thus briefly explained the most obvious relationships of the Arachnida, let us now proceed to a more detailed, though still general, diagnosis of this group. And first, in respect to their *external organisation*, Arachnids are articulate animals,[1] with eight articulated legs, each in general consisting of seven joints; the head and thorax are soldered together into one piece (cephalo-thorax), from which with few exceptions the legs invariably spring. In one group of the Arachnida (*Solpugidea*) the cephalothorax is separately segmented, as it is also in one family of the *Thelyphonidea* (*Tartarides*); the rest of the body forms also one more or less homogeneous piece (abdomen). The abdomen is always more or less closely attached to the cephalo-thorax; in some instances it is soldered to the thorax, and forms with it one undivided piece, in other cases it is only joined to it by a narrow pedicle. At times, also, the abdomen constitutes a simple unsegmented portion, at other times a segmented or annulate portion of the body, occasionally, as in the true scorpions, prolonged into a segmented tail: in one small but very distinct group (*Thelyphonidea*), the abdomen is prolonged into either a simple button, a short jointed, or a more or less long setiform tail; in another large group (*Araneidea*) the abdomen terminates with organs (spinners and spinnerets) for spinning threads. The *eyes* (when present) are simple, always sessile, and placed on the fore part of the cephalothorax; they seem to represent the simple ocelli of the Insecta; the large compound eyes of that order having here no representation, the caput of Arachnids appearing to begin at a point posterior to that which bears the antennæ and compound eyes of insects. In Arachnida the number of eyes varies from two to twelve. In front of and articulated beneath the fore part of the cephalo-thorax, and moving in different planes in different groups, are two independent, variously modified, organs for seizing and compressing the insects or other substances on which Arachnids in general prey; these organs are often called mandibles, but more generally, and very appropriately, *falces*: these are considered by some systematists to be the true homologues of the antennæ[2] in insects, and to have been derived from those portions of the insect organisation by long and unceasing modification; when, however, the caput of an Arachnid (scorpion or spider, for instance) is compared with that of a coleopterous or hymenopterous insect, in which the mandibles are well developed, there seems far more reason to conclude that the *antennæ* of the insect *have no homologue at all in the Arachnid* (Claparède, *l.c. post*), but that the falces of the latter are the true representatives of the mandibles of the former. Behind the falces (and also used in manducation) are two other large movable portions of structure called maxillæ; these vary in shape and size, and form in fact lateral and hinder boundaries to the mouth, as well as an apparatus for comminuting and squeezing the food substances; from each of these maxillæ, on the outer side, springs a palpus of four or five joints, varying in structure and use. Between the maxillæ most Arachnids have also a fixed piece (*labium*) of various form, completing the hinder limits of the mouth organs, and in some (perhaps in most) there is, within the parts already named, another portion (*tongue*), not yet sufficiently observed either in regard to its form or use, but probably acting so as to hinder choking. In some Arachnidans these different parts of the mouth are soldered together and form a tolerably simple sucking apparatus, analogous to the mouth of some insects (*Hemiptera*, &c.) As observed above, Arachnids are not, in a proper sense, subject to metamorphosis: in most of them there is little real change after they leave the egg; though, in some of the lowest forms, indeed, there are after-changes by moultings of the skin, which approach the incomplete metamorphoses of some insects.

With respect to the *internal organisation* of the Arachnida, it might perhaps be enough here to refer to the more detailed accounts given further on, where the separate *orders* are under consideration; but the following summary will probably make our general view of the whole sub-class more complete.

Muscular System.—Of this it is enough to say that it is similar to that of the rest of the Articulata, consisting of flexor and extensor muscles, situated within the hollows of the limbs, besides groups of fibres by which the epidermis and parts within it are connected and held together. On the outer surface these groups frequently show, at their points of union, boss-like marks or foveæ, or impressed spots of various forms and sizes, often presenting by their position distinctive peculiarities of form; it is probable that many others of the external specific markings are dependent on the course and position of the muscular fibres, as well as of the heart and other organs.

Circulatory System.—The vital fluid is circulated by means of an elongated muscular vessel or heart, varying in form, and, instead of being placed, as in the Vertebrata, on the ventral side of the body, extending along the back of the abdomen. This vessel is often divided into chambers[3] or compartments by valves, having also valvular orifices on its upper side for the flowing in of the fluid (Newport), and giving off vessels (arteries) for its distribution to the rest of the body. In the lower forms, however, of Arachnids (among the *Acaridea*) no such principal muscular vessel is found, the vital fluid being in such cases supposed to circulate generally in the body, and to be distributed irregularly into different portions by the muscular movements of the intestinal canal.

Respiratory System.—Arachnids breathe by means of *tracheæ* (spiracular tubes, as in the Insecta), as well as by *pulmo-branchiæ*, said to be a kind of compound of the gill of fish and the lung of mammals, though in reality there seems better reason, as we shall see further on (p. 293), to consider the pulmo-branchiæ as merely peculiarly modified tracheæ;

[1] Embryology shows that the first pair of legs in arachnids are homologous to the labial palpi of insects (Claparède, *l. c. post*). This is strictly true according to their use in one order—Thelyphonidea; and in many of the Araneidea also these legs are chiefly used for feeling and exploring the obstacles in their way.

[2] Hence their name among French arachnologists, "Antennes-Pinces."

[3] L. Dufour (*Savants étrangers*, xiv pp. 594–609) controverts this in respect to the Scorpionides, and apparently with success, establishing the fact of the dorsal vessel being simple and unchambered.

both these organs have external orifices (stigmata) variously situated, but commonly in some part of the abdomen. In some Arachnids (certain groups of the *Araneidea*) respiration is effected by both of the above organs; while in others (certain of the *Acaridea*) no distinct organs of respiration exist.

Digestive System.—Digestion is effected by a simple alimentary tube or canal running from the mouth to the anus. This tube is various in its form, as well as in the intestines issuing from it; in some groups, as the *Araneidea* and *Acaridea*, the above canal has large lateral cæcal appendages; in others (*Scorpionides* and *Thelyphonides*) the alimentary canal has no such lateral enlargements. In some Arachnids there have also been found a liver (or mass of substance in the abdomen exercising the functions of a liver), an organ performing the part of kidneys, and salivary glands, often of large size, while in others no distinct organs of digestion exist.

Nervous System.—This consists of ganglia or nerve-knots, formed by enlargements of longitudinal nervous cords (generally two in number), differing in position and in the nerves issuing from them. In one large group (*Acaridea*) where the abdomen usurps, as it were, the place of all the rest of the body, there is no longitudinal nerve cord; a single nerve mass occupies the interior of the abdomen, and sends forth nerves to the various surrounding parts.

Generative System.—Generation is effected by two distinct and separate sexes, the single exception known being the *Tardigrada*, a group of *Acaridea* approaching nearly to the Entozoa, and said to be hermaphrodite. In females the parts of generation consist of two sacs (ovaria), one on each side of the alimentary canal. These have a common external orifice (vulva), various in its shape, beneath the anterior extremity of the abdomen; and connected with this opening there is frequently an epigyne, or ovipositor, often of some length, and of characteristic form. In *males* (except among the phalangids and scorpions) there is no intromittent organ,—the generative parts consisting of two long tubes, similarly situated to the ovaria in females, in which the seminal fluid is secreted; these tubes end in a simple external, very minute orifice, in a similar situation to the vulva of the female.

Arachnids are either oviparous or ovo-viviparous. As before observed, they undergo no proper metamorphosis, but as growth takes place there are more or fewer successive moultings of the skin; and complete development of all the parts does not occur until the last moult, when the creature becomes adult, and so fitted to perpetuate its kind.

With regard to the position held by Arachnids in the great scheme of nature, it seems, from the considerations shortly entered into above, undeniable that they are very closely linked to the rest of the Articulata by much, both of external and internal structure, common to the whole branch. The office they subserve is evidently the keeping down of the superabundant supply of the insect world; some even operating to check the too rapid advance of higher animals.

Assuming that the operation, in some shape or other, of evolution has brought the different groups of Articulata to the varied forms and conditions they now respectively present, it is plain that the higher, at least, of the arachnidous orders must, in all probability, have been modified from some one or more of the other groups, perhaps in the main from the Insecta and Myriapoda,—certainly not the Insecta, for instance, from the Arachnida. Thus, we should define Arachnids, generally, to be insects modified for the purpose of preying upon their congeners; while some of the lower forms of Arachnids, such as *Demodex*, *Tardigrada*, and *Pentastoma*, carry us back to the remote past, before the branch Articulata, in any of its great groups, had attained more than a very slight progress towards its present dignified and highly organised forms.

The above being a general summary of the external and internal organisation of the Arachnida, an examination of the whole group shows us that their different characters, and the ways in which their articulated plan of structure is carried out, are variously correlated and modified, forming structural complications of several marked kinds, whence we get the different *orders*, being the next subordinate groups, into which Arachnids are divided. These *orders* are seven in number, and form so many well-defined groups, but of very different extent. Advancing from the more simple to the more highly organised, we begin with the *Acaridea*, comprising the mites and ticks, and including also the *Tardigradides*, *Pentastomides*, as well as *Demodex*. The second order is that of the *Pycnogonidea*, marine parasites, which, in a certain plane, appear to connect the Acaridea with the next or third order, *Phalangidea*; these last are popularly known as "Harvest-men." Next to them, and forming the fourth order, come the *Solpugidea*, a small but very distinct group, constituting a link in one plane between the *Phalangidea* and *Scorpionidea*, which last, including the Chelifers, or False Scorpions, form the fifth order. Not far removed from these is the sixth order, *Thelyphonidea*, comprising groups which partake of the characters both of the Scorpionidea and of the next—the seventh and last—order, *Araneidea*, or true Spiders.

Sub-Class.—ARACHNIDA

Orders.—I. Acaridea. II. Pycnogonidea. III. Phalangidea. IV. Solpugidea. V. Scorpionidea. VI. Thelyphonidea. VII. Araneidea.

The following abstract shows the chief ordinal characters of these seven groups of Arachnids:—

Order I. ACARIDEA.—Cephalo-thorax and abdomen united so as to form one piece, generally without mark of union; palpi and falces variable in structure; the several parts of the mouth often united; legs terminating variously, generally eight in number, sometimes only six in the immature state, and in one or two instances but four, even when adult; eyes, when present, variable in number (2 to 6), and placed on the cephalo-thorax; respiration, when proper organs for it exist, wholly tracheal; nervous matter gathered into one large mass, or ganglion; reproduction ovo-viviparous as well as oviparous. Maturity is reached by quasi, or imperfect, metamorphoses in some of the groups.

Order II. PYCNOGONIDEA.—Cephalo-thorax segmented, linear; abdomen rudimentary, forming merely a small terminal segment to the cephalo-thorax; the mouth consisting of the termination of a tubular article forming the head, sometimes accompanied by some more or less distinct parts; legs eight, multi-articulate; in females a supernumerary pair, between the first two and used for bearing ova; organs of respiration, none; metamorphosis imperfect, as in the last order.

Order III. PHALANGIDEA.—Cephalo-thorax and abdomen of tolerably equal size, and united throughout their whole breadth, but the junctional line evidently marked; abdomen annulate or segmentate, caused by transverse folds in the epidermis; falces two-jointed, didactyle; legs in general inordinately long, and very slender; the two terminal joints multi-articulate, and ending with claws; eyes two, on the vertex of the cephalo-thorax; respiration tracheal; reproduction oviparous; no metamorphosis of even an imperfect kind.

Order IV. Solpugidea.—Cephalo-thorax distinct from the abdomen and segmented, the first segment forming the head; abdomen annulate; falces one-jointed, didactyle; palpi terminating with a capsule containing a peculiar organ, the use of which is not yet known; eyes two, on a small eminence at the fore part of the head in the medial line; respiration tracheal; legs terminating with two curved fingers; manner of progressive growth unknown.

Order V. Scorpionidea.—Cephalo-thorax formed of one undivided piece, united to the abdomen throughout its entire breadth; abdomen annulate, prolonged (in one of the families) into a segmented tail, ending with a poison bulb armed with a sharp perforated point, through which the poison is emitted; falces didactylous; palpi terminating with a didactyle claw; eyes variable in number, two to twelve, variously grouped on the fore part of the cephalo-thorax; respiration, in one family, tracheal, in another, pulmo-branchial; ganglia several, distributed along the nervous chord; reproduction, in some oviparous, in others ovo-viviparous; organs for spinning beneath the fore part of the abdomen in one family; no metamorphosis.

Order VI. Thelyphonidea.—Cephalo-thorax undivided, but its segmental structure generally visible in grooves and furrows, following the course of the soldered joints; abdomen annulate, joined to the cephalo-thorax by a pedicle; palpi very strong, didactylous (in a modified form); falces monodactylous; legs of the first pair excessively long, antenniform, the last joints very fine, multi-articulate, and devoid of a terminal claw; eyes, when present, eight, disposed in three groups on the fore part of the cephalo-thorax; abdomen either terminating with a button-like segment, a short two-jointed tail, or a multi-articulate setiform one; respiration pulmo-branchial; manner of progressive development unknown. In one family, ganglia two, closely united; in others unknown.

Order VII. Araneidea.—Cephalo-thorax undivided, but traces of segmentation commonly more or less visible, united to the abdomen by a narrow pedicle; abdomen without segments or annuli, ending with organs for spinning; falces monodactylous; palpi more or less filiform in males, with the last joint more or less complicated in structure, and used in copulation, terminating in females (but not invariably) with a claw or claws, sometimes pectinated; legs terminating with two or three curved claws, and, except the third (which is rarely so), generally more or less pectinated; ganglia two or three in number; respiration tracheal, as well as pulmo-branchial; reproduction oviparous.

We have thus far obtained a general view of the leading groups of the sub-class Arachnida, both in respect to its relation to collateral groups of equal value, and the relation of its own members to each other, and also a synoptical view of the leading characteristics of the seven orders into which Arachnids may be divided. We now propose to touch shortly, but in greater detail, upon each of those orders, and, as far as our limits will permit, upon the families and genera comprised in them, adding a few general remarks upon each group.

Order I.—Acaridea.

The inclusion in this order of such aberrant forms as Demodex, Pentastoma, and Tardigrada, somewhat destroys its homogeneity; undoubtedly they indicate a passage from the Annelides (Anarthropoda) to the Arthropoda, but whether it would not be more consistent with a strict scientific method to separate the two latter, at least, from the Acaridea, and make each the type of a distinct order, is a point for the future consideration of systematists. At present the balance of opinion appears to be for including them as the lowest transitional forms of the lowest order of Arachnids. With regard to the position of Tardigrada, see Packard's *Guide to the Study of Insects*, p. 668, where Claparède is quoted from his *Studien an Acariden*; also *Introduction to the Classification of Animals*, Huxley, pp. 123–124, where the position of Pentastomides is also considered. See likewise on this, Cobbold's *Entozoa*, part iii. pp. 393–402, where reference is made to Leuckart's *Bau- und Entwicklungsgeschichte der Pentastomiden.*

Owing to the excessively small size of most of the Acaridea, and their obscure mode of existence, much of their economy and internal structure is yet unknown. The following is an endeavour to present their characters in somewhat greater detail than in the short abstract given above.

External Structure.—In their general form the Acaridea are more or less round, oblong, or oval; the integument in some is soft, in others coriaceous, and some are quite hard, like a Coleopterous insect.

The cephalo-thorax and abdomen are consolidated into one piece devoid of articulations; not only is the head, as in other Arachnids, soldered to the thorax, but the portion (cephalo-thorax) formed by this union is generally joined invisibly to the abdomen, which is consequently merged in the general covering of the body. In the family Bdellides, however, and also in some other instances, the junctional points of the different parts of the body are visible enough. The legs are eight in number in the mature acarid, except in Pentastoma, which in a state of maturity has none (fig. 1)—the four abnormal-looking legs visible in the young state disappearing in the adult (fig. 2). Many other Acaridea have six legs only until the last moult, when maturity is attained, one or two, even in the adult state, being said to have but four. Each leg consists in general of seven joints, and the tarsi end, in some, with two movable hooks; in others the tarsus is dilated at its extremity as if for feeling with, while in some of those whose habits are aquatic it is expanded; in short, the structure of this part is very various, and adapted to the habits of the different genera.[1] Dugès distinguishes the different kinds of legs as follows:—1. *Palpatorii*; 2. *Gressorii*; 3. *Remigantes*; 4. *Cursorii*; 5. *Textorii*; 6. *Carunculati.*

The parts of the *mouth* consist of two movable pieces, or falces, in front of which is another piece (labium); on each side of the labium is a strong piece (maxilla), and from the outer side of each of the maxillæ springs a palpus of four or five joints. The different forms and structure of these parts give good characters for the subordinate divisions of the Acaridea. The mouth parts in the species of Acaridea present greater variety than is to be found in any other order, no doubt owing to the greater variation in their mode of existence. In some instances the falces, maxillæ, and labium form, by their union, a sort of tube or proboscis fitted for piercing, holding on to, and sucking the juices of their prey; when not so united, the falces are terminated variously by a didactyle claw, somewhat like the claw of crab, or by a movable fang (sometimes twofold) as in the true spiders (Araneidea), or they consist of "two long styles, which by moving backwards and forwards alternately, perforate the substance of their prey."

The *palpi* of Acaridians are also variously formed, and, like the legs, have been minutely and well distinguished by Dugès, who (*l.c.*) divides them into seven kinds.—1. *Rapaces*, armed with hooks for seizing hold with. 2.

[1] Dugès's "Recherches sur l'ordre des Acariens," *Ann. Sc. Nat.*, 2e ser. t. i. ed. 2

Anchorarii, found in aquatic species, and used for retaining their position by means of terminating points. 3. *Fusiformes*, without any claw on the last joint. 4. *Filiformes*, as their name implies, filiform, or not at all tumid. 5. *Antenniformes*, chiefly differing from the last in their greater length. 6. *Valvæformes*, flattened, or excavated, or sheathed in form. 7. *Adnati*, or united throughout the greater part of their length to the labium, and always slightly developed.

The *eyes* in very many Acaridians are entirely wanting; When present they vary in number, being generally two, four, or six, and are placed on the cephalo-thorax; sometimes, as in the family Hydrachnides, they apparently consist of mere spots of pigment beneath the cuticle;[1] in some other cases there is but one eye, which is composed of a varying number of small facets.

INTERNAL STRUCTURE.—The *Organs of Digestion* consist, in many species, of a short intestinal canal, which branches out into lateral cæca, "*à sa partie stomachale*," and has an anal orifice on the lower side of the abdomen, more or less near to its posterior extremity (Walck., *Ins. Apt.*, iii. 135). The researches of Dujardin (*Ann. Sc. Nat.* 1845, tom. iii. p. 14) show in two families (Hydrachnides and Trombidides) a curious modification of these organs. In this, the juices upon which these creatures exist are sucked in, apparently, into simple cavities in the substance of the body; these cavities are without walls of any kind, and from them the juices circulate through the body, and thus form its support.

The *Organs of Respiration* consist generally of tracheæ, communicating outwardly with the air by means of minute orifices, "stigmata," which, in the genus Oribates, are situated between the first and second pairs of legs. In one numerous family (*Acarides*) no special organs for breathing exist, respiration being apparently effected by the general surface of the body. Different genera exhibit these two modes of respiration in various forms of union. M. Dujardin (*l.c.*, p. 17) speaks of tracheæ, in the family Trombidides, having an external orifice at the base of the falces on their upper side,—the use of these tracheæ being for expiration, while inspiration is performed through the general surface of the body and the plumose hairs attached to it, or, as in the family Hydrachnides, by "stomata," *i.e.*, apertures covered with very delicate membrane.

The *Nervous System* in Acarids is ganglionic, as in the rest of the Articulata; and, as we should expect from the simple form of the body (occasioned, as we have seen, by the almost complete fusion of the head and thorax in the abdomen) extremely simple. In the families Trombidides and Acarides, and probably in the rest also, the nervous apparatus consists of "one large globular ganglion, from which nervous filaments are given off, both before and behind."

With regard to the *Circulatory System* in the Acaridea too little, apparently, is yet known to make it possible to speak certainly. It is highly improbable but that, in some of the higher groups, distinct organs exist, though such do not yet appear to have been discovered. The results hitherto are negative; no traces of circulatory organs have been found in such of the lower acarids as have been subjected to minute dissection, and hence the supposition[2] that the intestinal canal, by means of muscular movements and contractions, operates in the irregular propulsion of the vital fluid to various parts of the body.

The *Reproductive System* of the Acaridea is very simple. The external organs consist of an opening on the ventral surface, generally between the coxæ of the hinder pair of legs. Acarids are both oviparous and ovo-viviparous; in the latter case the young are produced through a large orifice or vulva nearly one-third of the length of the body, and closed by two valves. Some are supposed to be hermaphrodite, but this, though true of the Pentastomides, is uncertain in respect to others of this order. Parthenogenesis, however, certainly exists in some species. The ova appear commonly to be produced in the substance of the general tissue of the body without the presence of any ovarian apparatus with distinct walls; it is certain, however, that ovaries are present in some species—in the family Trombidides, for instance, in which a tubular double branched ovarium was discovered by Dujardin. Some of the Acaridea, as Tetranychus, produce silk, and spin webs, but the silk-secreting organs have yet to be discovered; neither do any external organs, such as spinnerets, appear yet to have been noticed. The development of Acaridians from the egg is a subject of great interest and importance, for which, see Claparède's *Studies on Mites* (*Studien ar Acariden*), and Siebold in *Kölliker's Journ. Sc. Zool.*, 1868, part iv.

GENERAL OBSERVATIONS.—Acaridians are universally distributed; they are to be found under stones, dead leaves, or bark of trees, in the ground, in water, in unrefined sugar, upon dried meat, fruits, cheese, and putrid animal matters, upon all of which they feed. Some are parasitic, both externally and internally, in the flesh of different animals, living upon the juices of the creatures they infest. One species, *Sarcoptes Scabiei*, is the cause of the disease called the "itch;" another is our troublesome "Harvest-bug." Some are parasitic upon insects of different kinds; others are said to have been found in the brain and eyes of man. All are small, great numbers almost microscopic; the smaller kinds, particularly of the Acarides, are very difficult to preserve as cabinet objects, and from this, as well as from their minuteness, the order, generally, does not receive that attention to which, from their diversified forms and modes of life, Acaridians are certainly entitled.

From various considerations of structure, the Acaridea may be divided into ten families, each containing one or more genera. These families may shortly be characterised as follows:—

Fam. 1. *Pentastomides.*—Body annulate, vermiform, lancet-shaped; the segments of the cephalo-thorax continuous with the body, and furnished with four strong claws or rudimentary legs; this appears (Rolleston, *Forms of Animal Life*, p. 118) to be the larva or immature state, the adult form being destitute of limbs (which are replaced by four hooks—two on each side of the mouth), and reversing the ordinary progress of many acarids, from a fewer to a larger number of legs; organs of respiration and circulation, none (Huxley). On this abnormal family, of which one genus and eighteen species have been described, see Cobbold's *Entozoa*, pp. 393–402, and authorities there quoted. (See figs. 1, 2.)

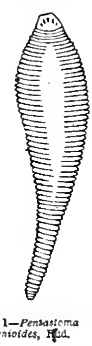


FIG. 1—*Pentastoma tænioides*, Rud.

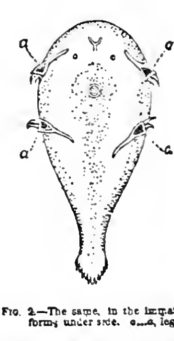

FIG. 2—The same, in the immature form; under side. a...a, legs.

[1] Rymer Jones, *An. King.*, 2d ed. p. 411.
[2] See Packard's *Guide to the Study of Insects*, p. 627.

Fam. 2. *Tanurides* (ταναός, long, οὐρά, a tail).—The type of this family is *Demodex folliculorum*, Simon (fig. 3), a very curious parasite found in the follicles of the human nose—hence its specific name. It is long and slender; the abdomen drawn out into a wormlike tail; the fore part or cephalo-thorax has in the adult state four pairs of rudimentary legs, in the immature state three pairs. This is one of the lowest forms of acaridians, and presents in its adult state the immature vermiform appearance of the higher genus Typhlodromus (Packard, *l.c.*)

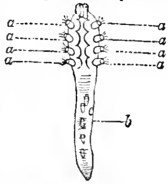

FIG. 3.—*Demodex folliculorum*, Simon; under side. *a...a*, rudimentary legs; *b*, abdomen.

Fam. 3. *Tardigradides*.—Body cylindrical, vermiform, but with no distinct abdomen; it is furnished throughout its whole length with four pairs of rudimentary limbs, of which the fourth pair is quite at the posterior extremity; eyes, two; falces, style-like. These animals are microscopic in size and aquatic in habits; they are hermaphrodite, and are now generally held to be acarids of a very low grade (Packard, *l.c.*, p. 668). Several genera have been characterised. Fig. 4 represents *Milnesium tardigradum*, Schrank.

Fam. 4. *Acarides*.—We now come to the more typical forms of Acaridea.

The family Acarides have a soft, thin-skinned body, with the thoracic junction often visible; falces either scissor-like or styliform; maxillæ obsolete; legs of the two first pairs often widely distant from those of the hinder ones; in some lowly organised forms, "face-mites," four legs only are found; perhaps these are the immature form of some other species (?); eyes, none. In this family are included the cheese, itch, and sugar mites, with numerous others parasitic on various animals. Some forms, as *Heteropus ventricosus* (Newport), *Dermaleichus*, and *Typhlodromus*, particularly in the immature state, exhibit an evident link between the last two families and the higher acarids; on the agamic reproduction of a species of this family (Cheyletus) see R. Beck in *Q. J. Microsc. Sc.*, April 1866; also Newman's *Zoologist*, 2 ser., i. p. 236.

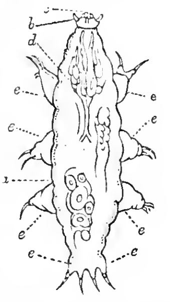

FIG. 4.—*Milnesium tardigradum*, Schrank. *a*, ovary; *b*, palpi (?); *c*, parts of mouth; *d*, alimentary canal; *e...e*, legs (rudimentary).

Fam. 5. *Oribatides*.—Body hard and horny; the thoracic junctions visible; form of the abdomen, round, globular, oval, quadrangular, or hemispherical; palpi, short; maxillæ, large and toothed; eyes, almost obsolete; cephalo-thorax, generally with two wing-like projections and two or three cup-shaped pedicellated stigmata on the edge, leading to the respiratory tubes. The Oribatides in general live on vegetable matter, and several genera have been characterised. The immature forms of many species vary greatly from the adults, so that numbers have been described as distinct species. See on this family an elaborate paper by M. H. Nicolet, in the *Arch. du Mus.*, t. vii. pp. 383–482, pls. 24–33.

Fam. 6. *Gamasides*.—Body, oval, flattened; epidermis, dense; falces, scissor-like; maxillæ, free; legs, equal in size and of similar form; eyes, obsolete. There are several genera of this family parasitic on various animals.

Fam. 7. *Ixodides*.—Body, round, oval, or somewhat oblong, of a leathery consistency; palpi, short, three or four jointed; falces, saw-like, and, with the other parts of the mouth, joining in the formation of a beak for thrusting into and holding on to their prey. Eyes, often obsolete; legs weak. On the generation of Ixodes, see a paper by Prof. Gené, communicated by A. Tulk to *Ann. and Mag. N. H.*, No. 188, Sept. 1846, p. 160. When gorged with the juices of their victim the abdomen attains an enormous size, and appears almost to obliterate all the rest of the body. In this family are comprised the "ticks" (Ixodes), which are often so tormenting to mankind, and domestic and other animals (figs. 5, 6). Among these ticks is included also the noted genus *Argas*, of which a species, *A. reflexus* (Latr.), has lately been found at Canterbury, England. Some of the largest known acarids are contained in this family.

Fam. 8. *Hydrachnides*, or water-mites.—Body, oval, or almost globular; palpi, short; legs, ciliated for the purpose of swimming; eyes, two. These acarids are found in salt as well as in fresh water. Some are parasitic, when immature, on water-bugs and water-beetles; others, through life, on the gills of the fresh-water mussel.

Fam. 9. *Trombidides*.—Body, stout, round, or oval, and often somewhat oblong; frequently broader before than behind; sometimes clothed densely with a kind of pubescence. The two hinder pairs of legs far removed from the two fore pairs. Eyes, two. The colour of the species of this family is generally of a bright red.

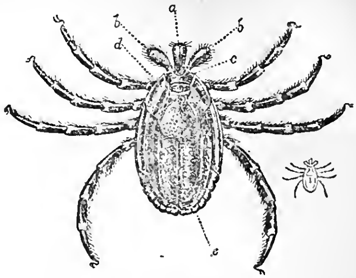

FIG. 5.—*Ixodes ægyptius*, Savigny. *a*, falces; *b*, *b*, palpi; *c*, caput; *d*, cephalothorax, *e*, abdomen.

scarlet, or yellowish. Among them is the red mite, *Tetranychus telarius* (Linn.), popularly called the "red-spider," which infests hothouses.

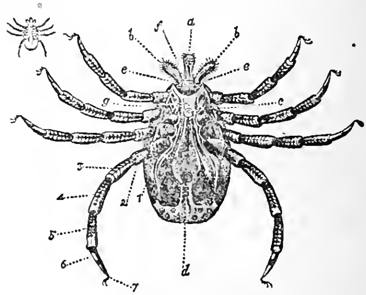

FIG. 6.—The same; under side. *a*, falces; *b*, *b*, palpi; *c*, genital aperture; *d*, anal orifice; *e*, *e*, *f*, maxillæ and labium soldered together; *g*, sternum.

Fam. 10. *Bdellides*.—Body, oblong-oval, showing the junctions of caput, thorax, and abdomen; palpi, long; eyes, two to six, sometimes obsolete; legs, long and strong; parts of the mouth forming a tapering pointed beak of greater or less length, and looking like a prolongation of the caput. The Bdellides live in damp places, under moss, &c., and on the floors of caverns.

The above characters of the Acaridian Families are abridged chiefly from A. S. Packard's *Guide to the Study of Insects*. Besides Claparède's *Studien an Acariden*, and Nicolet's *Mémoire* on *Oribatides*, and other works above noted, may be mentioned Dr C. Heller on the anatomy of *Argas persicus*, *Sitzungsb. d. K. Akad. d. W. Math. Naturw. Cl.* Bd. xxx. No. 16, 1858, pp. 297–326, Taf. i.–iv.; Charles Robin's *Mémoire zoologique et anatomique sur diverses espèces d'Acariens de la Famille des Sarcoptes*, 1860, with 8 plates; also by same author, "Mémoire sur les Sarcoptes avicoles, et sur les metamorphoses des Acariens," *Comptes Rendus*, tom. lxvi. pp. 776–786; H. A. Pagenstecker, *Beiträge zur Anatomie der Milben*, Heft 1, "Trombidium," 2 Taf. 32 pp., Leipsic, W. Engelman, 1860; P. J. van Beneden, "Recherches sur l'histoire naturelle et la développement de l'Atax Ypsilophorus (*Hydrachna concharum*)," *Nouv. Mém. de l'Acad. de Belge.*, tom. xxiv. 1850 (24 pp. ed. 1. pl.) Of the older works on Acaridea may be mentioned that of Hermann, *Mémoire Apterologique*, in fol., Strasbourg, 1804; and P. Gervais, in Walckenaer's *Ins. Apt.*, tom. iii. pp. 132–288, pls. 31–36 and 38, 1844; Doyère, "Mémoire sur les Tardigrades," *Ann. Sc. Nat.*, 2 ser. "Zool.," tom. xiv. 1840, pp. 269–361; Suite, *Ibid.*, tom. xvii. 1842, pp. 193–205, and tom. xviii. 1842, pp. 5–35, with 8 plates; P. J. van Beneden, "Recherches sur l'organization et la développement des Linguatules (*Pentastoma*, Rud.) suivies," &c., 39 pp. with 1 pl., in *Nouv. Mém. de l'Acad. de Belge*, tom. xxiii. 1849.

Order II.—PYCNOGONIDEA.

The creatures of this order form a small group which it appears now necessary to receive among the Arachnida, though their true position has been hitherto (and to some extent still is) a matter of much difference of opinion among naturalists. They seem to connect the more typical Arachnida with the Crustacea, and also to form a passage from the Acaridea to the Phalangidea. It appears, however, when their peculiar structure, both external and internal, is considered, impossible to include them within either of those orders; it is therefore proposed here to constitute them a separate order between the acarids and phalangids. The characters of the order are—

EXTERNAL STRUCTURE.—*Body*, linear, composed of four segments; *caput*, tubular, in form of a beak or proboscis, and either simple, or ending with palpi and mouth organs; *abdomen*, rudimentary; *legs*, eight (each thoracic segment bearing a pair), very long, and consisting of eight to nine joints, terminating with a claw or claws. In the immature (so-called larval) state the legs are four only in number. The females have a supernumerary pair between those of the first pair, used for carrying the ova. *Palpi*, when present, filiform, and composed of five to nine joints terminating with a claw. *Eyes*, four.

With regard to their *internal structure*, the Pycnogonidea have a dorsal vessel (circulatory apparatus) divided into chambers, a stomach sending forth cæcal prolongations into the legs and palpi, an abdominal intestine with dilated cloaca, and a nervous system, consisting of a cephalic and opththalmic ganglia, closely united together and joined by the œsophagian fillet to the abdominal ganglia, which are four in number, of large size, sessile, and emitting from their lateral extremities nerves into the legs (Cuvier's *Règn. An.*, edition cited *post*, pl. 22), but no organs of respiration (Huxley, *l.c.*, and Cuvier's *Règn. An.*, *l.c.*)

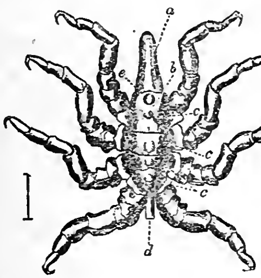

FIG. 7.

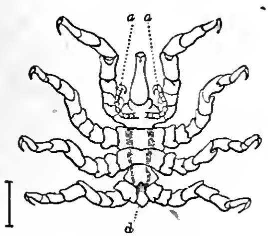

Fig. 8.

FIG. 7.—*Pycnogonum littorale*, Müller. *a*, parts of mouth, forming a beak; *b* caput; *c...c*, thoracic segments; *d*, rudimentary abdomen; *e*, eyes
FIG. 8.—The same; under side. *a*, *a*, supernumerary pair of legs.

This order contains but one family, *Pycnogonides*, divided into several genera—Pycnogonum, Phoxichilus, Nymphon, and Ammothea. Some of the species are parasitic on cetaceous animals, others are found secreted among seaweed along the sea-shore, and feed on small marine animals. Some are British, and others exotic.

The genera may be thus shortly characterised.

Genus *Pycnogonum* (Brunnich).—Body short and thick; legs, short, strong; without either falces or palpi. The species of this genus are parasitic on the cetacea. Figs. 7, 8, *P. littorale* (Müller).

Genus *Phoxichilus* (Latr.)—Body narrow; legs of great length; falces present, but no palpi.

Genus *Nymphon* (Fabr.)—Resembles Phoxichilus in the narrow body and long legs, which are also slender, as well as in having falces; but in the present genus there are also two palpi, each of five joints. Fig. 9, *Nymphon coccineum* (Johnston).

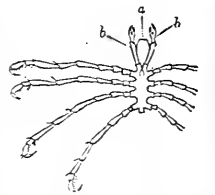

FIG. 9.—*Nymphon coccineum*, Johnston; under side. *a*, head; *b*, *b*, palpi.

Genus *Ammothea* (Leach).—Body short and rather broad; legs long; beak of great size and length; much longer than the falces, which are short. Palpi 9-jointed, the third joint much the longest; terminal tarsal claws double, and of unequal size. Supernumerary legs 9-jointed, and inserted under the first pair of legs behind the beak.

The latest authority in regard to their systematic position, *i.e.*, whether Crustacean or Arachnidan, is Dr Anton Dohrn, who says in a memoir, "Ueber Entwicklung und Bau der Pycnogoniden" (contained in a publication, entitled *Untersuchungen über Bau und Entwicklung der Arthropoden*, Leipsic, Engleman, 1870): "Die Pycnogoniden sind weder Arachniden noch Crustaceen." Dr Dohrn enters fully into the development and structure of *Pycnogonum littorale*, and of a species of another genus formed out of Phoxichilus, *Achelia lævis*. The present writer has not, however, had an opportunity of studying this memoir

Order III.—PHALANGIDEA.

The Phalangidea present a very well defined and compact group, though the transition, in one plane, from the Acaridea, through the families Cyphophthalmides and Trogulides, is tolerably apparent, while in another plane they show evident affinity to the Pycnogonides. The following are more detailed characters of the order:—

EXTERNAL STRUCTURE.—The *body* is of a more or less round, oval, or oblong, and sometimes quadrangular form; the integument is either hard and horny, or coriaceous, and generally destitute of hairs, but often tuberculous and armed with spines.

The *cephalo-thorax* and *abdomen* are united throughout their whole breadth, the junction frequently shown by a slight constriction, but always visible from a strongly-marked groove or ridge; the upper side of the cephalo-thorax, and sometimes of the abdomen, is frequently furnished with spines, sharp teeth, or tubercles. The abdomen is articulate, or segmented in a modified form, from several more or less strongly developed transverse foldings in the epidermis.

The *mouth organs* are rather complex (fig. 11), consisting of three pairs of maxillæ, above which is a tongue (*languette*); and below the maxillæ is a membranous lip (*labium*). From the first pair of these maxillæ there issue two five jointed palpi, the intermediate joints of which often exhibit processes or branches, the last or digital joints ending with a claw. The other two pairs of maxillæ support the basal joints of the two first pairs of legs. The presence of these supernumerary, or crural, maxillæ strongly supports the idea long since advanced by Savigny and others, that the palpi are but modified legs (see, however, note 1, p. 272 *supra*); the same idea being also raised in regard to the Thelyphonidea and Solpugidea by the use as palpi of the first pair of legs, which are in fact completely palpiform, and differ markedly from the rest in their structure. Above these parts, directly in front of the upper extremity of the cephalo-thorax, are two *falces*, each of which consists of two, or (in *Cyphophthalmides*, G. Joseph) three joints;

the second joint terminates with a didactyle claw or pair of pincers, formed by a movable claw acting in opposition to a fixed one.

The *falces* vary greatly in their size and development. The terminal joint is sometimes articulated to the basal one at the extremity of its longer axis or at its end; at other times it is attached by its shorter axis, or more or less near the middle. In some species they are furnished with processes or horny prolongations, differing in size and form in different species; this is, however, only a modification of the last mentioned mode of articulation.

The *legs* are, in most species, very long and slender; in some groups they are, however, shorter and stronger, while in others they are of extreme length and tenuity. They are eight in number; the seven normal joints, of which each is composed, may be more properly described as consisting of five invariable and two variable ones; the sixth (or metatarsus) being divided into several immovable divisions, and the seventh (or tarsus) subdivided into a greater or less number of minute movable articulations, the terminal one furnished with one or two fine claws. The legs are often armed (some, at least, of their joints) with strong spines and spiny processes; this is particularly the case in the family Gonyleptides. The first joint (coxa) of each leg is immovable, being fixed to the side and under part of the cephalo-thorax. Between the fixed (or basal) joints of the legs is an oblong, or at times somewhat obtusely triangular, *sternal plate*, divided at its base from the abdomen by a transverse groove; the anterior extremity is free, and beneath it is concealed (according to the sex) the penis of the male, or the ovipositor of the female; in some species of Phalangides these organs are of great length and varied in form; this sternal plate forms the lower side of the cephalo-thorax. The *eyes*, two or eight[1] in number, are generally of large size, and situated on the sides of a common eminence on the upper side of the cephalo-thorax; this eminence is often armed with spines and tubercles.

INTERNAL STRUCTURE.—*Muscular System.*—Every one who has seen the mode in which the Phalangides run would naturally suppose that the muscles required to keep the body raised and balanced between their long slender legs in rapid course must be exceedingly strong; and this is found to be the case. The muscles are of large size, consisting of numerous strong "fasciculi," which arise from the interior of the basal joints (coxæ) of the legs, and, almost entirely filling up their hollows, pass on into the next joint (trochanter), and so on to the end of the second part of the tibiæ; thence two long delicate tendons, continuing forwards, traverse the whole length of the tarsal joints, running along their under surface. The muscles by which the falces and palpi are worked consist of an *elevator* and a, somewhat larger, *depressor* for each. Other muscles and muscular fibres connected with other parts and organs are minutely described by A. Tulk,[2] whose descriptions, however, cannot be usefully abridged, and are too extensive and detailed for our present space.

Organs of Digestion.—These consist of a simple longitudinal pouch forming the stomach or main intestinal canal, contracted at each end, enlarged in the middle, and giving off on all sides numerous lateral pouches or cæca of different sizes, to the number, in *Phalangium opilio* (Latr.), of thirty. These are minutely detailed by Tulk, who divides them into—(1), those on the dorsal surface of the main canal; (2), those on its ventral surface; (3), those on its sides. The pharyngeal tube and œsophageal canal are modified so as to be qualified not only for the passage of simple fluids, but also for solid substances; these first, however, having undergone a process of quasi-mastication by means of the external parts of the mouth. At the opposite end of the alimentary canal a simple, short intestine connects it with the anus, the external aperture of which is situated at the hinder extremity of the abdomen. With regard to the office of the lateral cæca, an examination of their contents has led to the suggestion that they secrete a peculiar granular substance, which is thence discharged into the stomach, and "agglutinates the particles of food together," covering them with a membranous integument which serves to protect the delicate coats of the intestine from laceration by the sharp and spiny nature of their food-contents (Tulk, *l.c.* p. 248). Biliary tubes have been described by Treviranus; but it seems probable that the anterior pair of these, at least, are tracheæ connected with the stigmata on each side of the fore margin of the cephalo-thorax. These stigmata were mistaken by Tulk for eyes (*l.c.* p.156).

The *Organs of Respiration* are tracheal. The stigmata in Phalangium (and Gonyleptes ?) are four in number,—two beneath the fore part of the abdomen, situated one at the base of each of the posterior legs, but usually concealed by the coxal joints, and one on each side of the fore margin of the cephalo-thorax; each of the former pair opens into a large obliquely longitudinal tracheal trunk; these two trunks give off various smaller branches and tubes, which convey the air to all parts of the body. With two of these tubes, probably, the cephalic stigmata are connected.

The *Organs of Circulation* are very simple, consisting, in Phalangium, of an elongated dorsal vessel acting as a heart, lying in a groove upon the upper surface of the alimentary canal, and divided into three chambers. Ramifications from this vessel serve to carry the vital fluid to every portion of the body (Tulk). From researches since made by M. Blanchard,[3] it appears that this fluid is recollected from the general circulation into two large lateral vessels (vascular sinuses), from which it is returned by other channels to the dorsal vessel, or heart itself. The structure of the heart consists of a series of transverse, curved, and muscular bands, leaving between them light and membranous intervals (Tulk).

The *Nervous System* of phalangids is very similar in its type to that of some other arachnids. Two large ganglia (cephalic and thoracic) occupy the cephalo-thorax, and from these nerves issue to the various parts, some of them leaving ganglionic enlargements in their course, whence again finer nerves distribute themselves to the adjacent structures. Tulk mentions a striking peculiarity connected with the nervous system of phalangids, which is a power possessed by them to move the nervous centres backwards or forwards at will; this is effected by means of several large transversely striated muscular fasciculi radiating from the sides of the thoracic ganglion, to which they are attached by short tendons (Tulk, *l.c.* 326).

The *Organs of Generation* in the Phalangidea (which are oviparous), are different from all other arachnids in the large external parts connected with them. In the female, the internal parts consist of an ovisac and ovarium (Tulk); whence, by means of the oviduct, the ova are conducted into the ovipositor. This is a long membranous tube; the first or basal part of it is surrounded by annuli or rings of hairs or bristles; towards the extremity it is scaly, and also furnished with some hairs, and the extreme point has two small lateral tufts of hairs. The ovipositor is protruded, at the will of the animal, from the vulva, which is situated at the fore margin of the sternal plate, or else it is, when at rest, withdrawn into its sheath, leaving no outward trace of it visible. In the male, the seminal vessels consist of a cluster of "slightly tortuous cæcal tubes," whence the spermatic fluid is passed by a duct into a penis of enormous length compared to the size of the animal (fig. 12, *d, e, f*). This organ is a slender curved tube, furnished at its extremity with a recurved hook, and contained in a sheath; both the sheath and penis when at rest lie in a longitudinal direction beneath the ventral surface, of the thorax, but can be protruded at will from the external aperture, which is similar, and similarly situated, to that of the female. The form of the penis varies in different species, as also does the ovipositor of the female. The organs of generation, both male and female, of *Phalangium opilio*, are detailed a great length by Tulk, *l.c.* Both the penis and ovipositor may be made to protrude by a slight lateral pressure beneath the fore margin of the sternal plate.

GENERAL OBSERVATIONS.—The Phalangidea have been found in all parts of the world, but though often very numerous in individuals, the number of species as yet discovered is comparatively small. In the British Islands, where about sixteen species have been observed, they are popularly known by the name of "Harvest-men,"[4] probably because most numerous at the time of harvest. They run with great rapidity over and among grass and low herbage, and many live among the leaves and mossy covering of trees, among moss on the ground, heath, and stems of herbage; also under stones, and among rubbish and debris. Their prey is small insects, the young of the true spiders, and some species of Acaridea. The small size of the body, compared with the inordinate length of the legs, in some genera is exceedingly striking. In an undescribed species of Leiobunus, from the Brazils, the length of the body is but a line and a half, while that of

the longest legs exceeds fifty lines; being in the proportion of about 1 to 32. Phalangids part easily with their legs, or with portions of them; and when detached these legs retain the power of motion for a considerable time, due probably to sustained nervous energy. The order may be divided into about four well-marked families.

Fam. I. *Cyphophthalmides.*—Characterised by an oval, flattened body, short legs, with undivided tarsi; falces projecting far in front of the fore part of the caput, and three-jointed (Joseph). Eyes on pedicles, one on each side of the cephalo-thorax near the lateral margin.[1] One genus only, Cyphophthalmus (Joseph), and two species, *C. duricorius* (Joseph), and *C. corsicus* (Simon), have as yet been discovered, both of very small size, and both South European. They have an exceedingly acaridian appearance, and seem evidently to connect the acarids with the more typical Phalangidea. See G. Joseph (*Berl. Ent. Zeitschr*, 1868, pp. 241-250 and 269-272), who speaks of but two tracheal stigmata; probably the thoracic stigmata were overlooked. The form of the maxillæ appears to be peculiar.

Fam. II. *Trogulides.*—Somewhat similar in general appearance to the former family, but differing in the parts of the mouth being concealed beneath a kind of hood, which projects beyond the fore margin of the cephalo-thorax; and in the eyes, which are placed, well separated, in a transverse line at the constriction, where the hood joins the caput. Two genera,[2] Cryptostemma (Guérin) and Trogulus (Walck.), have been characterised; of the former one species only is yet known, *C. Westermanni* (Guer.), Guinea. Of the latter genus the species are few, and little appears to be known of their habits or economy; one only, of small size, *Trogulus Cambridgii* (Westwood[3]), has been found in England (at Bloxworth, among moss, by the Rev. O. P. Cambridge), remarkable from the dense clothing of short squamose hairs on the body, and hooked spine-like bristly hairs on the legs.

Fam. III. *Phalangides* (figs. 10, 11).—Characterised by their small,

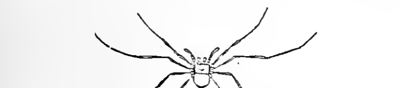

FIG. 10.—*Phalangium copticum*, Savigny. *a*, *a*, falces; *b*, eyes; *c*, cephalo-thorax; *d*, abdomen; *e*, *e*, palpi; *f*, junctional line of cephalo-thorax and abdomen.

round, oblong, or oval body; exceedingly long, slender legs, with multi-articulate tarsi; eyes close together, one on each side of a tuberculous eminence on the vertex of the cephalo-thorax (fig. 12, *a*); the eminence, as well as other parts of the body, often armed with spines. Falces (fig. 13) often of great size and length, the terminal joint articulated sometimes at its end, sometimes further on. Several genera of this family have been characterised, and numerous species recorded, mostly European, but our space will not permit of further details, which may be found in the work of Hermann before noted,

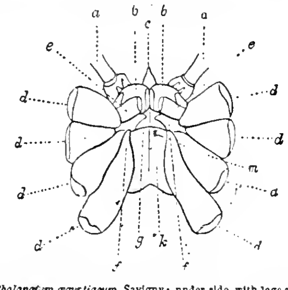

FIG. 11.—*Phalangium ægyptiacum*, Savigny; under side, with legs and palpi truncated, and without abdomen. *a*, *a*, palpi; *b*, *b*, maxillæ; *c*, tongue; *d...d*, first joints of legs; *e*, *e*, *f*, *f*, supernumerary maxillæ, supporting first two pairs of legs, and used in eating (?); *g*, membranous lip (*labium*); *k*, sternal plate (*sternum*); *m*, fore-margin of sternal plate, under which (at *) are sexual organs.

under *Acaridea;* also in those of Latreille, *Sur l'Histoire des Insectes connus sous le nom de Faucheurs* (*Phalangium*) (pub. 1802), and

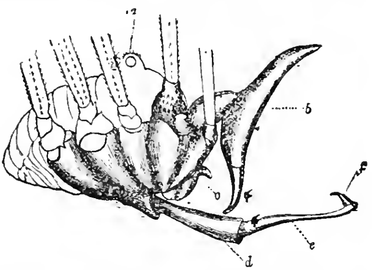

FIG. 12.—Harvest-man (*Phalangium cornutum*, Linn.); profile, with legs and palpi truncated. *a*, eye eminence; *b*, falces; *c*, portion of mouth apparatus; *d*, sheath of penis protruded; *e*, penis; *f*, the glans.

Herbst; in *Natursystem der ungeflügelten Insekten*, 1798-99; P. Gervais, in Walck. *Ins. Apt.*, vol. iii. p. 94; and Koch, in *Die Arachniden*, 1831-1848; and in numerous isolated papers by various later authors. Most of the anatomical details known of the order Phalangidea have been obtained from species of this family.

FIG. 13.—Falces and palpi of *Phalangium copticum*.

Fam. IV. *Gonyleptides.*—This differs from the last in the generally more or less quadrangular form, or roughly diamond shape; the cephalo-thorax is proportionally larger, often appearing almost entirely to overwhelm the abdomen; it is also more spinous and tuberculous; the palpi are longer, some joints often of great strength and length, and armed with strong spines, sometimes assuming, with the strong terminal movable claw, a raptorial appearance. The legs are shorter and stronger, and those of the hinder pair are usually armed with spiny processes, tubercles, and spines; the coxal joints being often inordinately developed, reaching to the extremity of the abdomen, to which, as well as to the cephalo-thorax, they are immovably attached. The tarsi are not multi-articulate. The species are tolerably numerous, and all exotic. Several genera have been characterised, on the species of the chief and typical one of which, *Gonyleptes* (Kirby), a Synonymic List, with descriptions of some new species, has been published by Mr A. G. Butler, in *Ann. and Mag. N. H.*, Feb. 1873, pp. 112, 117, pl. 3., continued in *Jour. Linn. Soc.* 1874, vol. xii. pp. 151-155, pl. 8. Some of the works quoted on Phalangides also treat of this family. H. C. Wood, jun., considers the order generally in *Trans. Amer. Phil. Soc., U.S.*, vol. xiii. pp. 435-442, pl. 24.

[1] Since the above was written, Professor Westwood has founded a new genus—Stylocellus—on *S. sumatranus* (Westw.) *Thesaurus Entomologicus Oxoniensis*, Oxford, 1874, p. 200, plate 37, fig. 7.

[2] Professor Westwood (*l.c.* p. 201) separates Cryptostemma, and (with Cryptocellus, a new genus founded on *C. fœdus*, Amazons, *l.c.* fig. 6) forms a new family CRYPTOSTEMMIDES, between Cyphophthalmides and Trogulides.

[3] *L.c.*, p. 202, fig. 6.

Order IV.—SOLPUGIDEA.

This order constitutes a small but very distinct and remarkable group of tropical and semi-tropical Arachnids. At first sight they remind us a good deal of the true spiders (Araneidea), but their position, when we examine their structural details, seems to be more naturally assigned between the Phalangidea and the next order (Scorpionidea) (figs. 14, 15).

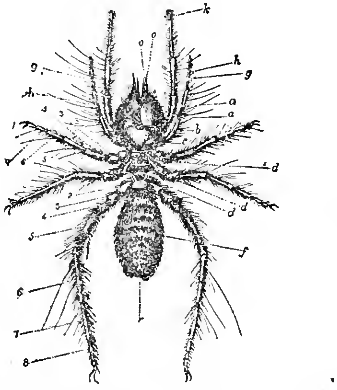

FIG. 14.—*Galeodes araneoides*, Pallas. *a, a,* falces; *b,* eyes; *c,* head; *d, d,* thorax; *f, f,* abdomen; *g, g,* palpi; *h, h,* palpiform legs; *k,* digital joint (capsule); *o, o,* shear-like points of falx; *r,* anus.

EXTERNAL CHARACTERS.—The *body* is elongated and clothed with hairs; it is divided, as in other Arachnids, into two main portions (cephalo-thorax and abdomen), but each of these portions is composed of several segments or articulations. The caput forms the first segment of the cephalo-thorax; and this is followed by three others closely united to each other, and of a somewhat quadrangular form. Close behind each coxal joint of the legs of the second pair is a small transverse slit or stigma leading to tracheæ.

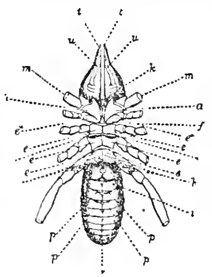

FIG. 15.—Under side of *Galeodes araneoides*, with legs and palpi truncated. *a, a,* maxillæ; *e...e,* basal leg joints; *e* e*,* first joints of first pair of legs; *f* labium; *h, h,* fish-tail appendages; *i,* external orifice of sexual organs; *k,* tongue; *m, m,* palpi; *o, o,* respiratory organs at base of second pair of legs; *p..p,* orifices leading to tracheæ at fore-margins of second and third segments of abdomen; *r,* anus; *t, t,* fixed upper fangs or claws of falces; *u, u,* movable lower ditto.

The *eyes* are two in number, and seated on a tuberculiform eminence on the fore part of the caput; this eminence is furnished with two long slender spines, placed in a transverse line between the eyes, and projecting forwards.

The *legs,* articulated by a fixed joint to the lower surface of the thoracic segments, are long and strong, furnished with hairs (some of which are remarkably long), bristles, and spines, varying in length and strength. The legs of the first pair are palpiform and not used in running, probably having the sole office of feelers. The number of joints of those of the first and second pairs is seven, while those of the third and fourth pairs have eight, an extra joint being inserted between the basal and next adjoining joints; the tarsi of the first pair are simple, or undivided, and terminate with two small curved claws, while those of the other three pairs are often divided into two, three, or more articulations, besides a small terminal or heel joint, from which spring two long curved finger-like claws, each ending with a curved (apparently movable) nail or talon. The number, however, of the tarsal joints appears to differ in some species from others, and even in the different legs of the same species. The legs of the second, third, and fourth pairs belong to the three thoracic segments respectively, while those of the first pair are closely united (and even soldered) by their basal joints to the basal joints of the palpi beneath the caput, thus furnishing an additional reason for supposing them to be more of a palpal than of a crural nature; between the bases of the first pair is a small triangular piece (with its apex directed forwards), unnoticed by authors hitherto (?) and which may be regarded as a rudimentary sternal lip (labium); on the under sides of the three basal joints of each of the fourth pair of legs is a longitudinal row of five curious scale-like or lamelliform appendages, of a subtriangular or somewhat fish-tail form, each articulated to a separate foot-stalk, which is again articulated to the surface of the leg joint; beginning from the basal joint the form of the last two of these appendages differs a little from that of the rest. That these remarkable portions of structure have some special office is scarcely to be doubted, but as yet their part in the animal economy has not even been conjectured. They appear to differ slightly in structure in different genera.

Articulated immediately below the fore-margin of the caput are two enormous, massive *falces,* each consisting of a single joint, and ending with a didactyle claw or pair of toothed jaws, the upper fixed, the lower movable, and articulated horizontally with a vertical movement, closing upon each other like scissors or shears; these falces are projected in a line almost parallel with the caput, and are generally equal in length to the whole of the cephalo-thorax. From the fore part of the upper side of each of the falces are often seen one or two curious elongate styliform appendages varying in size and form; their use, if any, which may be doubted, is unknown, they are probably distinctive of sex, and appear to be characteristic of species. Underneath the caput, and forming the basal joints of two long strong five-jointed palpi, are the *maxillæ;* these are strong, cylindrical, and have a more or less strong blunt-pointed apophysis at the extremity on the inner side. Like similar parts in other Arachnids, these maxillæ, in conjunction with the affixed basal joints of the first pair of legs, form the lower boundaries of the mouth, the labium (mentioned above) being apparently too rudimentary to subserve any practical purpose. The *palpi* are furnished with hairs, spines, and bristles similar to the legs, and the last (digital) joint consists of a kind of capsule containing a peculiar organ, said to be protruded only when the animal is in a state of irritation, the use of which does not appear to be known; doubtless it has some special function beyond that of a mere palpus, and the analogy of the use of the palpi in the males of the Araneidea would lead us to suspect a similar use in the present instance, *i.e.*, as connected in some way with the process of generation. Between and within the maxillæ is a portion of the *mouth organs,* composed of several parts of a peculiar shape, and furnished with two slender feather-like appendages; this is called by Walckenaer the lip (*lèvre*); but its place and office is undoubtedly more that of the tongue (*languette*), though probably in the rudimentary state of the true labium it partly performs the duty of a sternal lip. Dugès and M. Edwards in Cuvier's *Règne Animal* (Arachnides, p. 83), speak of the "labre," but it is evident from their description that a portion of the *languette* is alluded to, not the part mentioned above as representing the labium. The *abdomen* is oblong, oval, or somewhat elliptic in its form, about equally convex above and below, and composed of nine or ten articulations, which decrease in breadth from the fore to the hinder extremity; it is closely united to the cephalothorax throughout its entire breadth. The external orifice leading to the organs of generation is situated at the posterior margin of the first articulation, and besides the two stigmata before alluded to, behind the basal joints of the second pair of legs, there are two other stigmatic openings[1] at the hinder margin of each of the second and third articulations of the abdomen; these stigmata are protected by a kind of comb-like fringe, and the anal orifice consists of a long vertical slit situated at the extremity of the terminal articulation.

INTERNAL STRUCTURE.—The *Muscular System* of Solpugids appears to be very similar to that of other Arachnids; it has been fully displayed by Dr M. Kittary in the work quoted in note, of the present page.

The *Respiratory System* is tracheal and complicated. Five (according to Dr Kittary) openings at the hinder margins of the second, third, and fourth sub-abdominal articulations, lead to the abdominal tracheæ; these consist of three longitudinal parallel tubes, into the outer one of which the short branches from the external openings lead, and with these are connected various other branches supplying air to the different parts of the body. The abdominal tracheæ also lead into those of the cephalo-thorax, which have their outer openings (two in number) behind the basal joints of the second pair of legs. The thoracic tracheæ send branches into the legs, palpi, and falces.

There is probably some variation in different species in the details of their respiratory organs. *Galeodes Araneoides*, for instance, does not appear to have the fifth outward opening in the abdomen (fig. 15).

The *Circulatory System* consists of an elongated dorsal vessel or heart, running from the middle of the cephalothorax backwards through the connection between the thorax and abdomen, but does not reach the hinder extremity of the latter. The thoracic portion is of an oval form, but it contracts in passing into the abdomen, enlarging again gradually as it runs backwards. Dr Kittary does not appear to have traced the various vessels which, no doubt, exist to convey the vital fluid from the heart to the different parts of the body.

The *Organs of Digestion* consist of an elongated stomach in the cephalo-thorax, with lateral cæca; this stomach is continued backwards into the abdomen in the form of a long single intestinal canal, leading into a cloaca at its posterior extremity. A kind of branching network of minute vessels secrete urine, and convey it from the whole abdominal mass by several main branches into the hinder part of the intestinal canal. Beneath the stomach is an organ described as probably the liver, and another answering to the pancreas.

The *Nervous System* is not particularly complicated, but bears great resemblance to that of other Arachnids, especially of the Araneidea. It consists of one large principal ganglion, or united pair of ganglia, from which branch nerves are sent off in all directions to the different parts and extremities of the body; that which runs to the hinder extremity of the abdomen has an enlargement or kind of ganglion in its course.

The *Organs of Generation* are highly developed in the female, consisting of ovaries, and an oviduct leading to the external orifice. The male organs do not appear to be known. The Solpugidea are probably oviparous.[2]

The order Solpugidea comprises a single family, *Galeodides*, divided into five genera, characterised principally according to the number of the subdivisions of the tarsal joints of the second, third, and fourth pairs of legs:—1. *Rhax* (Hermann), the tarsi all one-jointed.[3] 2. *Aellopus* (Koch), tarsi two-jointed; those of the hinder pair destitute of claws (Koch). 3. *Galeodes* (Olivier), tarsi of the second and third pairs two-jointed, and of the fourth pair three-jointed. 4. *Solpuga*, tarsi of the second and third pairs four-jointed, and of the fourth pair seven-jointed. 5. *Gluvia* (Koch), all the tarsi undivided, *i.e.*, consisting of a single long thin joint.

Fifty-two species (of all the genera) have been described. See a recent paper, *List of the Species of Galeodides*, by A. G. Butler; also the older work of Koch, *Die Arachniden*. All the species, though varying considerably in size, are remarkably similar in general form and appearance, and nearly all are of sombre colouring.

GENERAL REMARKS.—The Solpugidea are nocturnal in their habits, living by day secreted under stones, among debris and rubbish, and in old ruined walls and buildings, in dry sandy places; from such retreats they come forth at night, and run with great swiftness. A recent traveller in Palestine relates, that when living in tents on the plains of the Jordan, near Jericho, each night, as nearly as possible between half-past nine and ten o'clock, several Solpugids entered the tent-door, running and racing with great speed over everything—tables, chairs, and beds—just like mad creatures, but apparently with no definite object, perhaps only attracted by the lights burning in the tent. When disturbed in their diurnal hiding-places they showed fight and were extremely pugnacious; but their being venomous is doubtful, though the Arabs seemed to dread them quite as much as they dreaded the true scorpions, which were also numerous under the large stones lying about. Some interesting details of the voracity and habits in confinement of a species of Galeodes, are given by Captain T. Hutton, *Ann. and Mag. N.H.*, 1843, vol. xii. p. 81. Like the Phalangidea, it swallowed the solid parts of insects, and even of a lizard five inches long. Captain H. assumes, as one use at all events, of the palpal organ mentioned above, that it is "a retractile sucker," to enable it to ascend smooth surfaces. This, however, is very questionable.

Order V.—SCORPIONIDEA.

In spite of differences in their internal anatomy, which appear to ally the Pseudo-Scorpionides more to the spiders than to the true scorpions, some leading features of external structure seem to stamp them at a glance as most nearly related to the latter. The impression inevitably created on a comparison of the true and false scorpions is that the latter are little scorpions without tails. Including them, therefore, here in the same ordinal group as the true scorpions, we may shortly characterise the order as follows:—*Body* elongated-oval; cephalo-thorax of one undivided piece, hard, horny, and often tuberculated or granulose, while traces of thoracic segments soldered together are generally more or less perceptible. *Abdomen* united to the cephalothorax throughout its entire breadth, and composed of several segments formed by articulated transverse coriaceous plates on the upper and under sides, united by two lateral cartilaginous membranes. *Falces* didactyle; *palpi* terminating with a didactyle claw or pair of pincers; the coxal joints of the legs, fixed to the lower side of the thoracic segments, form a kind of *sternum;* the sternal plate, properly so-called, being either wanting or very

[1] Dr Kittary in "Anatomische Untersuchung der Gemeinen (*Galeodes araneoides*) und der furchtlosen (*Galeodes intrepida*) Solpuga," *Bull. Mosc.* 1848, No. iv. tab. vi. fig. 2, *b, b, b*, indicates in *G. intrepida* a fifth stigmatic opening at the hinder margin of the fourth abdominal articulation.

[2] A more recent work on Solpugidea than that of Dr M. Kittary, is by L. Dufour, *Mem. Acad. Sc.*, tom. xvii. pp. 338–446, 1862.

[3] According to Koch, and also to Savigny, in his excellent figures. Dufour, who, *l.c.*, says *Rhax* has two-jointed tarsi, evidently had a species of some other genus before him, probably *Aellopus* (Koch), or else reckoned the metatarsus as a part of the tarsus.

rudimentary. *Eyes* various in number, two to twelve. So far the true and false scorpions run together, but when compared more closely, differences, especially of internal structure, appear, which necessitate their subdivision into two groups or sub-orders. Menge and others, on account of these differences, separate the two groups more widely still; but one chief ground of this wider separation, the respiratory system, being in one *tracheal*, in the other (so-called) *pulmonary*, seems scarcely sufficiently well established to warrant it. Not that there is not a wide difference in their respective respiratory systems, but that the whole question of the respiration of Arachnids is hardly so settled as to justify any broad lines of classification being based upon it. In some groups of the first order, Acaridea, and also in the second (Pycnogonidea), no traces have been yet found of a distinct respiratory system, though perhaps this arises from the minuteness of the creatures themselves and the extreme delicacy of the membranous walls of the air-vessels. This latter especially, as has been lately observed in regard to some obscure Myriapodous insects,—*Peripatus* (H. N. Moseley, "Challenger" Expedition, 1874, *Ann. and. Mag. N. H.*, 4 ser. vol. xiv. p. 225),—would make it almost impossible, by any means, to discover these tracheal tubes, when once the air had been expressed from them. Then, again, the so-called pulmonary organs of the true scorpions appear to be, simply, modified tracheæ, entirely destitute of that which specially stamps the true lung, that is, the presence of blood-vessels bringing the vital fluid together, and carrying it through the respiratory organs for aeration. The Araneidea, moreover, have both the tracheal and so-called pulmonary systems combined; and also in this (more extensively worked than any other) order—Araneidea—the researches lately published on their organs of respiration by Philipp Bertkau (*Arch. f. Nat.*, xxxviii. 1872, Heft. 2, pp. 208–233, pl. 7), show how much has yet to be learnt concerning this part of their internal structure. Considering, therefore, that the difference between the respiratory systems of the true and false scorpions should not separate them from the same ordinal group, these with other differences yet appear to necessitate a division within the order. We propose, therefore, to distinguish them under two sub-orders:—1. Pseudo-Scorpiones; 2. Scorpiones.

Sub-Order I.—*Pseudo-Scorpiones.*

These are distinguished from the Scorpiones chiefly by the absence of a tail and by their mode of respiration (figs. 16, 17, 18). The *body* is of an oblong-oval form; the cephalothorax is coriaceous; the abdomen sessile and, generally, composed above of eleven, underneath of ten segmental rings or articulations, usually covered above and below with a double longitudinal series of transverse corneous plates, united laterally by a membrane, the folds of which correspond to the transverse plates. In the second sub-abdominal segmental plate, on each side of the median line, there is (in some species) a small spiracular opening, and in the lateral connecting membrane of the third segment, opposite to the end of the third sub-abdominal plate, on either side, is another similar opening. These four stigmata are the external apertures to the tracheary system (fig. 18); behind and between the two first mentioned stigmata is a spinning organ, furnished with minute tubes for the emission of the silken threads; and close to this spinner, at the fore margin of the first abdominal segment, is the genital aperture.

The *legs* are closely affixed by the coxal joints to the lower side of the cephalo-thorax, and sit closely to each other, having a very small longitudinal space between them analogous to a sternal plate, of which, however, there is not even a rudimentary one, properly so-called. The number of joints in the legs is seven (Menge), but there appears to be a variation in this respect in some species. Each tarsus ends with two curved finger-like claws terminating with a short nail, and beneath them is another claw, modified at its extremity, gradually enlarging into a kind of conical form probably acting as a sucker for the purpose of adhesion to smooth objects (fig. 18, *d*). The tarsal claws spring from a small heel or claw-joint.

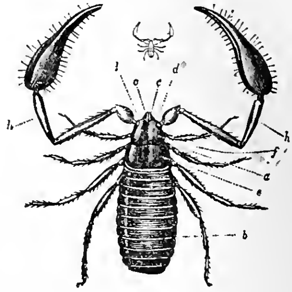

Fig. 16.

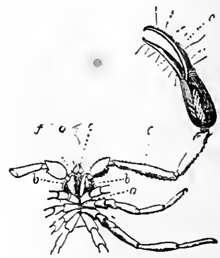

Fig. 17.

FIG. 16.—*Chelifer sesamoides*, Savigny. *a*, cephalo-thorax; *b*, abdomen; *c c*, falces; *d*, *d*, eyes; *e*, hinder segment of cephalo-thorax; *f*, front ditto; *h*, *h*, palpi.

FIG. 17.—The same; portion of under side. *a*, rudimentary sternum; *b*, maxillæ; *c*, palpus; *d*, digital joint; *e*, movable fang; *f*, labium; *o*, *o*, falces.

The *palpi* are five-jointed, long and strong, terminating with a digital joint of large size, more or less bulbous at its base, and drawn out at its extremity into a jaw-like claw, furnished with hairs and bristles, and generally serrated along its inner edge. Against this claw another, articulated to the extremity of the bulbous portion, acts in opposition like the pincers of a crab. Supporting the palpi on either side are the maxillæ, forming the lower side of the mouth, the upper side being formed by two didactyle falces; besides the movable jaw of the falces, there are connected with them some denticulate spines, or other spiny processes and bristles. Within the mouth is a tongue, which also serves as a sternal

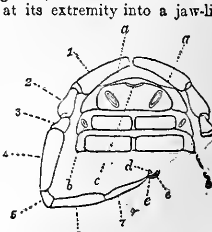

FIG. 18.—*Chelifer cancroides*, Linn.; portion of under side. *a*, *a*, *b*, *b*, orifices of the respiratory organs. *c*, genital aperture; *d*, sucker-like tarsal claw. *e*, *e*, superior tarsal claws.

labium, and differs in its form in different species. The *eyes*, two or four in number, are situated on each side of the fore part of the cephalo-thorax, but there are none in the medial line. In some instances eyes are wanting altogether.

With regard to *internal structure*, the Pseudo-Scorpiones are very similar in their *muscular system* to the spiders (Araneidea) (Menge). The *digestive apparatus* is simple; a large stomachal pouch contracted a little in the middle lies in the thoracic cavity, and from it the alimentary canal runs through to the hinder extremity of the abdomen, with a double crook in the course of its passage; this canal is imbedded on all sides in a mass of substance serving the function of a liver. The external spinning organs have already been mentioned; the internal apparatus resembles that of spiders, consisting of a number of small elongated pear-shaped sacs, communicating outwardly with the spinning tubes.

Nothing certain appears to have been discovered in regard to the *circulatory system* of the pseudo-scorpiones, except that a simple vessel runs along beneath the middle of the abdominal ridge; the vital fluid being found free among all the other organs of the body, so that the air is conveyed to the blood by numerous air-tubes, and not the blood to the air.

The tracheal character of the *respiratory system* has been just mentioned. The spiracular openings vary in number in different species, two or four. From the two hindermost of the abdominal apertures, when four are present, there issue more or less numerous thread-like tubes, which convey the air to the different parts of the abdomen. From each of the two foremost stigmata a main tube runs obliquely through the thoracic region, and from this tube finer ones issue to the rest of the cephalo-thorax and its adjacent parts—legs, palpi, and falces. When two spiracular openings only are present a large tube runs from each forwards into the thorax, and finer ones backwards into the abdominal parts.

The *reproductive organs* are simple. The external parts in both sexes are situated in the second (?) segment beneath the fore part of the abdomen, and consist of two small oval openings close together. Into each of these there opens in the male a curved horn-like sac, with a lateral direction, as well as a smaller longitudinal duct, the latter leading from a common seminal receptacle. In the female a two-branched oviduct leads from the ovaria into the external apertures; the mode of reproduction is oviparous, and the eggs are carried by the female beneath the fore part of the abdomen, somewhat like those of certain of the Araneidea.

General Observations.—The Pseudo-Scorpiones are all of very small size; they do not appear to form more than one family group, *Pseudo-Scorpionides*, of which several genera and numerous species have been described by various authors. They are widely distributed, being found in tropical as well as in temperate climates. Europe possesses many species, and even England has several—these being the sole representatives of the Scorpionidea in this more northern latitude. Their habitat is under stones, beneath the decaying bark of trees, on the damp soil, among moss and herbage; some are found amongst old papers in houses, and in herbaria, and others are said to be parasitic on the common house fly. For more minute details of structure and other particulars, see A. Menge, *Ueber die Scheerespinnen, Chernetidæ*, who separates them from the scorpions under the above name, as a family group, more nearly allied by their internal structure to the true spiders than to the former. Menge gives also a list of works on this sub-order. A paper lately published by Dr Ludwig Koch, at Nuremberg, 1873, pp. 68, describes and gives analytical tables of all the European genera and species at present known.

Sub-Order II.—*Scorpionidea*.

Between the solpugids and the scorpions (figs. 19, 20) the last group (Pseudo-Scorpiones) gives us an evident connecting link.

In the present sub-order, *Scorpionidea*, or true scorpions, the External Structure consists of a more or less elongated oval body, covered with a coriaceous, or hard and horny integument. The cephalo-thorax is tuberculate or granulose, and marked with various seams, or grooves, and ridges, no doubt indicating the union of the caput and thoracic segments. One longitudinal, and, in general, strongly

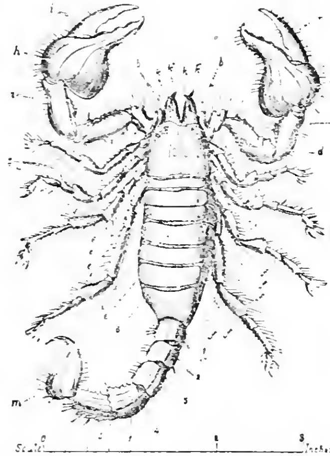

Fig. 19.—Scorpion (*Buthus ...*, Koch). *a, a*, palpi, of which *h, h*, are the digital or fourth joints, and *i, i*, the movable fingers; *b, b*, falces, with two movable fangs, *k, k*, and two fixed ones *k*, k*; *d*, eyes; *e...e*, upper segmental plates of abdomen; *f...f*, articulated cartilaginous membrane, connecting upper and under plates of abdomen; *m*, bulbous sting.

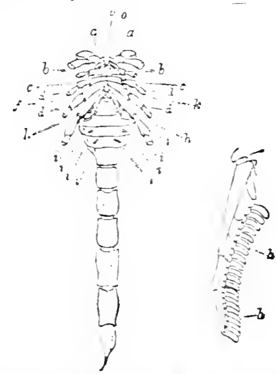

Fig. 20.—*Scorpio Americanus*, Sav., under side, with legs, palpi, and falces truncated: *a, a*, maxillæ; *b, b*, supernumerary or second pair of maxillæ, supporting first pair of legs; *c, c*, third pair of ditto supporting second pair of legs; *d...d*, basal joints of two hinder pairs of legs; *f*, orifice of sexual organs; *h, h*, comb-like appendages (also figured separately, enlarged); *i...i*, eight spiracles leading to breathing organs; *k*, rudimentary sternal plate; *o, o*, portion of third pair of supernumerary maxillæ acting as a sternal labium.

marked groove always divides the *caput* longitudinally, dividing also the tubercle on which the central pair of eyes is placed. This groove possibly represents the union of the two segments of a kind of duplex caput analogous to the duplex generative system noted *postea* (p. 285). The *abdomen* is sessile, *i.e.*, united to the thorax throughout its whole breadth, and composed of twelve segments, of which the five posterior ones form a tail; these latter are segments in the strictest sense, while those of the abdomen proper are, more correctly speaking, articulations covered above and below with transverse horny plates. Articulated to the fifth joint of the tail is a bulb terminating with a sharp curved sting. Poison secreted in the bulb is injected into wounds through two minute perforations near the extremity of the sting. The *legs* are not very robust, nor long, nor very unequal in length; each consists of seven joints, of which the basal ones (coxæ), are fixed to the under side of the cephalo-thorax, and act partly as a sternum; the only portion which can be said to represent a real sternal plate being a very small sub-triangular, or in some genera, quadrangular piece immediately behind the first segment of the abdomen between the extremities of the coxæ of the fourth pair of legs (fig. 20, *k*). These latter are soldered to those of the third pair, the junction being visible as a more or less distinct groove. The coxæ of the first and second pairs have angular pieces attached to them, used in manducation, and hence called supernumerary maxillæ (fig. 20, *o*, *o*, *b*, *b*); but while the pieces of the first pair might perhaps be so named, those of the second pair, closing together as they do on their inner margins, rather form a kind of sub-triangular sternal appendage representing the *labium*, of which there is none properly so-called. Each tarsus ends with two rather long curved superior, and one short straight tooth-like inferior, claws. The first and second segments of the abdomen underneath are almost rudimentary, between them and the anterior edge of the first segment is situated the external aperture to the organs of generation, the horny plate protecting it being divided longitudinally by a more or less distinct groove. From the second segment, and articulated to it, spring two very conspicuous, curious, comb-like appendages (fig. 20, *h*, *h*), composed of a longitudinal shaft of several distinct joints, with a number of slightly curved, bluntish tooth-like processes, fitting closely together, and articulated to their hinder edge, nearly at right angles, like the teeth of a comb. The shafts and teeth of these appendages vary in the details of their form and structure; their use has not yet been certainly ascertained, but their position points to some connection with the process of generation, which is also the opinion of L. Dufour and others; while they have also been thought to be intended to brush away obstructions from the spiracular orifices and other parts; but as in no case are they long enough to reach more than the first pair (out of four) of these orifices, and every consideration of structure is against their being used to clean other parts, this conjectured use is scarcely probable. The spiracular orifices are situated on the under side of the abdomen in four pairs—one pair in a transverse line on each of the third, fourth, fifth, and sixth segmental plates, and are in general easily seen.

The *eyes* (six, eight, ten, or twelve in number) are placed on the fore part and upper side of the cephalo-thorax,—two, generally large ones, in a transverse line near the middle of the upper part of the caput, the rest (much smaller and varying in size in different genera and species) in two symmetrical groups, one on each side near its fore corners. The *falces* form, as in other Arachnids, the upper side of the mouth; they are strong, cylindrical, and didactyle, the outer jaw-like terminal claw being articulated in opposition to the inner one; both are toothed, the denticulations varying in number size and form. Below the falces (and forming with the before-mentioned coxal appendages a complete lower boundary to the mouth) are two strong *maxillæ*, from each of which (as a basal joint) springs a long strong *palpus* of four joints, the last (digital) joint being more or less bulbiform at its base and didactyle at its extremity. The outer claw is movable and (like the fixed one) serrate or denticulate on its inner edge. The size and form of this didactyle joint vary in different species and genera; in some it is of enormous size, and its denticulations very strong, while in others it is scarcely larger than the joint which precedes it. It is the possession, the position, and the office of the exact counterpart of this palpus, which, apart from other considerations, so plainly stamp the affinity of the two sub-orders of the Scorpionidea, in spite of the differences of their respective internal anatomy. Within the mouth parts above noted is a pointed tongue (*languette*) tipped with hairs.

INTERNAL STRUCTURE.—The *Muscular System* of scorpions is similar to that of other Arachnids. It is well detailed by L. Dufour (*Savants étrangers*, xiv. pp. 609–611), who divides the muscles into *thoracic*, *abdominal*, and *caudal;* those of the abdomen being also subdivided into *tegumentary*, *perforant*, and *cardiac*.

The *Organs of Digestion* consist of a straight narrow intestine, with little or no dilatation, running from the mouth to the anus, which has its external opening at the lower extremity of the fifth or last segment of the tail. At the junction of the stomachal and intestinal portions the biliary vessels are inserted, and from each side of the former (stomachal part) there issue five narrow cæca running into a mass of fatty matter on either side.

The *Respiratory Organs*, or pulmo-branchiæ, have their external orifices or stigmata (as before mentioned) in four pairs on the ventral surface of the abdomen; the pulmo-branchiæ, of which one is connected with each stigmatic opening, are hollow sacs, the walls of which are folded into delicate laminæ, each being duplex,[1] and all lying one upon another like the leaves of a book; the air is admitted to these through the external openings, which are closed by movable horny lips as in insects. (Jones, *Animal Kingdom*, 2d ed., 416.) According, however, to L. Dufour (*l.c.*, p. 617), the lips of the stigmata are immovable, and have a varied direction in different species. The air is admitted to the pulmo-branchiæ by the action of a linear opening in a supple membrane or diaphragm within the space between the lips and the laminæ (L. Dufour, *l.c.*)

Organs of Circulation.—These, according to Newport (*Philos. Trans.* 1843, pp. 286–298), consist of an elongated, dorsal muscular vessel (or heart) divided into eight chambers, separated from each other by valves, and with auricular openings or valvular orifices, at the division of each chamber, on its dorsal surface. From both sides, and at each end of the dorsal vessel, arteries convey the vital fluid for distribution to different parts of the body.

This dorsal vessel apparently acts in a manner analogous to that of the heart in vertebrate animals. The vital fluid is conveyed back to the "heart" from the pulmo-branchiæ, where it has been oxygenated by means of a great number of slender canals, formed by the collection together of vessels that have their origin at the hinder part of the inner side of the pulmo-branchiæ. These canals pass round the sides of the body in the hinder part of each segment, and pour their contents into the dorsal vessel through the valvular orifices above mentioned. The conveyance of the fluid from the general circulation to the pulmo-branchiæ is effected by means of an intricate system of anastomosing pulmonic and capillary vessels, situated chiefly below the nervous chord on the ventral surface of the body.

---

[1] L. Dufour, *l.c.*

From the above L. Dufour (*l.c.*) dissents. According to his researches, which appear to have been pursued under the great advantage of having fresh as well as living examples to observe and dissect, the heart (or dorsal vessel) is not divided into chambers at all; its chambered appearance, which misled Newport and others, arising from inevitable changes in the form of the organ after death, and long immersion in spirit of wine. Dufour gives very exact figures and descriptions of these changes. According to him the heart is a simple, undivided vessel running throughout the whole body, only narrowing at the fore part of the caput, and in its passages through the tail; and from this tube various lateral veins and arteries issue, those from the hinder or tail portion being profusely branched. He dissents entirely from Newport, Blanchard, and others, with regard to the mode above mentioned in which the vital fluid is conveyed to and from the pulmo-branchiæ, but he confesses that he has not been able to find out how it is actually effected, though he believes that the pulmo-branchial laminæ are permeated by vascular ramifications spread out over every one of their leaves, and that in these ramifications the fluid receives the benefit of the air admitted to the laminæ. Siebold, however, says that no traces of blood-vessels have been found in the pulmonary lamellæ of another order, Araneidea; and it is hard to believe but that, if such details as those given by Newport in regard to the scorpion actually existed, Dufour, with the advantage of fresh examples to dissect, should have been unable to discover it. On the whole, it seems too soon, even yet, to dogmatise on the position of the scorpions from their respiratory and circulatory systems. That they have these two systems, the first by means of a dorsal vessel, with lateral branches, the latter by a kind of pouch containing a modification of tracheæ, is certain; and that their system is different from that of some other groups is also certain, but in the absence of a more perfect knowledge of the real nature of the difference, its true value cannot well be yet ascertained.

Nervous System.—A longitudinal row of nine—according to Newport, eight—ganglia, connected by a double nervous chord, is situated in the median line of the body, below the intestinal canal. The first ganglion consists of two lobes, the upper one of which, occupying a position somewhat analogous to that of the brain in the Vertebrata, is so called (*cerveau*) by Dufour. From these lobes the optic and other nerves issue, some of them being connected with the various parts of the mouth and the legs. A nervous-collar, according to some authors, surrounds the œsophagus. Dufour, however, disputes the existence of this collar, and explains how the idea of it arose, *l.c.*, pp. 556, 557. Of the remaining ganglia four are, according to Dufour, situated in the abdomen, and from these four there spring on each side and underneath, branching nerves, which run to each of the pulmo-branchiæ respectively and their adjacent parts, as well as to the viscera and tissues of the abdomen. The first abdominal ganglion is in close connection with the large thoracic one, and is in some instances so little developed that Newport and others, overlooking it, derived the nerves running to the first pair of pulmo-branchiæ from the thoracic ganglion itself, and thence allowed but three to the abdomen.

The caudal ganglia, four in number, do not correspond to the number of segments, which are five, or counting the terminal bulb, six. From each caudal ganglion two lateral nerves only issue, except from the last, whence there issue three pairs; the extra ones, running back, and branching out into the muscles of the poison bulb, doubtless add greatly to its sensibility and irritability.

The *Organs of Reproduction* occupy, both externally and internally, a similar position in both sexes. The external aperture is duplex, situated between the first and second segments of the abdomen, in front of and, in a manner, between the comb-like appendages, and covered by an operculum. Internally those of the male consist of a duplex set of vessels for the elaboration, collection, and conveyance of the seminal fluid to the external orifices, each orifice having its own set. The vessels, answering to testes, in which the seminal fluid is secreted, consist each of a tube forming three large quadrilateral, flexuose, and free, anastomosing meshes placed longitudinally; those of one set sometimes communicating with the other at the lower mesh by a short, strong connecting tube. According to Treviranus the three meshes on either side anastomose with each other, having, in fact, a common connection throughout, but this L. Dufour considers to be an abnormal case; the vessels for the collection of the seminal fluid, *vesiculæ seminales*, are three for each set, and all open into the channel of emission; this is produced backwards in the form of a long, fusiform, sheath-like channel, lying along the flanks of the abdominal cavity, and attenuated at both extremities; within this channel is another slender, corneous sheath-like organ, prolonged to the genital aperture, where it is exceedingly fine. This is "le fourreau et l'armure de la verge" (Dufour), and within it is the intromittent organ itself, having a whitish cartilaginous, thread-like appearance. No recorded observations have yet decided the mode in which these parts of generation are used: the Scorpionides being nocturnal in their habits makes such observations very difficult, but all analogy is in favour of copulation by the exsertion and introduction of the thread-like organs above described into the female parts of generation. These consist of two ovaria, each composed of a membranous tube, forming four large quadrilateral meshes in a longitudinal line on each side, anastomosing with each other and with those of the other side; each of these ovaria ends in a simple oviduct (sometimes with, sometimes without ovisacs) leading to the vulva or external orifice. The general similarity of these female organs with those of the male is at once apparent. A curious point noticeable in these parts in the Scorpionides is their *duplex* character, and hence the question as to their mode of operation becomes of greater interest. It is remarkable that the only other Arachnids in which an intromittent organ is as yet known are among the Phalangides, a group widely separated from the Scorpionides in other characteristic details, though approaching much nearer to the pseudo-scorpions. Scorpions are ovo-viviparous, and, according to Dufour (*l.c.*), their period of gestation is of great length, extending even to fifteen or sixteen months; but for five of these months, which occur in the winter season, Dufour concludes, from frequent observations, that the whole genital apparatus is, like the animal itself, in a dormant state, and that therefore no progress in the development of the ova takes place during this period. On the very important branch of this subject—the *embryology of the scorpion*—reference only can be made to the works of Heinrich Rathke, *Reisebemerkungen aus Taurien* (contained also in Burdach's *Physiology*, Bd. ii. p. 242, *et seq.*) and to that of Dr Elias Metschnikoff, "Embryologie des Scorpions," *Z. Wiss. Zool.*, Bd. xxi. pp. 204–232, taf. xiv.–xvii.; also separate, Leipzig, 1870.

General Observations.—The sub-order Scorpiones forms a remarkably homogeneous group. It has been divided, however, into several families by Koch (*Die Arachn.*); and various genera, based principally on the number and distribution of the eyes, the form of the fore margin of the cephalo-thorax, and the structure of the comb like appendages attached to the under side of the abdomen, have been characterised. The species are tolerably numerous, but the whole group greatly needs revision, both in respect to its family and generic divisions, as well as in regard to the identification and determination of the species. Those found in Europe are of comparatively small dimensions, and are confined to the southern parts of the Continent; the majority are tropical, attaining their greatest size—nine or ten inches in length—in Central Africa and South America. They are nocturnal in their habits, living by day underneath stones, behind the loose bark of trees, among the ruins and debris of old walls and buildings, and preying upon insects and other Arachnida: they are said to be very partial to the eggs of spiders and insects. It does not appear that they are able to inflict any great injury with the, often formidable looking, crab-like claw with which their palpi terminate, though they can gripe and hold on firmly with them. The wound inflicted by the sting at the end of the tail is certainly more or less venomous; the amount of venom is probably dependent on the age of the scorpion, and the season of the year; and the effect of the sting is no doubt dependent upon the state of health, constitution, or predisposition of the person injured. Experiments, tried by Maupertuis, upon poultry and dogs stung by exasperated scorpions, resulted in their almost entire immunity from bad effects, while in Redi's experiments, the sting proved fatal in some instances to pigeons. These experiments were tried with European species of scorpion, which would probably be less venomous than those living in tropical countries. For a recent memoir on the poison of the scorpion, and the mode in which it acts, see Dr Jousset, *Ann. Ent. Soc. France*, 1872, p. 151; also *Comptes Rendus*, 1870, pp. 407–411. According to Jousset, the venom acts directly upon the red globules of blood, paralysing them, so that becoming agglutinated together, they obstruct the entrance to the capillaries and stop circulation. The peasant inhabitants of Tuscany are said to handle scorpions without fear; but this may be chiefly from a skilful mode of handling them. A scorpion does not appear to be able to move its tail or its sting in a lateral direction, nor does it strike downwards. The present writer has seen natives of Egypt handling large, and it is believed very deadly ones with impunity, but then they always held them tightly by the last joint of the tail. It was a common practice so to catch these creatures, and after breaking off the tip of the sting, to let them loose again; but this infliction generally appeared to produce a kind of paralysis of the whole tail, and probably the poor animal would soon die.

Though the well-known tale of the scorpion, when surrounded by fire, stinging itself to death, has been perpetually repeated, and has even been related to the present writer with some very minute and extraordinary details, it must be held to be merely a "traveller's story." Cross-examination, in the special instance noted, very much nettled the narrator at the incredulity which led to it, but it threw more than a doubt over the conclusiveness of the experiment narrated. Probably in some instances the poor scorpion has been burnt to death; and the well-known habit of these creatures, to raise the tail over the back and recurve it so that the extremity touches the fore part of the cephalo-thorax, has led to the idea that it was stinging itself. Perhaps, under the pain of scorching, there may have been convulsive efforts and movements of the highly nervous and sensitive tail in this position, and the point of the sting may even have been inserted between the articulation of the cephalo-thorax and abdomen; and what more would be wanting to make a wonder-loving traveller believe that it had really committed suicide? The progress of scorpions is neither rapid nor graceful; they are unable to run without elevating the tail to an erect position, which seems to be necessary to enable them to preserve their balance.

CLASSIFICATION OF THE SCORPIONES.—The following is Koch's systematic division of the scorpions.[1]

Order SCORPIONES.

Fam. I. With six eyes, *Scorpionides.*—One genus only, *Scorpius* (Ehrb.)

Fam. II. Eight eyes, *Buthides*.—Five genera: *Buthus* (Leach); *Opistophthalmus* (Koch); *Brotheas* (*Id.*); *Telegonus* (*Id.*); and *Ischnurus* (*Id.*)

Fam. III. Ten eyes, *Centrurides.*—Two genera: *Centrurus* (Ehrb.); and *Vaejovis* (Koch).

Fam. IV. Twelve eyes, *Androctonides*.—Three genera: *Androctonus* (Ehrb.); *Tithyus* (Koch); and *Lychas* (*Id.*)

One hundred and twenty two species, distributed variously among the above eleven genera, have been described by Koch (*Die Arachn.*); but many others also have since been added to these, in isolated papers by other authors. For another systematic arrangement, as well as on the group generally, with descriptions of seventy-eight species, see Walckenaer, *Ins. Apt.*, iii. pp. 14–75, where other works are also referred to. Scorpions have been found in a fossil state, as well as in amber, in which substance a species of Tithyus (*T. eogenus*) has been described by Menge.

[1] L. Koch, *Uebersicht des Arachniden Systems*, Nuremberg, 1850, pp. 86–92.

Order VI.—THELYPHONIDEA.

The last group, Scorpiones, seems to be the culminating point of the Arachnids in a certain plane, and it presents the arachnidous type in its highest and most complex state of development. The group now to be considered gradually lowers, so to speak, this type again through its three well-marked families, to the last order Araneidea.

As has been before observed, there is seldom or never in nature exactly the same hiatus between one group and another, as there may be between either of them and others; or, in other words, some groups are far more nearly allied to the one next to it than others are to that next to them, although, perhaps, all of those groups bear the same apparent value in a systematic arrangement. Thus, for instance, the groups A, B, C, D may all be equal in a systematic arrangement, and yet A and B may be far more nearly allied than B and C; or again, C and D may be more closely united than either B and C or A and B. So the two orders of Arachnids—Scorpionidea and Thelyphonidea—are certainly far more nearly allied to each other than, for instance, the Solpugidea and Scorpionidea, or the Thelyphonidea and Araneidea are to each other respectively. So obvious is the affinity of the family Thelyphonides of the present order to the Scorpiones, that Walckenaer and others have included them in the same order, making a separate order of its other family, Phrynides; but the latter family certainly seems nearer to Thelyphonides than even the Thelyphonides to the Scorpiones; and so, while the Thelyphonides and the Phrynides must go together, these last could scarcely with any propriety be included in the same order as the scorpions. This will, we think, be evident when we consider presently their structural characters. From these and other considerations, it has therefore been thought best to separate the Thelyphonides from the Scorpionides, and include them in another order with Phrynides.

In the order Thelyphonidea, the *cephalo-thorax* is similar in the general nature and condition of its integument to that of the scorpions, being hard, granulose, and sometimes tubercular, bearing also visible traces of its soldered segments.

The *abdomen* is segmented, and united to the cephalo-thorax by a pedicle of greater or less strength, but never, as in the Scorpiones, throughout its entire breadth; it terminates in one family (Thelyphonides) with three post-abdominal segments, to which is attached a long multi-articulate setiform tail; in another (Tartarides) with a short tail of different form according to the species; and in the third family (Phrynides) the abdomen terminates with a simple button-like segment.

The *legs* of the first pair are much longer than the rest (in the Phrynides of most inordinate length) and antenniform; the tarsi, and generally the metatarsi, multi-articulate, ending without any terminal claw; the legs of the other three pairs are seven-jointed, with the last, or tarsal joint, subdivided.

The *eyes* when present (as in two families), are eight in number, placed on the fore part of the cephalo-thorax in three groups, and forming a triangle with the apex (more or less acute) directed forwards; the base of the triangle is formed by two lateral groups, each of three contiguous eyes; the apex by the third group of two eyes near together, but not generally contiguous to each other.

The *falces* are monodactylous, or terminating with a simple movable fang. The *palpi* are four-jointed, monodactylous, or rather didactyle in a modified form. The *sternum* is more developed than in the scorpions, but not so fully as in the next order, Araneidea. The *labium* is either entirely wanting or very rudimentary in one family, in another fairly developed, and in another altogether absent. In any case, it is probably of small economic importance compared to the labium in the Araneidea.

Such knowledge as is at present attainable in regard to the internal anatomy of this order will be noted in the separate descriptions of each family. These families are three in number,—*Thelyphonides*, *Tartarides*, and *Phrynides*,—and being very distinct, it will be well to give a short diagnosis of each.

Family I.—*Thelyphonides.*

EXTERNAL STRUCTURE (figs. 21, 22).—The *cephalo-thorax* is sometimes of a tolerably regular oval form, more or less

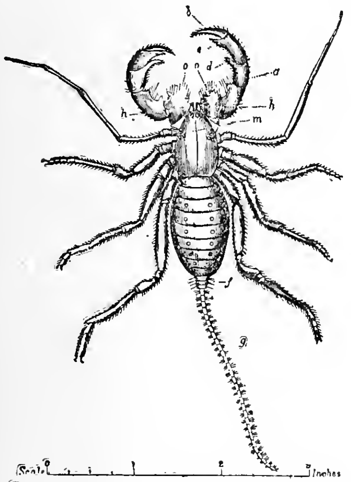

FIG. 21.—*Thelyphonus giganteus*, Koch. *a*, palpus; *b*, movable fang or claw, forming with *c*, claw on fourth joint, a *didactyle* claw; *d*, claw on third joint; *f*, segmental elongation of abdomen, supporting tail; *g*, tail; *h*, *h*, falces; *m*, eyes; *o*, *o*, first palpal joint, with characteristic denticulations.

blunt-pointed before, but often it is of an oblong quadrate shape, also pointed in front, and making not only the hinder part but also the fore part somewhat angular,—the latter having two obtuse lateral angles, and one acute and apical; it is of a flattened form, and destitute of hairs and spines, but is generally granulose, and sometimes covered with more marked, but still minute, tubercles. Marks of segmental soldering are visible, as also a longitudinal groove in the medial line of the caput, similar to, but less marked than, that noted in regard to the scorpions. Beneath the cephalo-thorax are two pieces, which may be regarded as small sternal plates, perhaps the terminal remains representing the complete sternum of the Araneidea, or anticipating its complete form in that order. One of these sternal plates is of a somewhat triangular form, and has its longest or apical angle directed backwards between the basal joints of the first two pairs of legs; the other more heart-shaped, and with the apical angle reversed, is situated between the basal joints of the legs of the fourth pair. In some species a minute corneous patch may be seen between the coxæ, or basal joints, of the third pair of legs, affording still further evidence of the remains of a sternal plate. At the centre of the fore margin of the foremost of these sternal plates is a small point which seems to represent the labium. Beneath the fore part of the cephalo-thorax are two not very powerful *falces*, terminating with a long, powerful, movable, curved fang, somewhat resembling what we find in the Araneidea, and hinting at a transition to that order from the didactyle falces of the Scorpiones. Beneath, and opposed to, this fang is a fixed tooth-like claw; these parts of the mouth are thickly clothed and fringed with hairs. Immediately in front of the fore sternal plate, beneath the anterior part of the cephalo-thorax, are articulated two enormous *maxillæ* of a subtriangular form, the apex being at the articulated part, and the inner basal angle prolonged into a larger or smaller tapering, pointed apophysis, which is now and then denticulate. From the extremity of each of the maxillæ springs a proportionately strong and massive four-jointed *palpus*, powerfully armed with spines, denticulations, and claw-like projections; the inner extremity of the last, or digital, joint terminates like the radial (or the joint next before it), with a strong, claw-like, sharp-pointed projection, in imperfect opposition to which there is a stronger movable claw, of the same nature, articulated to the outer extremity; the fixed claw of the digital joint, with the joint itself, appears capable of being opposed at will to the fixed claw of the radial joint, thus giving the palpi a duplex kind of didactyle claw,—didactyle, that is, in a modified sense, differing as it does considerably from the terminal claw of the scorpion's palpus, which is more properly spoken of as didactyle. The movable finger of this claw would, perhaps, be more correctly reckoned as a *substantive joint*, terminating with a more or less sharp corneous nail; and this joint, opposed to a pointed apophysis of the one to which it is articulated, forms the so-called *didactyle* claw; in fact, the terminal palpal claw of the Scorpiones (including the Pseudo-Scorpiones) as well as that of the Phalangidea, appears to be similarly constructed. In the present family, however, the basal portion of the joint, bearing the fixed claw, being far less developed (seldom stronger or more bulbous than the other joints), and the two fingers being always of unequal length, the didactyle nature of the whole is less real, and less apparent; while in the scorpions its bulbous form is generally apparent, and often inordinate, the equal length of the two fingers and their evidently purposed opposition to each other making the claw, in the fullest sense, didactyle.

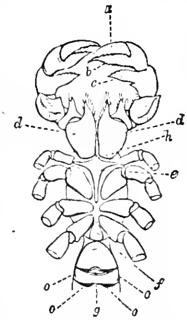

FIG. 22.—*Thelyphonus* —— ? portion of under side. *a*, movable claw of palpus *b*, fixed ditto; *c*, claw on third palps joint; *d*, *d*, maxillæ supporting palpi *e*, *f*, sternal plates; *g*, orifice of sexual organs; *h*, place of labium; *o*...*o* orifices of respiratory organs.

If this view (that the movable finger of this claw is a substantive joint) be correct, the palpi in the present order, as well as in the orders Phalangidea and Scorpionidea, must be considered to have five instead of four joints, thus bringing them to an equality in this respect with the

Araneidea. The palpi in the third family of this order—Phrynides—bear out this idea strongly.

The *legs* are long, slender, and seven-jointed, except those of the first pair, which have but six, the genual, or fourth, joint being absent. The tarsi of the first pair are divided into eight short articulations, while those of the rest have but three. There is probably some variation in the number of these articulations in different species, since Walckenaer describes the tarsi of the three hinder pairs as *five*-jointed; the first pair are far more slender than the rest, palpiform, and without any terminal claw; they appear, as it were, to be thrust out of their position by the great size of the maxillæ, and their basal joints seem to be jammed in over those of the second pair. The tarsi of the three hinder pairs terminate with three claws, of which those of the superior pair are the strongest and curved.

The *abdomen* is of a long-oval form, composed of nine quasi segments, formed by a covering, both above and below, of so many transverse articulated corneous plates; while the cartilaginous membrane on each side, between the lateral margins of the upper and lower plates, is continuous, not folded or articulate as in the Scorpionidea. This is a point to be noted, as it marks a transition to the abdominal type of the Araneidea. The first plate on the upper side forms a protective covering to the pedicle by which the abdomen is united to the cephalo-thorax, and makes the pedicle look broader than it really is. There is a double longitudinal row of impressed circular spots on the upper side, two (in a transverse line) on each corneous plate, except the first and last; these impressed spots are perhaps points of attachment for muscular fibres.

Beneath the abdomen, on the fourth and three following segmental plates, are eight stigmata in as many largish, shallow, circular impressions; they are, however, imperforate, and are probably, like those mentioned above, points for the attachment of muscles. The spiracular stigmata are four in number, two being placed beneath the hinder margin of each of the first and second sub-abdominal plates, one on each side of the median line; the genital aperture is under the hinder margin of the first plate, between the first two spiracular openings. Joined to the posterior extremity of the abdomen are three small cylindrical, post-abdominal segments, to which is attached a long setiform tail, variable in length, composed of a number of small articulations, and, like the legs and palpi, sparingly furnished with hairs; at the extremity of the third post-abdominal segment, beneath the tail, is the anal opening.

The *eyes* are eight in number: two placed transversely, near to each other, on the fore margin of the caput in the medial line, and three others in a triangular group on each side at its lateral angles, just above the insertion of the legs of the first pair

With regard to the INTERNAL STRUCTURE of the Thelyphorids but little appears to have been ascertained. The respiration is pulmo-branchial; the spiracular apertures being, as above stated, four in number, and situated in the position already mentioned Their mode of reproduction is probably like that of the scorpions, ovo-viviparous, but this is conjecture only

GENERAL OBSERVATIONS.—The family Thelyphonides is exceedingly homogeneous, and comprises but a single genus, *Thelyphonus* (Latr), of which twenty-nine species only have been recorded and described,—twenty-six in one of the latest works upon them, by A. G. Butler, *Ann. and Mag. N. H* 1872, vol. x. pp. 200-206, and *Cistula Entomologica*, 1873, part vi. pp. 129–132; and three others in a still more recent paper by the late Dr Stoliczka, *Journ. As. Soc. Beng*, part ii. No. 2, pl. xii.

All the species of this small but remarkable group are confined to the tropical regions of Asia, America, and Australasia, no species having yet been recorded from Africa. In size they vary from rather more than half an inch to 2 or 3 inches in length. Among other characters useful in the identification of the species, are the number and differential development of the various processes and denticulations of the palpal joints. Of their habits little is known, and much of that little is of a very recent date. Dr Stoliczka (*l.c.*) gives a short account of them, from which it appears that they are nocturnal or crepuscular, living by day in damp places under the bark of old trees; when disturbed they hold up the palpi, as if for defence, and beat a rapid retreat, with the tail in an erect position. In this position of the tail we see a curious relationship to the scorpions, but apparently without the same necessity, in the present instance, for such a position. They lie still when uncovered, evidently simulating (though of course unconsciously) a fragment of old bark or fungus. The first pair of legs act more as feelers than as organs of locomotion. In the presence of a sternal plate, the mode in which the abdomen is united to the cephalo-thorax, and the structure of the falces, Thelyphonids approach nearer than the scorpions to the structure of the true spiders, and, as we shall see, the family Phrynides is a transitional group bridging over some part of the gap between the two, while in the massive palpi (though imperfectly didactyle), and in some other respects, they show an unmistakable alliance to the scorpions.

Family II.—*Tartarides.*

This family is nearly allied to the former—Thelyphonides—but has a more elongated form. The *cephalothorax* is beak-like in front, and is also divided into two parts or segments; the first comprises the caput, and the coalesced thoracic segments belonging to the first two pairs of legs; the hinder part is the smallest, and comprises the second thoracic segments belonging to the third and fourth pairs, but no grooves or indentations mark the union of the segments, its surface being smooth and glossy. The *abdomen* is united to the cephalo-thorax by a stout pedicle, and is covered above and below, as in Thelyphonides, with eight or nine transverse, corneous, articulated plates, the upper series separated from the lower by a narrow divisional space, covered with a continuous cartilaginous integument. Beneath the fore part, at the hinder margin of the first sub-abdominal segment, a line-like fissure in the median line probably represents the opening to the reproductive organs; near the fore margin of each of the fourth, fifth, and sixth plates, in a transverse line, are two small elongated stigmata, thought at first to belong to the respiratory apparatus, but further examination seems to prove them to be, like the eight analogous stigmata in Thelyphonides, imperforate, and probably due to the same cause conjectured in regard to them. Two (or four) narrow slits, placed two and two symmetrically on each side of the genital aperture at the fore margin of the first and second segments, but very difficult to be correctly ascertained, are probably the external openings to the respiratory organs; these points, however, can hardly yet be said to be satisfactorily determined. Two or three very narrow corneous rings, or post-abdominal articulations, support a caudal appendage, either slender, cylindrical, and bi-articulate, or of a largish, peculiar, sub-triangular form, articulated to a small foot-stalk. *Eyes* none, no traces even of eyes being visible. The *falces* are strong, of a flattened cylindrical form, deeper than broad, projecting in the plane of the cephalo-thorax, and terminating with a sharp, curved, movable fang at their upper extremity, the lower extremity being rather pointedly prominent.

The *palpi* are very strong, five-jointed, and each issues from a long, strong, nearly cylindrical basal joint or *maxilla*, the inner fore corner of which is prolonged into a sharp, strong point; the other joints are armed variously with teeth, and the final, or digital, joint in one species has a longish, but not very strong, spine beneath it, terminating with a small, apparently movable, curved claw. In these palpi we see a marked transition from the more apparent didactyle nature of those of Thelyphonides to those of the Phrynides, removing them further than the former, in this respect, from the Scorpiones.

The *legs* appear very similar to those of Thelyphonus; they are seven-jointed; those of the first pair are slender and evidently palpiform; their tarsi are composed each of several (apparently ten) minute articulations, and devoid of terminal claws. Those of the other three pairs are apparently inarticulate, and each ends with three simple curved claws, of which the inferior one is the smallest and most sharply bent; the femora of these three pairs are all strong, those of the fourth pair inordinately so. The *sternal plates* are very similar to those of Thelyphonus, but the hinder one is not so much developed, and the central corneous spot is not visible.

This family, of small but exceedingly interesting blind Arachnids, contains but one at present known genus—*Nyctalops* (Cambridge), and two species—*N. crassicaudata* (Id.) and *N. tenuicaudata* (Id.); both are of a uniform pale yellow-brown colour, differing from each other, among other characters, in the markedly different form of the tail; the length of the largest (probably, but not certainly ascertained to be, in the adult state) is but 2½ lines. They are found under decayed leaves in Ceylon; but nothing is yet known of their habits, nor of their internal structure and anatomy; analogy, however, points to a similarity in this latter respect to Thelyphonus.

Family III.—*Phrynides.*

This is also a remarkably homogeneous family, and although, undoubtedly, a near ally of the Thelyphonides, yet in its form it presents many typical characters of the Araneidea (figs. 23, 24, 25).

With respect to EXTERNAL STRUCTURE, the *body* is short and broad instead of elongated, as in Thelyphonus and Nyctalops. The *cephalo-thorax* is flattened, of a round oval form, hollowed on the hinder margin, and often of a short heart or kidney shape; its integument is hard, horny, granulose, and often tuberculose; near the centre is a deep fovea, or pit-like indentation, from which other grooves and indentations radiate, showing the, now soldered up, junctional lines of the caput and thorax, and thoracic segments. In these characters of the cephalo-thorax the affinity of Phrynid_ to the Araneidea is very plainly indicated, as it is also in the eternal plate, around which the legs are articulated.

The *falces* are strong and somewhat cylindrical in form. They project in a line parallel to that of the cephalo-thorax, and each terminates with a strong curved denticulated fang, which is articulated to its upper extremity. The falces are toothed also on their under sides; the denticulations of the falces and their fangs differ a good deal in different species, and form one of the best and most tangible characters for the determination of the species (see a paper on "Phrynus," by A. G. Butler, in *Ann. and Mag. N. H.*, Aug. 1873, pp. 117-125, pls. 6, 7). In the usual position are two strong divergent *maxillæ*, each with a broad obtusely rounded apophysis at the fore extremity on the inner side; from the extremity of each maxilla springs a long, strong *palpus*, in some species of great length, consisting of four or (reckoning the large terminal movable claw as a substantive joint) five joints. This palpus is armed variously with tubercles, spines, and denticulations, especially on the cubital and radial joints, where several long, strong spines, opposed by the terminal claw (or digital joint), form a powerful grasping or raptorial organ, but one considerably further removed than the analogous portion of structure in

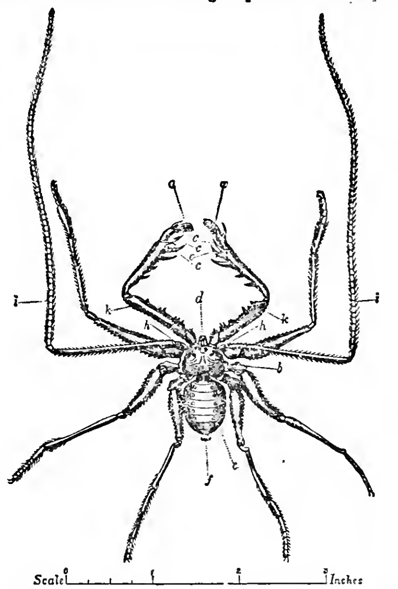

FIG. 23.—*Phrynus medius*, Koch. *a, a*, movable fangs or claws on fourth joint of palpi; *k, k*, forming, with claws, *c c*, on third joint, modified didactyle claw; *b*, cephalo-thorax; *d*, falces; *e*, abdomen; *f*, button at end of ditto; *h, h*, eyes; *i, i*, long palpiform legs.

Thelyphonus from the didactyle claw of the Scorpionidea. Between the maxillæ, and issuing from the fore margin of

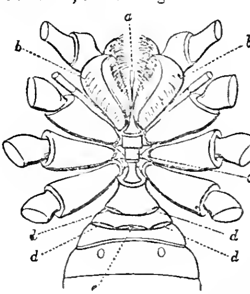

FIG. 24.—*Phrynus* —— ? portion of under side. *a*, labium *b, b*, maxillæ; *c*, sternum; *d...d*, orifices of respiratory organs; *e*, genital aperture.

the sternum, is a narrow, elongated tapering *labium*, in some species bifid at its extremity; the presence of a distinct sternal lip, or labium, is another mark of affinity to the Araneidea.

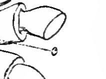

FIG. 25.—Falx and fang of *Phrynus reniformis*. Pallas.

The *legs* (seven-jointed) are long and generally slender, though the coxal joints of the three hinder pairs are long and strong, and articulated laterally to the sternum. The legs of the first pair are palpiform, and of great length and tenuity, the three terminal joints forming one long slender tapering portion, which is however subdivided into a great number of minute homogeneous articulations without any terminal claw; each tarsus of the remaining three pairs is divided into three articulations, ending with two curved claws; and in some species the tibial joint of the fourth pair is also tri-articulate. Probably the subdivision of the fourth pair of legs varies in other species also. The coxal joints of the first pair are, as it were, crushed in behind the maxillæ and above the coxæ of the second pair, as in Thelyphonus. The extreme articulation of each tarsus has a peculiarity never (it is believed) noticed before; its upper side being covered, throughout its length, with a separate integumental plate, prolonged at its fore extremity into a corneous, slightly bent, claw-like apophysis, forming a kind of third claw above and between the two ordinary ones. These latter spring from a supernumerary or heel joint, which has a short, conical, tooth-like spur beneath it, representing the usual third claw in other groups.

The *eyes*, eight in number, are placed in three groups, forming a very obtuse angled triangle on the fore margin of the caput. Two eyes, seated transversely, and near together in the medial line, constitute the apex of the triangle, which is directed forwards; the other two groups are of three eyes each, closely grouped in a triangular form, one on each side, about parallel with the second pair of legs.

The *abdomen* is oval, of a somewhat flattened form, and joined to the cephalo-thorax by a narrow pedicle, showing, in this also, a near approach to the Araneidea; it consists of ten quasi-segments, or articulations, formed, as in the other families of the order, by a series of upper and lower transverse corneous plates, having an, apparently continuous, cartilaginous integument between the two series of plates, and terminating with a button-like joint, or process, at its extremity. On the under side are two parallel rows of impressed spots, two, in a transverse line, in each of the fourth and three following sub-abdominal plates; but, apparently, like the corresponding marks in Thelyphonus, imperforate. The *organs of generation* have their external orifice beneath the posterior margin of the first sub-abdominal plate; and the external openings to the *respiratory organs*, four in number, are situated, two beneath the posterior margin of the first, and two others beneath that of the second of these plates. The *sternum* is oval, and often superficially divided into several portions by various ridges and indentations.

With regard to the INTERNAL STRUCTURE of the Phrynides, the *respiratory system* is pulmo-branchial, the orifices to these organs being four in number, and placed as above mentioned.

The *nervous system*, according to Van der Hoeven, appears to be very simple, consisting of a large thoracic bi-lobed ganglion, from which four pairs of lateral nerves issue, while a double nervous chord runs back through the connecting pedicle into the abdomen, where it divides into two divergent branches, from which the various nerves are distributed to the different parts of the abdomen.

GENERAL REMARKS.—The family Phrynides comprises but one genus, *Phrynus* (Olivier), which, according to the most recent publication upon it (A. G. Butler, *l.c. supra*), includes twenty species only, all confined to the tropical regions of the world. The individuals of most of these species appear to be of rare occurrence, or, at least but rarely observed, and the family has, comparatively speaking, received but little attention. It is, however, one of great interest and importance, and deserves more elaborate and careful treatment, especially in regard to its habits and internal anatomy, for it undoubtedly forms a plain passage from the Scorpionidea (through Thelyphonus and Nyctalops) to the true spiders (Araneidea). The main external marks of affinity with this order have been noticed in speaking of the different portions of external structure of the Phrynides.

Order VII.—ARANEIDEA.

We have come now, by an easy transition from the Phrynides, to the last order of Arachnids—*Araneidea* or True Spiders (figs. 26, 27, 28). And first, with regard to

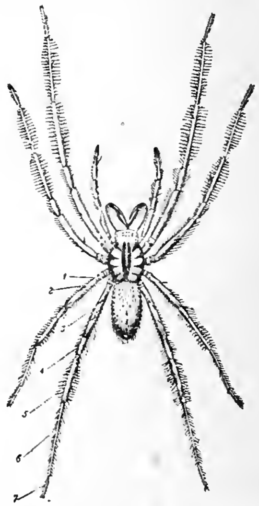

FIG. 26.—Spider (*Cambridgea fasciata*, Koch). Adult male.

their EXTERNAL STRUCTURE, they consist, like others of the sub-class Arachnida, of a body divided into two parts—cephalo-thorax and abdomen; but these are united only

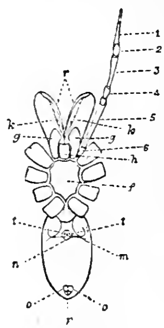

Fig. 27.

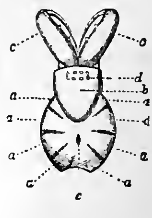

Fig. 28.

FIG. 27.—*Cambridgea fasciata*, adult male, under side, with legs and one palpus truncated. *f*, sternum; *g*, *g*, maxillæ; *h*, labium; *k*, *k*, falces, with *r* fangs of ditto; *m*, one of ordinary spiracular orifices (the corresponding one on opposite side not lettered); *n*, genital aperture, leading, in the male, only to spermatic vessels; *o*, *o* spinners; *p*, anal orifice; *t*, *t*, extra pair of spiracular openings; 1, digital joint of palpus, 2, palpal organs; 3, radial joint; 4 cubital; 5 humeral 6, axillary.

FIG. 28.—The same, upper side of cephalo-thorax. *a*...*a*, coalesced thoracic segments; *b*, caput; *c*, *c*, falces; *d*, eyes; *e*, central indentation.

by a slender pedicle, and neither is segmented, ringed, or articulated, nor (in respect to the abdomen) covered with horny plates, except in two instances—*Liphistius desultor* (Schiödte) and (but partially only) *Tetrablemma medioculatum* (Cambridge), both exceedingly rare and remarkable species. The *cephalo-thorax*, though undivided, yet shows by its various, and more or less strongly marked, converging grooves and indentations, that it is composed of the ordinary cephalic and thoracic segments soldered together; and, although these segments form but one undivided portion of structure, it is necessary to speak of it frequently by the names of its two portions—caput and thorax. The caput is almost always easily traced, forming a kind of wedge-shaped portion, jammed (as it were) into the first of the thoracic segments, and giving one the idea, in most cases, of its fore part having been to a greater or less extent truncated or lopped off (fig. 28, *b*). Similarly the last of the four thoracic segments has the appearance of having been driven in to meet the caput, all the segments thus converging, on the upper side, towards a common fovea, or more or less deep central indentation (fig. 28, *e*), and on the under side forming a sternum (or sternal plate), in which, however, no appearance of segmentation is generally visible beyond small eminences opposite to the articulation of the legs, with which the number of the thoracic segments, as seen above, agrees. The integument of the cephalo-thorax is either hard, horny, or coriaceous, generally more or less clothed with hairs and bristles, and sometimes, though more rarely, with tubercles and spines; occasionally it is perfectly smooth and glabrous. The *eyes*, when present, are two, four, six, or eight, and are very variously, but always symmetrically, disposed on the fore part of the caput (figs. 28, 29, 30). The number and general position of the eyes form valuable characters for the formation of genera; while their relative size is strongly characteristic of species. The eyes of spiders, like those of other Arachnids, are always simple.

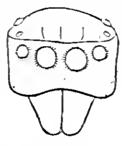

Fig. 29 —Caput of *Attus* —— ? showing position of eyes.

The *legs*, eight in number, are articulated to the sternal plate (mentioned above) which forms the under side of the cephalo-thorax; in one genus, however (*Miagrammopes*, Cambr.), found in Ceylon and Australia, no sternum properly so called exists, the legs being articulated to the continuous under side of the cephalo-thorax. Except in one or two species the legs are seven-jointed, and variously furnished with hairs, bristles, and spines. Many spiders have a kind of pad of closely set papillæ-form hairs beneath the extremity of the tarsi of some or all the legs, and often extending along the whole of the under side of the joint. This pad enables the spider to run over smooth vertical surfaces, acting as a kind of sucker, partly by atmospheric pressure, and partly (Mr Blackwall thinks wholly) by means of a viscid secretion from the papillæ-form hairs. Each tarsus ends with either two or three more or less curved or bent claws, commonly (but not always) pectinate or finely denticulated; these (with other opposed serrated claws, in some groups) are used in traversing their webs, and as hooks to give a tension to the line of their snares by alternately pressing and straining upon them; the spines and bristles are used also in many cases in the actual construction of the silken snares in which spiders entrap their prey. The spines on the legs of some spiders which excavate cylindrical holes in the earth (lined with silk and closed with a hinged lid) are very strong, and well suited for digging out the soil. The males of some species, again, have a curious row of short, closely set, curved, spiny bristles along a portion of the upper side of the metatarsi of the fourth pair of legs; the use of this row of bristles (called the *calamistrum*) is alluded to further on. The length of the legs in spiders (both actual and relative) is very various; and the differences between them, as well as their armature and terminal claws, furnish valuable characters, often generic, and always important in the determination of species.

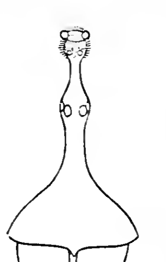

Fig. 30. — Caput of *Walckenaëra acuminata*, Blackw., showing position of eyes.

The *falces*, two in number, are articulated immediately below the fore margin of the caput; their direction is various, ranging from a line parallel to the plane of the cephalo-thorax to one perpendicular to it; they are in general opposed to each other, and in most cases are armed with teeth on their inner surface, especially towards the extremities; each also terminates with a movable curved fang, which, when not in use, is (according to its mode of articulation) folded down either across the inner side of the extremity of the falx, or (as in one extensive family, *Theraphosides*) backwards along its length; by means of these fangs, which are internally channelled and perforated at their extremities, a poison secreted within the caput is instilled into the wound made by them, proving, no doubt, fatal to the spider's prey, and often nearly so to human beings. Not to dwell upon the, probably exaggerated, accounts of the Tarantula, there are well-authenticated instances of recent date in regard to the very deadly nature of the poison of quite a small spider, *Lathrodectus Katipo* (Ll. Powell), found in New Zealand (*Trans. N. Z. Instit.* iii. p. 56; also *Id.* ii. p. 81, and iii. p. 29). A larger European species of the same genus, *L. oculatus* (Walck.), also bears the reputation of being venomous.

The *maxillæ* are a conspicuous, as well as an important, portion of structure in the Araneidea; they are two strong pieces situated immediately behind the falces, exceedingly varied in form and strength, and articulated to the fore side of the sternum between the basal joints of the first pair of legs. Their real direction is always divergent, *i.e.*, outwards from each other, but as in most cases the inner extremity is produced into an apophysis of greater or less size (sometimes following the direction of the maxilla, sometimes curved so that its extremity almost touches that of the opposite maxilla), the maxilla itself often seems lost in the part which projects from it. Owing to this, the palpus which springs from each maxilla, although really always springing *from its extremity*, appears more frequently to issue from *its outer side*; and, in fact, it can hardly in those cases be described (without leading to some confusion) as issuing in any other way. The form of the maxillæ, together with the apparent point of palpal issue, constitutes one of the most valuable characters for the establishment of genera.

The *palpi*, issuing from the maxillæ as just described, are two (in both sexes of *many*, and in the female sex of *most* species, leg-like) limbs, of five or (counting the basal joint—maxilla—to which each is articulated) six joints; in the female spider the palpi generally end with a single, and sometimes denticulate, curved claw; in some instances, however, there is no terminal palpal claw; but in the male, the third (*cubital*) and fourth (*radial*) joints of the palpi are (the former often, the latter always) characterised by prominences, spiny apophyses, or protuberances, which furnish some of the strongest, as well as most tangible, specific characters of that sex; the last (or *digital*) joint of each palpus (in the male spider) is generally more or less concave, and always includes, either within its concavity or articulated to its under side, a (frequently complex) congeries of corneous lobes, spines, and spiny processes, in some instances articulated to each other so as to be capable of being opened out as by hinges. These are not developed until the spider arrives at maturity. Up to that period the digital joint has a tumid and somewhat semi-diaphanous appearance, and, although commonly smaller, bears the same general form that it has after maturity. These processes, or, as they are called, *palpal organs*, are connected with the process of reproduction—the fecundation of the female. This subject, however, we shall have occasion to refer to again. The palpi are generally furnished more or less with hairs, bristles, and spines, like the legs; and like them, also, are reproduced after accidental loss.

The *labium* is also another important portion of structure; it is situated at the fore extremity of the sternum, between and in front of (or rather beneath) the maxillæ; it is of varied form and size, and stopping the gap between the maxillæ, it completes with them the inferior and lateral boundaries of the mouth, the falces forming its upper limits. The labium is always present, except in a new and very remarkable Brazilian spider, *Aphantochilus Rogersii* (Cambr.), in which the labium is wanting, and yet not wanted, because the maxillæ, in this instance, close up to each other, leaving no gap between them.

Between the labium and falces is another portion of structure, the *tongue*; it is, no doubt, by the aid of this that the act of swallowing the juices of insects, when expressed by the falces and maxillæ, is effected; that, in fact, the spider eats without being choked. No use hitherto has been made of the tongue in spiders for purposes of classification, but the form of the *labium* is very useful for the characterisation of genera. These parts —falces, maxillæ, labium, and tongue—thus complete the mouth-parts of a spider.

The *sternum* has already been mentioned; its form varies from oval to heart-shaped, and sometimes somewhat pentagonal; its convexity also varies considerably; its use in classification is rather limited, but with its clothing of hairs, bristles, or pubescence, or its sometimes glabrous nature, it generally has some specific importance. In one known genus only, as mentioned above, is the sternum wanting.

The *abdomen* is exceedingly varied in form in different families; it is united to the cephalo-thorax by a short narrow pedicle, and generally terminates with organs for spinning; in one species, *Liphistius desultor* (?) (Schiödte), the spinners are placed near the anterior part of the under side of the abdomen; and in another, *Mutusca mammosa* (Cambr.), one pair only are so placed, the rest occupying the ordinary position. The number of spinners varies—two, four, six, or eight; they are placed in pairs, and when a fourth pair is present it is, usually as a single one, united throughout its length (but with often a line of division visible), and occupying a transverse position in front of the rest. It is but very lately that spiders have been observed with two spinners only; see "Spiders of Palestine and Syria," O. P. Cambridge, *Proc. Zool. Soc.* 1872, p. 260; *Ann. and. Mag. N. H.* 1870, pp., 414–417, *Ibid.*

The *spinners* consist of from one to three joints, and vary greatly in size and structure, as well as in number, but their use in classification has not hitherto been as great as might have been expected; generally they are separate, but in *Tetrablemma* (Cambr.) they are enclosed in a kind of corneous sheath. Those of the fourth pair when present (which they are in both sexes) are correlated, but in general only in the female sex, with the calamistrum, or double series of curved bristles before mentioned, on the metatarsi of the fourth pair of legs. The function of the calamistrum has been proved by Mr Blackwall to be the carding, or teasing and curling, of a peculiar kind of silk, secreted and emitted from the fourth pair of spinners; when thus prepared this silk becomes adhesive, from its minutely divided and elastic fibres; and, disposed about the lines of the spiders' snares, it renders more easy the entanglement and capture of their prey. Immediately above the spinners is a small nipple-like prominence which indicates the anal orifice.

The abdomen is covered with a continuous integument neither annulate nor segmentate; in one species, however (before mentioned), *Liphistius desultor* (Schiödte), the upper side has a longitudinal series of transverse corneous plates, like those of the Phrynides; and something of a similar kind, but less marked, is observable in *Tetrablemma medioculatum* (Cambr.), a very rare and remarkable little spider found in Ceylon. The epidermis of the abdomen is of various kinds and consistency in different groups, sometimes excessively thin and tender, at other times tough and coriaceous, and sometimes hard and horny, with a varied armature and clothing of hairs, bristles, pubescence, tubercles, and spines, sometimes being, however, perfectly bare and glabrous; its colours, also, and the patterns produced by their distribution, vary exceedingly. Underneath the fore extremity of the abdomen are placed the external openings to the respiratory organs; these apertures consist of a narrow slit or orifice under the fore edge of round or oval scale-like plates, placed on each side of the median line; such plates are in some spiders four in number, but for the most part only two. Other spiracular openings also exist in many spiders, both at the anterior part of the under side (fig. 28, *t*, *t*) and near the spinners (Siebold), but these are usually far less perceptible than the others before mentioned, and often discoverable with great difficulty. The ordinary pair of spiracular plates are in general very conspicuous, commonly differing in colour from the surrounding surface, and sometimes slightly pubescent. They occupy each side of the median line at the extreme fore part of the under side of the abdomen; and between them is, in the male spider, a very minute orifice which leads to the seminal organs; while in the same situation in the female is an aperture usually rather conspicuous, always of characteristic form, and often furnished with a corneous process of greater or less development. This aperture is the vulva, and the process (when present) probably has the function of an ovipositor. The form and structure of this aperture is of great use in the determination of species, but until the female spider attains maturity no aperture at all is visible. The orifices to the breathing organs are fringed with hairs or lashes, and open and close by an internal muscular arrangement. The other pair of spiracular plates, when present, are in some cases close behind those just above mentioned, but more commonly at some distance further towards the hinder extremity of the abdomen.

On the upper side of the abdomen may be seen in many spiders several impressed spots or dots, differing in number and position in different genera and species, but always placed symmetrically. These, considered by Treviranus as stigmatic openings, are probably indicated points of fixture for muscles beneath the integument, being apparently imperforate. Smaller puncture-like marks are also often visible on the under side, and are perhaps similarly caused. The hairy clothing of the abdomen (as well as of the cephalo-thorax and other parts), variously tinted and coloured, gives the specific pattern to the spider from its diversified distribution; and when such clothing is absent, the pattern is often equally distinct and varied, arising in such cases from a pigment in the coats of the integument itself.

Internal Organisation.—The *Muscular System* of spiders is very similar to that of the rest of the Articulata. The muscles are formed of numerous parallel fibres traversed by very marked striæ; these muscles are attached to the different portions of the tegumentary system, and move the various parts of the body by the contraction of their fibres. Those which set in motion the falces, the maxillæ, and the coxæ of the legs, are attached to the thorax, and radiate to all these parts from a centre, marked externally by what has been before spoken of as the *thoracic indentation*, or *fovea*. The other joints of the legs move, one after the other, by means of small and exceedingly fine muscles, of the two kinds ordinarily known as *extensors*, to raise the joint, and *flexors*, to lower it. All these muscles act with great rapidity, and enable the legs to move in every direction according to the mode in which the various joints are articulated. The differences in the relative strength and volume of the muscles are very great; those, for instance, by which the fangs of the falces are moved are exceedingly powerful; the abdomen being generally soft, its integument does not furnish such firm points of attachment as that of the thoracic region, and yet the spider can move its abdomen with the greatest ease in every direction. Beneath the integument, at the fore part of the under side, two ligaments are attached to a membranous plate, situated under the branchial operculum, and at the hinder part, round the ring which encircles the spinners and the anus. The fore half of these ligaments is cartilaginous, while the hinder half is composed of contractile muscular fibres, and by means of those muscles the spider moves its abdomen. Two other pairs of muscles may also be particularly mentioned,—one pair inserted under the membrane in the junctional pedicle, the other leading round the respiratory organs: the office of these is to open or close the branchial opercula, and to draw the sexual organs backwards or forwards. The spinners are moved by special muscles similar to those of the legs. (Simon, *Hist. d. Araign.*)

The *Organs of Digestion* consist of a large sac, or stomach placed in the cavity of the cephalo-thorax, and fastened to its arch by a strong muscle; this muscle passes round and through the stomachal sac; *into* the stomach a tube (œsophagus) leads from the mouth, and *from* it ten lateral branches or cæca (five on either side) issue, passing down the sides to the origin of the legs, and, curving round, end in a reservoir placed below the stomach. This reservoir is connected with the stomach by the muscle mentioned above, and divided from it by a solid plate into which this muscle is inserted; it, in fact, forms a kind of second or lower stomach into which the juices forming the spider's food are forced from the upper one by muscular action.

Out of the stomach the alimentary juices go into a tube or intestine, which is much contracted in size in passing through the junctional pedicle into the abdomen, but enlarges a little within the latter; this tube curves over for some distance in a line parallel with the dorsal integument; it then drops down suddenly, forming a large loop, and so passes into a large rounded pouch (rectum), in which the undigested portions of food collect, and thence pass out through the anus, situated, as before observed, at the extremity of the abdomen just above the spinners. The abdominal intestine is imbedded in a mass of fatty globules, from which bile is secreted; the bile passing by means of biliary ducts (into which urinary organs also pour their contents) into the rectum. Digestion is effected by means of a gastric juice secreted by appropriate glands between the lateral cæca, and thence poured into the stomach (Simon, *l.c.*, after Dugès).

Walckenaer, *Ins. Apt.*, following Treviranus, gives a slightly different account of the digestive apparatus of *Tegenaria domestica* (Walck.) Probably a certain amount of variation would be found in the details of form and structure of the stomach and intestinal canal, and other organs of digestion, in different species; but the general plan of the digestive arrangement is the same. It is an undecided question whether the œsophagus of spiders can pass any substance except the juices of their prey. See O. P. Cambridge in *Entomologist*, May, 1870, pp. 65–67; and *Ann. and Mag. N. H.*, Dec. 1872; and F. Pollock, *Id.*, Oct. 1872.

Organs of Circulation.—As in some other groups of Arachnids a strong muscular tube or vessel (divided into four chambers)[1] runs along beneath the dorsal integument of the abdomen, following the integumental curve; this dorsal vessel (or heart) varies in form in different species, and is enveloped in a fine fibrous tissue, which forms a *pericardium*.[2] The several chambers of the heart communicate with the pericardium by means of small elongated orifices (auriculo-ventricles) placed at the constrictions where the chambers are separated from each other; through these orifices the vital fluid passes *into*, but cannot pass *out of*, the heart. This latter operation is effected by the contraction of the heart, which forces the fluid forwards into a tube or artery issuing from the first chamber; this tube—aorta—passes through the junctional pedicle, and entering the thorax, divides into three pairs of arteries. The upper pair follow the dorsal line and give off blood-vessels to the eyes, the falces, and other parts of the mouth; the second pair, intended to give nourishment to those parts, pass over the stomach; and the third are imbedded beneath that organ, and emit arteries to the legs, extending to the very extremity of each. These three pairs of arteries reunite forwards and form a collar round the cerebral ganglion; and from thence a tube[3]—abdominal or posterior aorta—passes backwards under the ganglia through to the abdomen, continuing quite to the spinners; this tube furnishes numerous branches to the organs which it passes in its course. From the general circulation the vital fluid is brought into two large longitudinal reservoirs within the lower face of the abdomen, by means of sinuses or canals formed by the interstices of the muscles; these anastomose and pour their contents into the reservoirs just above mentioned; from them the fluid[4] penetrates the branchial organs, and being there reoxygenated, is carried back to the pericardium by four brancho-cardiac vessels; from thence it passes into the dorsal vessel or heart through the auriculo-ventricles[5] above named. Muscular contractions and dilatations appear to be the means by which the fluid is propelled through the sinuses that bring it to the branchial organs for oxygenation (Simon, *l.c.*, after Emile Blanchard, and Dugès).

As has been already observed in several notes, there is some difference between the above account of the circulatory system and that given by Claparède; probably the organs of circulation vary, somewhat in different species. One point of difference, however, between the above and Claparède's description is of importance, that is, the difference which is mentioned in note (4) below. The idea that the blood "penetrates" the branchial organs may have been led up to by the apparently unfounded, but confidently pronounced opinion that these organs were true analogues of the lungs of the Vertebrata; whereas, if the blood does not penetrate them, but is merely oxygenated in its general passage by and round them, their real tracheary nature (as seems to be the better opinion now) is strongly confirmed; and hence the hitherto widely-received division of Arachnids into *pulmonary* and *tracheary*, based upon the idea of the distinct nature of the pulmo-branchiæ from the tracheæ, falls to the ground; the more especially since, whatever the difference may be between the ordinary tracheæ and the pulmo-branchiæ, both are found in the same individual, in the order we are now considering—Araneidea.

Organs of Respiration.—From what has just been said, it seems hardly proper to base any definition of the respiratory organs of spiders on the supposed essential distinction between the pulmo-branchiæ and tracheæ. Such difference as there is, and it is indeed an important one, seems to be this, that whereas the tracheæ are lengthened tubes, which convey the air in very small volumes to different parts of the body, and so oxygenate the vital fluid in its passage, the pulmo-branchiæ are modified tracheæ, localising, so to speak, within a peculiarly furnished sac, a considerable volume of air in the immediate course of the large sinuses, in which the used-up vital fluid is re-collected previous to its return to the dorsal vessel. This arrangement, no doubt, marks a higher state of organisation than is possessed by those Articulata furnished with merely simple tracheæ; it is a progress from a diffused to a localised system, but still it seems essentially distinct from the lungs of vertebrates, in which the *blood is carried to the air and permeates every portion of the air-vessels*, and not the air to the blood, as is really the case in regard to both the pulmo-branchiæ and tracheæ of spiders. It is not a matter, perhaps, of prime importance, but if the above views be correct, it would seem better to relinquish the name of pulmo-branchiæ, since there is not only no real analogy to the lungs of

[1] Claparède (*Etudes sur la circulation du sang chez les Aranées du genre Lycosa*), in describing the dorsal vessel of a young Lycosa, says that at that age no such chambers exist, and questions whether or not the chambered form such as Newport and Blanchard have described in the scorpion, does or does not exist in the adult Lycosa. *Vide supra*, p. 285, on the heart of the scorpion.

[2] The existence of this is also questioned by Claparède, who speaks of the heart as placed "not in a distinct organ—pericardium—but in a certain indefinite space—lacune péricardique," (*l.c.*)

[3] Claparède could not find this in Lycosa, (*l. c.*)

[4] Claparède (*l. c.*) says, on the contrary, that the blood "never penetrates between the leaves (*feuillets*) of the respiratory organs," but is reoxygenated in its close passage by them.

[5] Claparède says that *all* the fluid which comes from the respiratory organs passes into the heart through the *foremost pair* of these openings.

mammal, but just as little to the gills of a fish. We would propose, therefore, to distinguish these modified and localised tracheal sacs by the name of *sac-tracheæ*, the ordinary ones being designated *tube-tracheæ*.

In some spiders, Theraphosides (including the giant spiders of the family better known as Mygalides), the respiratory organs are solely sac-tracheæ; these are in this case four in number, and placed in two pairs on the lower side of the abdomen. Their external orifices are protected by spiracular plates (as before noticed); in other spiders there is, close in front of each of the fore-pair of sac-tracheæ, an orifice leading to tube-tracheæ. In some few spiders a kind of supernumerary spiracular slit or opening is visible near to the ordinary one, but not always similarly placed. A pair of others are also visible close behind the sexual aperture in *Cambridgea fasciata* (L. Koch) (fig. 27, *t*, *t*). These openings probably lead to other tube tracheæ. We have also noticed slit-like openings similar to those above mentioned in some undescribed species of Drassides, and some also exist in the well-known European spider, *Argyroneda aquatica.*[1] Tracheal openings also exist, according to Siebold, near the spinners. The sac-tracheæ of spiders are of the same construction as the organs described as pulmo-branchiæ in the family Scorpionides. The following short description is abstracted from E. Simon, *l.c.*, following Emile Blanchard :—"The respiratory apparatus is contained in sacs beneath the stigmata; these sacs are globular and flattened, formed by a silvery white membrane. Each of them contains a body not fastened to the walls of the sac, but lodged as in a chamber; this body is composed of sixty or seventy plates (lamellæ) lying one upon another like the leaves of a book. Each one of these apparent *plates* is in fact itself a flattened sac, with an opening on its lower side communicating with the outer air admitted through the spiracular orifices. The walls of these numerous sacciform lamellæ consist of two membranes of different composition, the inner one hard, the other soft, and between them is a very fine strong network analogous to the spiral thread of the tracheæ of insects."

The inspiration and expiration of air in these sac-tracheæ are effected in a very simple manner. To the outer wall of the sac a broad and strong ligament is attached; this ligament ascends across the abdomen, and is fixed to the walls of the heart. 'Each movement of this organ, diastole or systole, strains or slackens the ligament, which in its turn raises or lowers the tracheal sac, and by these means the air is either drawn into or expressed from it (E. Simon, *l.c.*, after E. Blanchard).

According to Treviranus, *l.c.* (*vide* Jones, *Anim. Kingdom*, p. 416), who, however, makes them four pairs on each side, there are, in the Araneidea, four pairs of spiracles (four on each side of the cephalo-thorax) situated immediately above the insertions of the legs. He also notes four stigmata (in two pairs) on the upper side of the abdomen, and a pair on the under side; the former undoubtedly exist, in some species at least, but the latter appear to be imperforate, and are probably only points of muscular attachment. It does not appear that the tracheæ leading from the thoracic spiracles have ever been traced; they are, perhaps, exceedingly delicate in their walls, and probably of no great length, and hence after death, when the air has left them, they would be exceedingly difficult to detect. There remains much, doubtless, to be yet discovered in regard to these and other minute details of the internal organisation of spiders.

The Nervous System.—In the order *Acaridea*, as it has been above observed, the nervous matter is concentrated into one large mass or ganglion, whence it branches out to the rest of the body. In the *Pycnogonidea* the nervous system consists of a longitudinal series of large ganglia, of which the four abdominal ones are sessile. In the *Scorpionides*, also, it consists of a longitudinal series of eight ganglia distributed throughout the whole body, and united by a triple nervous chord; and now in the *Araneidea* (as in the *Solpugidea*, *Thelyphonidea* (*Phrynides*), and indeed in the *Phalangidea* also), we seem to have a compound of these two modifications. Thus, in the *Araneidea* the nervous matter is, in general, concentrated into two masses, one placed within the fore part of the cephalo-thorax, just above the œsophagus; this (the cephalic or so-called cerebral) ganglion sends out fine nervous threads to the eyes, falces, and labium; the other mass (thoracic ganglion) is situated just behind the former, and occupies a large portion of the thoracic cavity; it is of a flattened disc shape, and is united to the cephalic ganglion by short but broad connectors, forming a narrow collar round the œsophagus. This thoracic ganglion is formed by an approximation and soldering together of the different ganglia which exist separately in the scorpions. A proof of this is furnished by the fact, that in the young of some of the Araneidea, furrows of greater or less depth show the junctional points of the different ganglia.

From the thoracic ganglion lateral nerves issue to the legs and palpi; besides which a fascia of nerves runs backwards through the pedicle into the abdomen, and these subdividing, branch out to all its different organs (Simon, *l.c.*) A modification of the above exists in the Theraphosides, where there is a special enlargement, or ganglion, just within the fore part of the abdomen, before the nervous fascia subdivides and branches out into that part of the body; probably this modification would be met with also in many other spiders (Cuvier's *An. Kingdom*, pl. 2, Arachnides; and Treviranus, *l.c.*, pl. 5, fig. 45).

The *Organs of Reproduction* in the *female* consist of two long ovaria placed longitudinally within the ventral surface of the abdomen; these unite and form a short broad oviduct, having an external opening of various form beneath the upper end of the abdomen between the spiracular orifices, as before noted under the head of external structure.

In the *male* the organs for the secretion of the seminal fluid consist of two long narrow convoluted tubes, occupying the same relative situation as the ovaria in the female, and also opening outwardly through a common but exceedingly minute orifice in a similar position. No intromittent organ has been discovered in any instance; and it is not long since that the probable way in which the impregnation of the female takes place (at least in some cases) has been at all certainly noted. It has been before remarked that the peculiar corneous lobes and spiny processes connected with the digital joint of the palpi—palpal organs[2]—in the male, are used in the course of copulation; but araneologists were not (and probably are not now) agreed as to their real office in generation. A distinguished author, Mr John Blackwall, went so far as to prove, as he believed, by a series of carefully conducted experiments, that the seminal organs of the male spider, above described, are in some cases wholly unnecessary for the impregnation of the female—at least so far as any external use or application is concerned—and that the palpal organs are the efficient agents in the impregnation of the female spider (*Report of Brit. Assoc.* 1844, pp. 68, 69). This, however, seemed to be contrary to all reason and analogy, and led to the hypothesis that there was some communication by a duct or ducts between the spermatic vessels in the abdomen and the palpal organs (Hermann, 1868; *Verhandlung d. Zool. Bot. Gesellsch. in Wien*, xviii. pp. 923, *et seq.*) This idea, however, appeared to be negatived by the failure of Dugès and other eminent anatomists to discover any duct in the palpus, where, if present, it would be comparatively easy to find. Another hypothesis—grounded on the fact that the palpal organs have in some cases been observed to be applied repeatedly to the mouth between their numerous applications to the vulva—was, that there might be some duct through which the spermatic fluid could pass into the alimentary canal, and so be conveyed to the œsophagus, and thus be taken from the mouth by means of the above-mentioned application to it of the palpi. The discharge of the spermatic fluid in birds into the lower intestine appeared to support the possibility of this hypothesis being true (O. P. Cambridge, *Trans. N. Z. Instit.*, vol. vi. 1873, p. 190). Another opinion, long since, and even now, held by some arachnologists, is that the male spider collects the seminal fluid with its palpal organs into the concavity of the digital joint from the minute orifice above noted; but no instance has ever been noticed in which a spider has been detected in such an employment of its palpi. An instance has been recorded in which there were *during copulation* (?) repeated embraces, and at each embrace a perfect apparent coition was effected between the sexual apertures of the male and female spider, the palpi not being used at all (O. P. Cambridge, *l.c.*, p. 191). Other arachnologists, again, have recently observed that the male spider before the act of copulation "emits from the sexual aperture a drop of sperma on a kind of small web made for the purpose, which drop he then takes up in the genital bulb of the palpi" (A. Menge, *Ueber die Lebensw. d. Arachn.* p. 36; and A. Ausserer, *Beob. ueber die Lebensw. der Spinnen*, p. 194). This would appear to settle the question; but while, at the same time, it is remarkable that an observer so accurate in observation and so painstaking as Mr Blackwall should never have observed male spiders taking the spermatic fluid from the abdominal aperture, as stated by Menge some thirty years ago, it is also remarkable that Mr Blackwall should unconsciously afford the strongest evidence in favour of the facts mentioned by Menge and Ausserer.

Dugès, in suggesting, long since, that the male spider took the seminal fluid from the aperture in the abdomen with its palpi, asked whether the palpal organs may not alternately act as an absorbing siphon and an ejaculatory organ. Mr Blackwall (*Jour. Linn. Soc.*, vii.) mentions this question of Dugès, and then states a fact which at once answers the first part of it in the affirmative, and tends to confirm

[1] In a recent paper, "Ueber die Respirationsorgane der Araneen," by Philipp Bertkau," *Arch. f. Nat.*, xxxviii, pp. 208-233, pl. 7, recorded, *Zool. Record.*, ix. p. 206, which the present writer has not had an opportunity of studying, the author appears to have come to the same general conclusions on the respiratory system of spiders as those above mentioned, and also to have discovered, in some spiders, other orifices leading to tube-tracheæ in front of the spinners.

[2] These organs are not developed until the last moulting of the spider's skin, and their development (unmistakable when complete), is an unerring sign of the spider's sex and maturity. Until this period the digital joint is more or less rounded and tumid, but it can even then seldom be mistaken for that of a female spider.

Menge's and Ausserer's statement: "A male *Agelena labyrinthica* confined in a phial, spun a small web, and among the lines of which it was composed I perceived that a drop of white milk-like fluid was suspended; how it had been deposited there I cannot explain, but I observed that the spider, by the alternate application of its palpal organs, speedily imbibed the whole of it."

That the spermatic fluid is conveyed to the female parts of generation by the male palpi is thus pretty certain; and it seems not improbable that there are more modes than one by which the palpi are supplied with the fluid. See also critical observations on this subject by Dr. T. Thorell, 1873, *Synonyms of Europ. Spid.* pp. 591–595.

Before concluding our remarks on the internal structure of the Araneidea, two of their special properties must be shortly noticed—the secretion of the poison injected into the wounds made by the fangs of the falces, and the secretion of the matter emitted as silken threads through the spinning organs.

The *poison* is secreted in two small elongated sacs (one for each of the falces), situated within the cephalothorax on either side of the alimentary canal; the sacs are connected with a membranous channel in each of the falces, the channel running completely through the fang, from an orifice near the end of which the poison is pressed out by the spider in the act of wounding its prey On the venomous nature of the poison some remarks have already been made. As to its venom in British spiders, see "Blackwall's Experiments," *Trans. Linn. Soc.*, xxi. pp. 31–37. The result of these interesting experiments is contrary to the generally received idea as to the great virulence of spider poison.

The *external spinning organs* have been mentioned above; they are usually called *spinners*, and are various in size, both actual and relative, in form and in structure, as well as in number. From the extremity of each of these organs the silk matter issues through numerous movable papilla, or *spinnerets*, which are similar to hollow bristles with enlarged bases; the papillæ vary both in form and number in different species, and from each spinneret or papilla issues an exceedingly fine thread; this, uniting with threads from all the other papillæ, forms the ordinary silk line, which though to ordinary observation simple, is composed of numberless threads from some one, or all, of the spinners. The matter from which the silk is formed is secreted in organs (silk-glands) situated within the ventral surface of the hinder part of the abdomen. These glands vary in number, size, and form in different species; they differ also in size and shape in the same species, for the secretion of different qualities of silk-matter; and each gland has a distinct duct terminating at the extremity of the spinners. The emission of silk matter appears certainly to be a voluntary act on the part of the spider; but it is a disputed question among arachnologists, whether spiders have the power forcibly to expel it, or whether it is merely drawn from the spinnerets by some external force or other. Mr Blackwall (*Trans. Linn. Soc.*, xv. p. 455; *Researches in Zoology*, pp. 242–248, and *History of Spiders of Great Britain and Ireland*, p. 12) is of the latter opinion; while Mr R. H. Meade (of Bradford, Yorkshire), in *Report of British Assoc.*, 1858, pp. 157–164, pl. 16, thinks that (from microscopic anatomical investigations which he has himself made) there is good evidence of spiders having the power to expel it, for he finds a certain muscular arrangement which would apparently suffice to give this power, and observers have actually seen the lines propelled. Mr Meade, however, need not be assumed to assert an indefinite power to expel threads of silk to any indefinite distance. The truth probably is, that spiders have, and do exercise, a general power not only of *emitting* silk matter from the secreting glands merely to and from the external orifices of the silk-tubes, but also of *propelling* it when necessary to some short distances; and that external causes (such as the movement of the spider while the end of its line is fixed, or when a current of air takes an emitted line and carries it in a direction contrary to that of the spider) also serve to draw the threads out. In all these ways, no doubt, are produced the gossamer lines which often cover the surface of the ground and herbage in autumn. In the formation of their snares spiders use the hinder or fourth pair of legs for drawing the threads tight, and apparently for ascertaining their power of tension. The third, or inferior tarsal claw, being usually strongly bent, no doubt enables spiders to perform these operations very readily. Some large groups of spiders do not spin any snares, and in them we usually find this third claw absent; while in one group, Epeïrides, whose snares are marvels of beauty and ingenuity, the third claw is very highly developed.

The snares of spiders have been made the basis of some of the primary divisions of the order. Characters, however, taken merely from habits and modes of life, can hardly be considered those on which systematic classification should be based, not to mention that those characters fail when we come to extensive groups spinning no snares at all. Short of such a use of the snares of spiders, this part of the subject is of extreme interest and importance. The Latreillian divisions of snares is fairly and generally accurate; by this method they are divided into—*Orbitelariæ*, where the plan is that of a circle or a portion of one, with lines radiating from a centre; *Retitelariæ*, where a thin sheet of web is suspended among the branches of shrubs or in angles of buildings, and held up and down by lines in all directions above and below; *Tubitelariæ*, where the snare is a silken tube, inserted in crevices, and fissures, and casual holes, and with an open mouth more or less guarded or armed with insidious lines; and *Territelariæ*, in which a tube is spun in a hole formed by the spider itself, and closed sometimes by a close fitting cork-like, or sometimes by a scale-like or wafer lid, sometimes left open, and at other times closed by the falling over of a portion of the tube which protrudes from the surface of the ground (see *Trapdoor Spiders*, by J. T. Moggridge, Lovell Reeve, London, 1873–4). With respect to the economic or mercantile value of spider silk, the idea seems to have been entertained, from a remote period, that it might not only be turned to practical use in the manufacture of silk fabrics, but also be made to pay as a mercantile speculation. The possibility of making it into articles of wear is undoubted, as instances of it are on record. Upwards of 150 years ago Le Bon of France (Languedoc) obtained, from spiders, silk which was afterwards woven into gloves and stockings; but Réaumur, appointed by the French Academy to investigate the matter, reported unfavourably, doubting the possibility of rearing the spiders together owing to their voracious and cannibal propensities. In 1777 and 1778 a Spaniard, Raimondo Maria de Termeyer, published, in Italian periodicals, two memoirs on the subject; and afterwards, 1810, at Milan, another called *Ricerche e Sperimenti sulla Seta de Ragne*, in which he takes an opposite view to that of Réaumur. The latter work is of great rarity (*vide* B. G. Wilder in Harper's *New Monthly Mag.*, xxxiv. p. 455). Termeyer constructed a small kind of stocks, in which the spider was fixed by the body, while with a little winding-machine he drew out and wound up the silk threads from the spider's spinnerets; but evidently nothing came of this further than an additional proof of the possibility of procuring and making use of spider silk, as well as of its strength and lustre; this last, however, as well as other qualities of the silk, would probably be found, as with that of various silk worms, to vary according to the species. Other experiments, with a similar general result, have been made since (*Zoologist*, 1857, p. 5835), the latest being those made by Dr B. G. Wilder, professor of anatomy in the

Cornell University at Ithaca, United States (*l.c., supra*), with *Nephila plumipes* (Koch), a large epeïrid abundant in South Carolina. His experiments appear to have been unconsciously, though surprisingly, similar, and with a similar result, to those of Termeyer; but the question as to the mercantile importance of spiders' silk appears to have hitherto elicited only an unfavourable answer. Dr Wilder, however, is still sanguine upon the point (*vide* B. G. Wilder, *l.c.*, and also in *Proc. Boston. N. H. Soc.*, October 1865, with other references there noted, as well as in *The Galaxy*, July 1869, pp. 101, 112). In *Zoologist*, 1858, p. 5922, a correspondent, speaking of the strength of the silk threads of *Nephila clavipes*, says that small birds are sometimes entangled in its webs, and that the ladies of Bermuda use the threads for sewing purposes. See also *Phil. Trans.* 1668.

Before leaving this part of the subject we must notice the office of the *calamistrum*, mentioned before in speaking of the armature of the legs of spiders. This instrument is found in the females of various genera and families; it consists usually of a closely set double row of curved spine-like bristles on the upper sides of the metatarsi of the fourth pair of legs, forming a kind of comb, whence Mr Blackwall, by whom it was first discovered and its use perceived, gave it the name it bears. Its office is to card, or curl, or tease a particular kind of silk emitted from the supernumerary spinners, mentioned above as always, in the female, correlated with this instrument; the silk so curled and carded is, owing to the fineness of its fibres, exceedingly prehensile, and being disposed about the lines of the spider's snare, serves to entangle the insects which come in contact with it (*vide* Blackwall, *Linn. Trans.*, vol. xvi. p. 471, pl. 31, 1831). *Amaurobius similis* (Bl.) and *A. ferox* (Koch) are common house spiders whose webs are thus furnished with carded silk from the supernumerary spinners. Doubts have been entertained quite lately by an eminent araneologist as to whether the supernumerary spinners are indeed true spinning organs (T. Thorell, *Synonyms of European Spiders*, p. 595, 1873). It is therefore interesting to find in *Science Gossip* (Hardwicke, London, Sept. 1874), a short article by H. J. Underhill, in which the anatomy of these spinners is described and figured from original microscopic investigations, proving the recorded observations of Mr Blackwall, and others also, as to their being true spinners, to be correct.

The white flake-like flocculi often seen floating in the air on a calm autumnal afternoon are composed of spider silk emitted by numerous immature spiders, of many species and genera, passing through the air on their lines, which being so much lighter than the atmosphere, serve to bear them away with every breath of wind. The flocculi appear to be agglomerations of fine lines, adhesive from their fineness and fibrous nature. In this respect they differ from the ordinary gossamer lines, which are merely the threads left by small and immature spiders (chiefly of one or two families) as they pass from blade to blade and plant to plant. It seems probable that nearly all spiders leave a line or lines, which proceed from one or more of their spinners, whenever and wherever they move about; and the setting in of fine weather being the signal for a spontaneous restlessness, we can hence better understand the almost sudden appearance of myriads of lines stretching over the surface of the earth, and often extending high up into the air. Numerous papers have been written on gossamer, chiefly by German and French writers, with the latter of whom the subject has been sometimes treated on the basis of the marvellous and superstitious. These lines are called by them *fils de la Vierge*.

Our space does not permit of any great detail respecting the various kinds of snares, nor regarding the way in which different spiders construct them. Accounts may be found, by Mr Blackwall, in *Zool. Journ.* 1830, pp. 181–189; as well as in the *Report of the British Association for the Advancement of Science for* 1844, pp. 77–79; *Researches in Zoology*, 1st ed. 1834, pp. 253–284; *Linn. Trans.* 1831, pp. 471–479; and *A History of the Spiders of Great Britain and Ireland*, 1861–64, all by the same author; and the exceedingly interesting details on this subject in Kirby and Spence's *Entomology*, pp. 227–267 (7th ed.), are within every one's reach. The following notes, however, gathered from the works of Mr Blackwall and others, as well as from the writer's own observations, may be of interest:—

The geometric spiders (*Orbitelariæ*) are almost the only ones whose method of forming a snare have been at all minutely recorded. When the situation for the snare has been chosen, the area intended to be filled up by it is enclosed by various circumferential boundary lines, fixed to adjacent objects, the exact shape of the area being influenced by the situation and surrounding circumstances. A diagonal thread is then spun across it, and from about the central point of this thread another is carried to the marginal line; returning to the central point along the line just spun from it, the spider carries another line to the margin, and fixes it at a short distance from the first. In this way the whole area is gradually filled up, the spider always returning to the centre along the last line spun, and starting again thence fixes a fresh one to the boundary line of the snare. The form of the snare is now that of a wheel; the next operation is to cross the radii of the wheel with ladder-like lines; this the spider does, beginning from the centre and working towards the circumference, with a single spiral line, which is fixed, or glued, with a minute portion of viscid matter, to each of the radii as it crosses by an application of the spinners; at some distance from the centre this spiral line is discontinued and another is begun; this is formed of quite a different kind of silk matter, being viscid, and retaining its viscidity in the form of "minute dew-like globules closely studding the line." It appears that when the viscid lines, intended for the capture of its prey, are completed, the spider cuts away the first, or unadhesive line, which is of no service in the entanglement of insects, its office appearing to be chiefly to strengthen the snare while the viscid line is being spun, and to enable the spider to traverse the parts with greater ease. Modifications of the above method are, no doubt, adopted by some species, but, substantially, it is believed that most orbicular snares are thus constructed.

The mode of formation of the snares of the *Retitelariæ* does not appear to have been observed, probably owing to their being made almost wholly during the night. The snare of one of these spiders, *Linyphia marginata* (Bl.), is an exceedingly perfect one of its kind, and abundant in most localities; it consists of a thin horizontal sheet of web, suspended among the branches of low evergreen trees and shrubs, by a maze of intersecting lines above, and held down firmly, on the under side, by some short, tightly-strained perpendicular lines, fixed below to others, which traverse each other in all directions; beneath the horizontal sheet of web, head downwards, the spider remains patiently watching for such insects as may become entangled in the upper maze of lines. The mode in which the horizontal web is suspended and braced down, would, without doubt, if it could be observed, prove to be a point of great interest.

Among the *Tubitelariæ* we have the observations of Mr Blackwall, directed chiefly to the formation by *Amaurobius atrox* of the peculiar fibrous and adhesive flocculus, drawn from the fourth pair of spinners by the "calamistrum," and disposed about the irregularly intersecting lines of the snare which is spun in the angles of walls, in crevices, between portions of detached rock, and other similar situations. The adhesive flocculus serves to entangle insects, and makes them an easy prey to the spider who lies in wait not far off, having formed a funnel-shaped tube of slight texture from its place of concealment to its snare.

With regard to the formation of the snares of the *Territelariæ*, Mr Gosse has an interesting passage in *A Naturalist's Sojourn in Jamaica;* it is, however, too long for quotation here. Mr Moggridge also (*l.c. infra*) has some details respecting the formation and repair of their nests by trapdoor spiders in confinement. The chief point of interest, however, in regard to trapdoor snares, is whether the hinged lid is formed in one continuous piece with the tube, and then cut out, leaving a portion unsevered to form the hinge, or whether the lid is made separately, except in that part intended for the hinge. Neither Mr Gosse nor Mr Moggridge enter into this question, though Mr Moggridge indeed speaks (*l.c*, p. 118) of his belief that, when all is completed, the spider cuts away certain threads by which the door is supported on either side of the hinge. The present writer was once told by a gentleman who had formerly resided in the West Indies, that trapdoor spiders there invariably make the tube and lid of one continuous, solid, homogeneous piece, and then cut out the lid with the falces. This account, especially as coming from a non-naturalist, seemed improbable—a spider's falces being in no way, apparently, fitted for such an operation; if, however, the fact be that the lid, instead of being of one solid piece with the tube, is merely connected with it by a few supporting threads (in accordance with Mr Moggridge's belief), these could easily be torn away by the spider's falces, and the lid would be left free, except at the point where the hinge is formed.

CLASSIFICATION.—It is impossible within our remaining space to go into detail upon this wide portion of the subject; it must suffice to say that the order Araneidea may at present be divided into about thirty-two families. These are—Theraphosides, Colophonides, Filistatides, Œcobiïdes, Tetrablemmides, Dysderides, Drassides, Palpimanides, Dictynides, Agelenides, Hersilides, Scytodides, Pholcides, Theridiides, Phoroncidides, Epeïrides, Gasteracanthides, Uloborides, Miagrammopides, Pultides, Thlaosomides, Arcydes, Stephanopides, Eripides, Thomisides, Podophthalmides, Lycosides, Sphasides, Dinopides, Salticides, Myrmecides, Aphantochilides. In these families are comprised about two hundred and sixty[1] genera based upon special details of structure; principally the position of the eyes, the form of the maxillæ and labium, the number and structure of the spinners, and some other details. The species are very numerous; probably not a tithe of the existing ones are yet described. In one family alone, *Salticides*, nearly a thousand are known.

As in all other creatures, differences of colour and markings, as well as integumental clothing and armature, serve to distinguish the species—the latter, too, are at times of generic value; but with regard to spiders particularly, in order to determine their species, it is very essential to obtain comparative dimensions from different portions of structure; thus the position of the eyes on the fore part of the caput furnishes us with the *facial space* (or the space between the margin of the caput just above the falces and the posterior eyes nearest to the medial line), and the *clypeus*, or the space between the same (fore) margin of the caput and the anterior eyes nearest to the medial line. The comparative extent of these parts is of great importance as specific characters, and they are easily observed; that part of the facial space occupied by the eyes is concisely described as "*the ocular area.*" The relative and comparative lengths, again, of the legs, and of their different joints, are strong specific characters, the first also generic. *Male* spiders when adult may, with few exceptions, be certainly distinguished in regard to their species, by the form and structure of the palpi and palpal organs, the development of the latter being an infallible criterion of maturity. *Female* spiders, again, may, in numerous cases, be as certainly distinguished by the form and structure of the genital aperture, situated in the medial line beneath the fore extremity of the abdomen; this aperture is never externally "perforate" until the last moult of the spider, and its full development is therefore an unerring criterion of the maturity of the female sex. With respect to the senses of spiders—smell and hearing—nothing appears to have been certainly ascertained; but the late Mr Richard Beck has an interesting paper upon the subject in *Entomologist*, Lond. 1866, vol. iii. p. 246. He suggests that the fine and delicate hairs of some spiders' legs may convey sounds to them. With regard to the sense of *taste* we may well conclude that spiders have this sense in considerable perfection, in the possession of a well-developed membranous tongue.

GENERAL REMARKS.—Spiders are to be found more or less abundantly in every part of the world and in almost every conceivable position; even subterranean caves, such as those of Adelsberg and the Island of Lesina, are tenanted by species peculiarly adapted by the absence of eyes to their dark and gloomy abodes. Less repulsive and forbidding in appearance than most others of the Arachnida, the Araneidea are often extremely interesting in their habits. Being almost exclusively feeders on the insect tribes, they are consequently endowed with proportionate craftiness and skill; this is shown remarkably in the construction of their snares and dwellings. The "trapdoor spider" has always been one of note in popular works on spiders' habits, and certainly the details of several different types of the trapdoor tubular nest, with the habits of the several species to which they belong, lately published by Mr Traherne Moggridge,[2] are of the greatest interest and importance. The typical trapdoor nest is a cylindrical hole in the earth excavated by the spider itself, lined with silk and closed by a lid, which fits like a valve or cork into the opening at the surface and opening by a strong elastic silken hinge, the spring of which closes it again with some slight force. Many spiders, however, live a vagabond life, and capture their prey without the aid of a snare, by springing on it unawares, or, in some cases, running it fairly down in open view; yet craft and skill are equally apparent, whatever be their mode of life and subsistence.

To say that spiders are less repulsive and forbidding in appearance than other Arachnids, is to do them but scanty justice, for numbers of species of various genera—notably among the Salticides, or jumping spiders—are unsurpassed by insects of any order, in respect both to brilliancy of colouring and the designs formed by its distribution. Some of the curious and delicate little species of the genera *Argyrodes* and *Ariamnes* are perfect marvels of metallic brilliancy and beauty. These little spiders are found living as quasi parasites, in the outskirts of the webs of the larger exotic epeïrids, and appear to live on the smaller insects caught in them; probably also spinning irregular snares of their own among the lines of the larger snare. In external appearance the young of spiders do not differ greatly from the adults, except in being generally more distinct in colour and markings; in some species the characteristic markings can seldom be well traced except in immature examples. The cocoons or nests in which some spiders deposit their eggs are very beautiful, as well as varied and characteristic in form; that of *Ero variegata* (Bl.), a little spider not uncommon in England, would arrest the attention of even an indifferent person; it is of an elegant pear shape, formed of a strong yellow-brown silk network, and attached by a long elastic stem, of the same material, to stalks of dead grass, sticks, or other substances, in shady places. Another, made by a larger spider, *Agroëca brunnea* (Bl.), is of a truncated pear shape, formed of a continuous white silk fabric, and attached to blades and stalks of living grass and rushes, by a short pedicle; it must, however, be seen

[1] No general work exists in which the families and genera of spiders are brought down to the present time, or in any degree near to it. The works of Walckenaer, *Ins. Apt.*, and Koch, *Die Arachniden*, are out of date altogether in this respect, though still of great value and importance in themselves. The work of Dr Thorell, *On the Genera of European Spiders*, Upsala, 1870, is exceedingly valuable, but it only touches incidentally upon the exotic groups.

[2] *Harvesting Ants and Trapdoor Spiders*, Lovell Reeve, 1872, with supplementary vol. 1874, illustrated with numerous plates.

soon after it is made, for the maker, as if prescient of the attraction of such a beautiful little object, hastens to daub it over thickly with a coat of mud or clay, which completely conceals its structure and beauty.

Spiders vary greatly in their relative fertility; probably many species are rare owing to a limited fecundity. The egg sac of *Agroëca brunnea* (Bl.) contains about forty or fifty eggs, that of *Xysticus claveatus* (Walck.) about twenty, that of *Ero variegata* (Bl.) not so many, while that of *Oonops pulcher* (Templ.) contains usually no more than two. Some spiders, however, perhaps most, construct more than one cocoon.

From their mode of life spiders attain (as we should naturally suppose) their largest size, and are found in their greatest profusion, in the tropical regions; while in more temperate climates, where the members of the insect tribes are smaller and their species fewer, we find spiders in general of comparatively smaller dimensions and less numerous in species. One of the largest known spiders, *Eurypelma Klugii* (Koch),—Fam. Theraphosides—found in Brazil, measures upwards of two and a half inches in length, with legs nine inches and upwards in span; while the smallest known spider, *Walckenaëra diceros* (Cambr.), found in England, is but $\frac{1}{28}$th of an inch in length. Tropical countries, however, although some of their spiders are giants, have numbers of small size. Numerous species have been procured from Ceylon measuring no more than from $\frac{1}{12}$th to $\frac{1}{20}$th of an inch in length.

Spiders, besides being skilful and crafty, are very cleanly; one of our common Saltici, *Epiblema histrionica* (Koch), may often be seen brushing and cleaning its forehead and eyes with its hairy palpi, as a cat uses its paws for a similar purpose. Probably most spiders, like the Crustacea, have the faculty of reproducing a lost limb. Instances of this are numerous (see Mr Blackwall's experiments, *Report of British Association* before cited), but a reproduced limb is seldom or never equal to the original one in size; this accounts for the frequency of examples captured with one or more legs, or a palpus, of dwarfed and stunted dimensions. Many spiders show great attachment to their eggs and young. The female Lycosa will seize her egg sac again and again if it be taken from her, only relinquishing it at last when apparently convinced of the hopelessness of retaining it. A pretty little spider, not rare among weeds and garden plants, *Theridion carolinum* (Walck.), carries its egg cocoon within its legs, and searches for it anxiously if compelled to drop it. Many also of the genus *Clubiona*, as well as others, brood over their eggs and tend upon their young until they disperse to find their own means of subsistence. The food of very young spiders is probably wholly derived from the moisture of the atmosphere. Spiders are great drinkers, and suffer severely from drought. Mr Blackwall relates that an emaciated, half-dead example of *Micaria nitens* (Bl.) grew immediately plump and strong after a draught of water.

In speaking of the better qualities of spiders, their attachment to their young, and the frequent fondness for each other evidenced by the apparently happy life of the male and female of some species in the same web, we must not overlook the other side of the picture. It has been well authenticated that in some species of Epeïrides the female will seize and devour the male even immediately after the exercise of his natural office, which indeed he has to undertake with great circumspection and care to be able to accomplish at all. From this propensity of the female, we may account for the gradual lessening in size of some male spiders in comparison with that of the females, by a kind of sexual selection, since it is obvious that the smaller the male the better his chance of escape (see O. P. Cambridge in *Zoologist*, 1868, p. 216, and in *Proceedings Zool. Soc. Lond.*, 1871, p. 621, and also Vinson's *Spiders of Bourbon and Mauritius*), and thus selection would operate until the males became so small as only just to be able to fulfil the office of impregnating the female. The male, nearly always the smallest, is in the case of some epeïrids and Thomisids not $\frac{1}{10}$th or even $\frac{1}{15}$th of the length of the female, and sometimes not more than $\frac{1}{1300}$th part of her weight, and less then $\frac{1}{1800}$th part of her volume (A. W. M. Van Hasselt, *Arch. Neerland*, tom. viii.) As a rule, however, the difference in size between the male and female spider is not nearly so great. Spiders are unable to fly, and the mode adopted by many species, and myriads of individuals, to make up for this by sailing away on their silken lines, has been mentioned; but lately a beautiful species of Salticides, *Attus volans* (Cambr.), *Ann. and Mag. N. H.*, September 1874, found at Sydney, N.S.W., has been described and figured, with large flaps or lateral extensions of the abdominal integument, by means of which the spider can sustain itself in leaping from plant to plant; it has power to elevate and depress these flaps at will.

The voracity of spiders is well known, and the propensity above noticed of the female to devour the male is but one instance of general voracity; but though thus voracious, spiders can endure extreme fasting with impunity. A small spider enclosed in a glazed case, lived and appeared healthy for eighteen months without food; if it had any nourishment at all during this time, it could only have been the very slight moisture that might exude from the skin of a lately stuffed bird in the case, *Zoologist*, 1853, p. 3766. Other instances are also on record of fasts, almost or quite as long, and borne equally well.

ENEMIES OF SPIDERS.—Preying upon all the insect tribes, and occasionally upon lizards (F. Pollock, *Ann. N. H.*, October 1872) and earth-worms (E. Simon in *Ann. Soc. Ent. France*, 1873, 5 sér. tom. iii. p. 114—and *Zoologist*, 1856, p. 5021), spiders are also themselves preyed upon by both lizards and insects. More than one species of parasitic hymenoptera tend to keep spiders within due bounds; but little has yet been done towards working out these parasites. Three species are figured in Blackwall's *Spid. Great Britain and Ireland*, pl. xii.; two of them prey upon *Agroëca brunnea* (Bl.); while the third, *Pompilus sepicola* (F. Smith), pierces large spiders, paralysing, but not killing them; they are then dragged to its nest, in a hole in the earth; eggs are laid in the spider, which retains sufficient vitality to furnish fresh food to the parasitic larvæ until the time for their change to the pupa state arrives. Full grown females of *Lycosa campestris* (Bl.) have been found by the writer in the grasp of this powerful ichneumon. From the outskirts of a single web of *Epeïra opuntiæ* (Duf.), on the shores of the Sea of Galilee, the writer collected, in April 1865, many truncated pear-shaped egg cocoons belonging to the beautiful little *Argyrodes epeïræ* (Sim.); and from each of these cocoons a single hymenopterous parasite shortly issued. The egg cocoons of various epeïrids in England are likewise often preyed upon by numerous minute parasites of the same order. Several species of *Theridion*—*T. simile* (Koch) especially—are subject to a larval parasite, often as large as the spider itself, adhering to the outside of the abdomen. Various attempts to rear the perfect insect from this parasite have hitherto failed. A wide field of great interest is open to any one who should take up the investigation of the various insect parasites of spiders, with their mode of attack and subsequent victory.

Other foes, common to all the Articulata, spiders also have in abundance—birds, small mammals, and reptiles. Doubtless we are indebted to such enemies for the development, through natural selection, of many spiders protected by horny integuments, and often armed with spines to an extent that would make them a painful meal to any bird or other creature that should set itself to dine upon them. *Phoroncidia Thwaitesii* (Cambr.), found in Ceylon, and *Pycnacantha Meadii* (Bl.), found in Africa, and indeed all the Gasteracanthides, are notable examples of this protective armature. *Protective "mimicry"* is also seen in spiders, some so exactly resembling ants, that placed side by side with species of ants found in the same localities, even a practised eye would not detect the spider at first sight. Of this nature are the *Myrmecides* (fig. 31) and some of the *Saltici*, and, notably, *Aphantochilus*

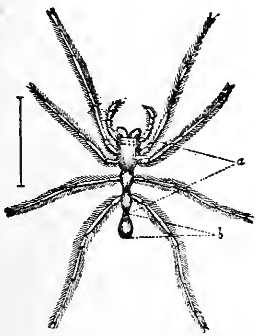

FIG. 31.—Ant-spider (*Myrmecia fulva*, Latreille). *a*, cephalo-thorax; *b*, abdomen.

Rogersii (Cambr.), found in Brazil. Other spiders, again (Genus *Eurysoma*, Koch, and *Cyrtarachne*, Thor.), closely resemble some species of phytophagous coleoptera; one of the latter genus found in Ceylon, but yet undescribed, resembles a small mollusc. Of the former some are very like a minute crab (fig. 32). And lastly, to sum up the enemies of spiders, they prey on each other, and are preyed upon also by other Arachnids; but on the whole they have, as by their office they should have, the best of it, for they are against *all* the Articulata, but only comparatively a *few* of the Articulata are against them.

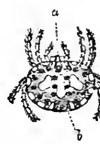

FIG. 32.—Crab-spider (*Eurysoma cabindæ*, Capello). *a*, cephalothorax; *b*, abdomen.

Spiders are not creatures which belong solely to the present geologic era of the earth, for fossil spiders, with other Arachnids, as well as spiders in amber, have been found; the oldest in the coal formation. See on this subject a late resumé by Dr T. Thorell, *On European Spiders*, pp. 220-233, with other works there quoted.

PRESERVATION OF SPIDERS.—Beautiful as are the colours and markings of numbers of spiders, especially of those found in the tropics, and elegant and curious as are many of their forms and structures, it has yet been found a matter of difficulty to make them good-looking, sightly, cabinet objects. By ordinary care and skilful manipulation, however, most of them can be preserved and displayed very satisfactorily. So much of the comparative neglect of Arachnids in general is owing to this difficulty, that it may perhaps be worth the space of a few lines to remark, that many whose abdominal integument is strong, or pretty thickly clothed with hairs and pubescence, may be pinned, set out, and dried like insects. Others may have the abdomen opened from below, and after the contents are carefully extracted, be stuffed with fine cotton wool. Others again have been most successfully treated by inflating the abdomen (after the contents have been pressed out) with a blow-pipe, and then subjecting them to a process of rapid desiccation, which in general preserves the colours and markings very well indeed. But the best and most useful way for *all* purposes is to immerse and keep them in tubes filled with spirit of wine. To make spiders in spirit sightly objects, they should, when drugged with chloroform, or some other stupifying agent, be secured, but not transfixed, by pins to a piece of cork, sunk in a vessel of spirit, in a natural position, until rendered rigid by the action of the spirit, which will be in a fortnight or so; the pins are then removed, and the spiders are placed in glass test tubes, large enough to receive them without too much compression of the legs. A bit of white card is slipped in under the specimen to keep it in position, the tubes are filled with spirit, stopped firmly with a pledget of cotton wool, and inverted round the inner side of a wide mouthed glass-stoppered bottle; this bottle is filled also with spirit, and the spider is then seen in its natural position, and with all its colours and markings perfectly visible. It is also capable of examination with an ordinary pocket lens, even without removal of the tube from the large bottle. Large spiders with a largely developed abdomen should be kept in pill-boxes for a fortnight or so before being placed in spirit; during this time the crudities of their food contents are discharged, and preservation without injury or obliteration of colours and markings is thus rendered far more certain; the beauty of many of our large and handsome epeïrids can only be certainly retained, even in spirit, when treated after the above method. See further on this subject, as well as on the mode of search and capture of spiders (O. P. Cambridge, *Trans. New Zeal. Instit.*, vol. vi. pp. 194-200).

It is not necessary to give here a list of works on Arachnids, many having been already quoted in speaking of the different orders. The following, however, on *Araneidea* may be mentioned:—

N. Westring, "*Araneæ suecicæ*," Gothenburg, 1861; E. Ohlert, *Die Araneiden oder Echten Spinnen der Provinz Preussen*, Leipzig, 1867; A. Menge, "Preussiche Spinnen," in *Schr. Ges. Danz.* (*N. F.*), 1866-1873, Danzig (still in course of publication); H. Lucas, in *Exploration de l'Algérie*, Paris, 1849; H. Nicolet, in Gay's *Hist. Fis. Pol. de Chili*, vols iii.-iv., Paris, 1847; Eugene Simon, *Les Arachnides de France* (vol. i. only is yet published), Paris, 1874; L. Koch, *Die Arachniden Australiens*, Nuremberg, 1871-74 (still in continuation). Nothing has been said in the foregoing pages respecting the "Embryology" of spiders; for information in regard to this important and interesting but recondite part of Araneology, it must suffice to refer the reader to Herold, *De Generatione Aranearum in Ovo*, Marburg, 1824, and Edouard Claparède, *Recherches sur l'evolution des Araignées*, Utrecht, 1862.

These, with other works quoted on the different points that have arisen in the course of the foregoing article, will be found sufficient to guide the student and collector. The general works on Arachnida, or on any of its separate orders, are exceedingly few, and none, except that of M. Simon, *Hist. des Araignées*, Paris, 1864, are of recent date, beyond the merest abstracts. The literature on the subject is scattered up and down, in isolated papers, in numberless Transactions and Proceedings of various societies, and in scores of periodical volumes and journals for the record of natural and scientific investigation. It has been attempted to give in the foregoing pages as fair a general view of the whole subject as the limited space, and great difficulty of getting access to important papers treating upon it, would permit. The object of such articles as the present is rather to *excite* an appetite for the obtaining more detailed information, than to satisfy fully the appetite already excited. (O. P. C.)

ARAD, Old, a city of Hungary, in the county of Arad, situated on the Maros, 145 miles S.E. of Pesth. It is a well-built town, with a fortress of considerable strength, erected in 1763, which occupies an advantageous position between two branches of the river. It is the seat of a Greek bishop, and has a Greek theological seminary. Its chief manufacture is that of tobacco; and, besides carrying on a large trade in corn, it possesses one of the most celebrated cattle fairs in Hungary. In 1849 the fortress of Arad was captured by the Hungarian rebels, who made it their head-quarters during the latter part of the insurrection. It was from it that Kossuth issued his famous proclamation, and it was here that he handed over the supreme military and civil power to Görgey. The fortress was recaptured shortly after the surrender of Görgey to the Russians at Vilagos. The population of Old Arad is 32,725, many of whom are Jews, while many belong to the Greek Church. New Arad, situated on the left bank of the Maros, opposite to Old Arad, is a place of some trade, with a population of about 4000, including many Germans.

ARAFAT, or Orphat, a mountain near Mecca, a visit to which constitutes a necessary part of the great Mahometan pilgrimage. (See Mecca.) It consists of a granite rock about 200 feet high, which is ascended by staircases partly cut in the rock, and partly composed of solid masonry. On this hill Adam is said to have met his wife Eve after being separated from her for 120 years, and it is thence called Arafat, *i.e.*, Gratitude. On the summit is a chapel, which the Mahometans believe to have been built by Adam. The interior was destroyed in 1807.

ARAGO, François Jean Dominique, one of the most popular physicists belonging to the first half of the present century, was born on the 26th February 1786, at Estagel, a small village near Perpignan, in the department of the Eastern Pyrenees. His father was a licentiate in law, and, being appointed treasurer of the mint for the department, removed with his family to Perpignan about the beginning of the century. Arago has left an autobiographical sketch, drawn with great vivacity, though touched occasionally with somewhat high colouring; and to this we are indebted for the incidents of the earlier portion of his life. From boyhood he had decided military tastes, inspired by constant contact with troops at his native village, which was a halting station for soldiers on their way to Perpignan, or to the army of the Pyrenees. François was sent as an out-door pupil to the municipal college of Perpignan, and began to study mathematics with an eye to the entrance examination to the Polytechnic school. Here he was soon beyond the depth of his master's knowledge; but, with that undaunted spirit which carried him through many hardships and difficulties in after life, he sent to Paris for the works of Legendre, Lacroix, and Garnier, and studied them assiduously in private. Within two years and a half he had mastered all the subjects prescribed for examination, and a great deal more; he had read Euler's *Introduction à l'Analyse Infinitesimale*, Lagrange's *Théorie des Fonctions Analytiques* and *Mécanique Analytique*, and Laplace's *Mécanique Céleste*. He does not indeed pretend to have understood at the time all he read in these works, but he had been early encouraged by D'Alembert's maxim, "Go on, and the light will come to you," and he had carried it into practice. On going up for examination at Toulouse he completely astounded his examiner, M. Monge, by his knowledge of Lagrange, and received the highest commendation from him. Towards the close of 1803 he entered the Polytechnic school, with the artillery service as the aim of his ambition. We have in the autobiography many amusing instances of the inefficiency of some of the Polytechnic professors at that time, of the peculiarly French familiarity existing between professors and pupils, as well as of the political passions absurdly allowed to distract the school. In 1804, through the advice and recommendation of Poisson, with whom he had become very intimate, Arago received the appointment of secretary to the Observatory of Paris, a valuable post for a young man of science, as it brought him in contact with the most eminent philosophers of the day. He now became acquainted with Laplace, and he had as fellow-worker in the laboratory the celebrated Biot. Through the influence of Laplace with the Government, Arago and Biot were commissioned to complete the meridional measurements which had been begun by Delambre, and interrupted since the death of Méchain in 1804. The object of this survey was to determine, with as great nicety as possible, the ten-millionth part of a quadrant of the meridian through Paris, which had been agreed upon by the National Convention as the standard unit of length, and named the *mètre*. To measure an actual quadrant from the north pole was, of course, an impossibility; but the plan adopted was to measure the arc of the meridian from Dunkirk to Barcelona, and from their known difference of latitude to deduce the length of the quadrant. For this purpose they left Paris in 1806, to commence operations among the mountains of Spain—operations attended with the greatest personal privation, fatigue, and danger. Biot returned to Paris after they had determined the latitude of Formentera, the southernmost point to which they were to carry the survey, leaving Arago to make the geodetical connection of Majorca with Ivica and with Formentera.

The adventures and difficulties of the latter were now only beginning. The political ferment caused by the entrance of the French into Spain extended to these islands, and the ignorant populace began to suspect that Arago's movements and his blazing fires on the top of Mount Galatzo were telegraphic signals to the invading army. They became ultimately so infuriated that he was obliged to cause himself to be incarcerated in the fortress of Belver in June 1808. On the 28th July he managed to escape from the island in a fishing boat, and after an adventurous voyage he reached Algiers on the 3d August. Under the disguise of a strolling merchant he procured a passage in a vessel bound for Marseilles. A journey, however, of eleven months was before him ere he was destined to reach that port, for the vessel fell into the hands of a Spanish corsair on the 16th August, just as it was nearing Marseilles. With the rest of the crew, Arago was taken to Rosas, and imprisoned first in a windmill, and afterwards in the fortress of that seaport, until the town fell into the hands of the French, when the prisoners were transferred to Palamos. After fully three months' imprisonment they were released on the demand of the Dey of Algiers, and again set sail for Marseilles on the 28th Nov., but when within sight of their port they were driven back by a southerly wind to Bougia on the coast of Africa. Transport to Algiers by sea from this place would have occasioned a weary stay of three months; and with his usual courage, Arago set out for it by land under conduct of a Mahometan priest, reaching it on Christmas day, after encountering many perils from lions, and having uncomfortable squabbles with natives on the way. A six months' stay in Algiers gave him opportunity to note the manners and habits of the people, of which he gives some amusing and graphic accounts. Once again, 21st June 1809, he set sail for his native land; and, as by some strange perversity of fortune, he had to undergo a monotonous and inhospitable quarantine in the Lazaretto at Marseilles before his difficulties were over. The first letter he received, while in the Lazaretto, was from Humboldt at Paris, sympathising with him, and congratulating him on the termination of his laborious and perilous enterprise; and this was the origin of a connection which, in Arago's words, "lasted over forty years without a single cloud ever having troubled it."

Through all the vicissitudes of this long campaign Arago had succeeded in preserving the records of his survey; and his first act on his return home was to deposit them in the Bureau de Longitude at Paris. As a reward for his adventurous conduct in the cause of science, he was shortly afterwards (17th Sept. 1809) voted a member of the Academy of Sciences, in room of the deceased Lalande, at the remarkably early age of twenty-three, being, to the vexation of Laplace, elected by a large majority of votes over his friend Poisson. Before the close of the same year (1809) Arago was chosen by the council of the Polytechnic school to succeed M. Monge in the chair of analytical geometry; and about the same time he was named by the emperor one of the astronomers of the Royal Observatory, which was accordingly his residence till his death. He was also made one of the examiners in connection with the *Ecole d'Application* for engineers and artillery at Metz. In all these situations he rapidly attained very great popularity, gaining the esteem of his pupils by the charming clearness of his style in lecturing and the personal interest he showed in their progress.

In 1816, along with Gay-Lussac, Arago commenced a monthly journal of science, the *Annales de Chimie et de Physique*, which soon acquired that high scientific reputation which it has always maintained. In the same year the two philosophers visited England, and made the personal acquaintance of some of the most eminent men of that country, meeting among others Dr Thomas Young, a memoir of whom was afterwards written by Arago. In 1818 or 1819, Arago proceeded along with Biot to execute, on the coasts of France, England, and Scotland, the geodetic operations which the Board of Longitude had directed. They also measured the length of the seconds' pendulum at Leith, and in Unst, one of the Shetland isles; the results of the observations being published in 1821, along with those made in Spain. He was elected a member of the Board of Longitude immediately afterwards, and proved a valuable addition to the society, contributing to each of its *Annuals*, for about twenty-two years, most important scientific notices on astronomy and meteorology, and occasionally on civil engineering, as well as interesting memoirs of members of the Academy.

After his appointment to the Observatory, Arago had commenced, at the request of the Board of Longitude, a series of popular lectures on astronomy, which were continued from 1812 to 1845. His success as a lecturer was almost unparalleled, and can only be compared to that of Faraday. All ranks flocked to hear him, fascinated by his graceful eloquence and his crystalline clearness of explanation. He used to remark, what many lecturers often forget, that "*clearness is politeness in public speakers.*" His manner in lecturing is said to have been to fix his eye on some one of his audience, whose intellect had apparently the minimum of development, and to keep it fixed till the face should brighten up with intelligence.

When Buonaparte's hopes of empire in Europe had begun to wane, and he was turning to America as a land of refuge, where he might still have scope for his ambition, he suggested to M. Monge that, with a scientific guide, he should explore the new continent from Canada to Cape Horn, study the great physical wonders of that territory, and leave behind him works and discoveries worthy of himself. Monge named Arago as the proper associate and assistant in the enterprise, and had even negotiated with Napoleon for a handsome allowance to be granted to Arago, and for a fund to be devoted to the purchase of a complete set of astronomical and physical instruments. But Arago would not for a moment entertain the proposal. He pointed the emperor to the march of the English and Prussian armies on his capital as a matter demanding more pressing consideration, and declined to leave the Old World to study science in the New, "when France might perhaps lose its independence and disappear from the map of Europe." Subsequent events prevented a renewal of Napoleon's scientific negotiations and projects.

After the Restoration Arago took no very prominent part in the politics of the day, though he at all times maintained with boldness and ardour liberal opinions of the extreme republican type. By the revolution of 1830, however, he was summoned from the studies of the observatory and the laboratory to the field of political strife in the Chamber of Deputies, and in the Municipal Council of Paris. Elected a member of the Chamber of Deputies for the Lower Seine, he employed his splendid gifts of eloquence and scientific knowledge in all questions connected with public education, the rewards of inventors, and the encouragement of the mechanical and practical sciences. Many of the most creditable national enterprises, dating from this period, are due to the advocacy of Arago—such as the reward to Daguerre for his wonderful invention of photography, the grant for the publication of the works of Fermat and Laplace, the acquisition of the museum of Cluny (one of the sights of Paris), the development of railroads and electric telegraphs, the improvement of the navigation of the Seine, and the boring of the Artesian wells at Grenelle.

The year 1830 was a remarkable epoch in his life on account of several other offices to which he was appointed. He now received the chief direction of the Observatory, and from his position in the Chamber of Deputies he obtained grants of money for the rebuilding of part of the Observatory and for the addition of magnificent instruments, which raised it to be a model, in place of a public disgrace, as it had been before. In the same year, too, his zeal in the cause of science was rewarded with the highest honour any philosopher might aspire to—the perpetual secretaryship of the Academy of Sciences, in room of the distinguished Fourier. On the 7th June (1830) he was elected by 39 out of 44 votes. This appointment inspired new life into the Academy. Arago threw his whole soul into its service, and by his pleasing faculty of securing friendship and life-long attachments, he gained at once for himself and for the Academy a world-wide reputation. As perpetual secretary it fell to him to pronounce historical *éloges* on the decease of resident or foreign members of the Academy; and for this duty his rapidity and facility of thought, his happy piquancy of style, and his extensive knowledge peculiarly adapted him. Some of his *éloges* are masterpieces of elegant biography. When M. Flourens pronounced Arago's own funeral eulogy, he said, "In the eulogies of the eloquent secretary are found all the qualities of his spirit, *d'une verve brillante, de la vigueur, de l'elan, un certain charme de bonhomie.*"—(*Comptes Rendus de l'Academie*, t. xxxvii. p. 513.)

In 1834 Arago visited England for the second time, to attend the third meeting of the British Association, held that year in Edinburgh. From this time till the stirring events of 1848, Arago led a life of comparative quiet,—not the quiet of inactivity, however, for his incessant labours within the Academy and the Observatory produced a multitude of contributions to all departments of physical science, which make him one of the most voluminous of authors in this subject. But the change came. Louis Philippe, having failed to satisfy the extreme republican party, and to grant them those social advanteges that they imagined a republic alone could yield, was swept from his throne, and Arago left his laboratory to join in forming an extempore government. His popularity was so great that he was entrusted with the discharge of two most important functions, that had never before been united in one person, viz., the Ministry of War and of Marine. Energetically and faithfully the philosopher of forty years' standing applied himself to his new duties; and however ignominious may have been the ultimate failure of the Provisional Government, there can be little question that Arago struggled honestly in the cause of social liberty and improvement. While Minister of Marine he effected some salutary reforms, such as the improvement of rations in the navy and the abolition of flogging; he abolished political oaths of all kinds, and, against an array of monied interests, he succeeded in procuring the abolition of negro slavery in the colonies.

During the insurrection of June, Arago's courage was conspicuously displayed in his entreaties to the mob to stop their murderous outrages. For the first time in his life Arago failed, and he himself narrowly escaped with his life. With his mental and physical energies shattered by fatigue and disappointment, he terminated here his active political career, though he continued to the last to take an interest in the affairs of his country, and to watch for the dawn of a brighter future. Failing eye and trembling hand could now be of little use in the service of science; but warned by the disease (diabetes) that had attacked him, he determined to occupy his few remaining years in preparing for the press some MSS. of original researches which his political duties had prevented his communicating to the Institute.

In the beginning of May 1852 proclamation was made that the oath of allegiance to the Government of Louis Napoleon would be required from all its functionaries, including the Board of Longitude. Arago peremptorily refused, choosing to sacrifice his office and home of nearly half a century rather than violate the dictates of his conscience, which he would be doing if he complied, seeing that, as a member of the Provisional Government of 1848, he contributed to the abolition of all political oaths. In a letter to the Minister of Public Instruction, he intimated his resignation of his post as astronomer at the Bureau de Longitude, at the same time stating the services he had rendered to his country in the cause of science, and the grief which this separation from the scene of his labours of so many years would impose. To the credit of the Prince President, he respected the sentiments so boldly declared by the half-blind old philosopher, and made "an exception in favour of a savant whose works had thrown lustre on France, and whose existence his Government would regret to embitter."

The tenure of office thus granted did not prove of long duration. Arago was now on his death-bed, under a complication of diseases, induced, no doubt, by the hardships and labours of his earlier years. In the summer of 1853 he was advised by his physicians to try the effect of his native air, and he accordingly set out for the Eastern Pyrenees, accompanied by his affectionate niece, Madame Langier. But the change was unavailing, and he returned to Paris to die. After a lingering illness, in which he suffered first from diabetes, then from Bright's disease, and lastly from dropsy, he breathed his last on the 2d Oct. 1853, at the age of 67. The day before his death he had been visited by Lord Brougham, his old and intimate friend, and the interview had excited him much. M. Biot also had an interview with him only three hours before his death. Arago said to his veteran colleague and *collaborateur*, "I intend to resign my situation of perpetual secretary to the Academy, since I can no longer discharge its duties." Biot's reply must have smoothed the pillow of the dying savant, "If you do, we will all come to you in a body to bring it back to you, and reproach you for your ingratitude." A public funeral was, with good taste, decreed to Arago by the emperor, notwithstanding his refused allegiance to the Imperial Government, and it took place on the 5th Oct. with all the pomp and parade of an Imperial act. A beautiful and eloquent eulogy was pronounced over his tomb by the distinguished M. Flourens, who succeeded him as perpetual secretary of the Academy, while M. Barral performed the duty entrusted to him by the young philosophers of the public schools of the metropolis of giving utterance to their last adieu.

Thus closed perhaps the most singular career in the annals of science. Of Arago's moral character it is difficult to form a true estimate, extolled as it is on the one side by his countrymen, and too severely criticised as it often is on the other side by British writers. Allowance must be made for the Spanish blood that flowed in his veins. The ardour of his temperament, his quick and far darting intellect, the powerful love of country which his youthful vicissitudes had only intensified, all combined to produce a consciousness of power, which, in the Academy of Sciences or in the management of the Observatory, might stamp his bearing as dictatorial, and which, in questions of national priority of invention, might render his judgment partial. With the imperiousness, perhaps, of a powerful intellect, Arago was free from that selfishness that has so often been exhibited by men who have enjoyed such high offices of trust during times of national disorder. He cared for money only as it supplied the wants of his experimental researches and the means of educating his family; he lived a simple and a frugal life; his income never exceeded £500 a year; and, refusing to accept any reward for his four months' services as Minister of Marine, he sacrificed fortune for the sake of his country and of science.

From the personal history of Arago we turn to his literary and scientific labours and discoveries. It has been already shown that, as editor of the ***Annuaire*** or Almanac of the Board of Longitude, he commenced, in 1822, a series of regular contributions of scientific articles to that Annual, remarkable for their lucidity of style, united with mathematical accuracy of detail; that, as perpetual secretary of the Academy of Sciences, his *éloges* alone would have secured him lasting reputation; and that, as director of the Observatory, he rapidly restored its efficiency and completely remodelled it. He has, indeed, been often accused of doing little or nothing for the practical advancement of astronomy; and of shrinking from the steady and regular drudgery of observation as too tame to be congenial to his versatile mind. To reproach a man who has done much, because he has not done more, or because he has not followed in the beaten track, is, to say the least, far from generous criticism. His applications of physics to astronomical research—such as to his photometric measurements of lunar and stellar brightness, of the polar snows of Mars, and of the belts of Jupiter and Saturn, to the structure of the sun as revealed by his spots, to the effect of atmospheric refraction on astronomical observations, to irradiation and variable stars—are surely in themselves not despicable contributions to the science. But apart altogether from his labours in the Observatory, he has rendered vastly greater service to astronomy by his popular expositions of it than hundreds of the most assiduous observers put together. Few have had, in such a degree as he, the gift of reducing the abstract conceptions of pure science to the level of the popular apprehension without descending to the puerile and frivolous.

In 1820, when the subject of steam boilers was attracting attention, Arago was employed by Government to execute, along with Dulong, a series of experiments on the elastic force of steam at different temperatures. This difficult and most hazardous task, where they were exposed to the bursting of a boiler at any moment, they accomplished with the greatest ability and coolness. Of these experiments, as well as of others,—on the density of air, on the velocity of sound, on the pressure of gases being proportional to their density, &c.,—there will be found elaborate memoirs in the *Comptes Rendus* of the Academy, and in the *Annales de Chimie et de Physique.*

It is, however, on his contributions to Magnetism and Optics that Arago's fame as an experimenter and discoverer rests. By employing the method of oscillating needles, he established the universal influence of magnetism on all substances, though it was left to Faraday to make the grander generalisations of diamagnetism. Arago found that a magnetic needle, made to oscillate over non-ferruginous surfaces, such as water, glass, copper, &c., falls more rapidly in the extent of its oscillations according as it is more or less approached to the surface. Over ice, for example, an oscillation of 53° on each side of the magnetic meridian, fell to 43° after 60 oscillations at a distance of $52\frac{1}{2}$ millimetres from the ice; while, at a distance of 7 mm., it fell by the same amount after 26 oscillations. Over glass there was a fall from 90° to 41° in 221 oscillations, at a distance of 4·01 mm., and in 122 oscillations at a distance of ·91 mm. For this discovery Arago was awarded the Copley medal by the Royal Society of London in 1825; and he has the honour of being the first foreigner to whom this distinction was accorded. This discovery was followed by another. It occurred to him to try, conversely, the effect of oscillating or rotating a plate of non-ferruginous metal near a magnetic needle at rest. He caused a plate of pure copper to revolve by clock-work, which was also of copper, under a magnetic needle within a glass-receiver, and with a sheet of paper between the needle and the revolving plate to prevent air currents. Gradually the needle was drawn from the magnetic meridian, till finally, on a very rapid rotation of the plate, it fairly swung round and continued in constant rotation. An account of these experiments he read before the Academy of Sciences, on the 7th March 1825, and they were exhibited in London in the following April by Gay-Lussac, exciting universal interest among the philosophers of this and other countries. This phenomenon of *rotatory magnetism,* as it is termed, is indissolubly linked with the name of Arago; but it was reserved for the genius of Faraday to offer the true explanation of it, after it had long occupied the attention of Herschel, Babbage, Barlow, Nobili, and other distinguished men, as well as of its discoverer.

Arago is also fairly entitled to be regarded as having proved the long suspected connection between the aurora borealis and the variations of the magnetic elements. He established, too, the fact of an hourly variation of these, traceable, no doubt, to the influence of the sun as an enormous magnet at a distance. It is worth mentioning that Arago was the first to employ the galvanic current for the permanent magnetisation of steel, though in the field of electro-magnetism his discoveries and researches as a whole are not to be compared with those of the profounder Ampère.

It is, however, his investigations in Optics that form the most marked feature and the crowning glory of Arago's scientific career. We owe to him not only important optical discoveries of his own, but the credit of stimulating the genius of Fresnel, with whose history, as well as with that of Malus and of Young, this part of his life is closely interwoven. Shortly after the beginning of the present century the labours of the three philosophers last named were shaping the modern doctrine of the undulatory theory of light. Malus had made in 1808 his discovery of the polarisation of light by reflection, identifying it with the effects of double refraction; Young had devised his beautiful theory of interferences; and Fresnel had been simultaneously conducting elegant experiments in the very same field as the English philosopher. It was the communication to the French Academy of Sciences of a paper on this subject by Fresnel that led to his intimacy with Arago. Fresnel's arguments in favour of the undulatory doctrine found little favour with Laplace, Poisson, and Biot, the champions of the emission theory; but they were ardently espoused by Humboldt and by Arago, who had been appointed by the Academy to report on the paper. This was the foundation of an intimate friendship between Arago and Fresnel, and of a determination to carry on together further researches in this subject. These investigations were rewarded by a remarkable discovery, in 1811, the very year that Malus terminated his career so auspiciously begun. After Huyghens's time, when Iceland spar and rock crystal were alone supposed to have the property of double refraction, mineralogists had suspected the same property to exist in a number of other crystals, though it was often almost impossible to determine its existence. But Arago discovered that a plate of any doubly refracting crystal, such as selenite or mica, when interposed between two similar polarising prisms or piles of glass plates, displays splendid tints, varying in colour with the thickness of the plate and with its inclination to the transmitted beam, and varying in intensity as the plate of mica or selenite is turned round in its own plane. By this simple means double refraction may be detected in the smallest plate of a crystal. The explanation of this remarkable phenomenon was a difficult problem, and for some time perplexed both English and Continental investigators. Dr Young, in 1814, ascribed the cause generally to interference; but Arago saw that this explanation was incomplete. The clue to it was, however, found in the law, established by the joint labours of Arago and Fresnel, *that two polarised rays cannot interfere unless polarised in the same or parallel planes.* This involved the idea of *transverse vibrations* of the ether across the direction of propagation, an idea which at first seemed a stumbling-block to the theory of undulations, and which Fresnel and Arago did not venture for some time to embrace. Once expressed, however, this theory of transverse vibrations reduced the whole phenomena of polarisation to a simple mechanical effect, a *resolution of rectilinear motion into two rectangular components;* and so far from upsetting the wave theory, it has by its very simplicity and comprehensiveness but helped to establish it on a sure foundation.

Arago applied his discovery to the construction of a *polariscope,* for estimating the feeblest amount of polarisation; and he used this instrument for some very interesting experiments on the polarisation of the light of the sky (which is sunlight polarised by reflection from the atmosphere), and on that of different incandescent and reflecting surfaces. He also found that the moon and the tails of comets send light to the eye which is slightly polarised, thus betraying its borrowed origin. But that of the sun, being absolutely neutral, is only comparable (according to Arago) to the light arising from incandescent vapours, thus distinguishing the sun from a solid or liquid globe.

We cannot do more than allude to Arago's other optical papers and experiments. He was, probably, the only Frenchman of his time who was well acquainted with Young's discoveries. The explanation by the doctrine of interference of the colours of Newton's rings received an important confirmation from an experiment of Arago's, which proved them to arise from the mixture of the pencils of light reflected at the two neighbouring surfaces. He pressed a lens of glass against a plate of metal, in which case the central spot is white or black when light polarised perpendicularly to the plane of incidence is reflected at an angle greater or less than the polarising angle for glass; and the rings vanish altogether at the polarising angle — results which Airy subsequently proved conformable to the undulatory theory.

To Arago is also due the discovery of the power of *rotatory polarisation* exhibited by quartz. He found that a beam of polarised light transmitted along the axis of a crystal of quartz becomes depolarised, and produces colours varying with the thickness of the crystal. If the polarised light be homogeneous, and the analysing plate be placed athwart this polarised beam so as to reflect none of it, the interposing of a quartz crystal will turn round the polarised beam in its passage, so that when it falls on the analysing plate it is no longer athwart it, and the light is partly reflected. The researches in this field were taken up by Biot, Fresnel, Herschel, Seebeck, Airy, and others; and the phenomenon was first explained by Airy to be due to the fact that along the axis of a quartz crystal the beam consists of two circularly polarised portions, while in other directions it consists of two elliptically polarised portions. In some substances the rotation is to the right hand, and in others to the left.

Last of all, among the many contributions of Arago to the support of the undulatory hypothesis, comes the *experimentum crucis* which he proposed to carry out for comparing directly the velocity of light in air and in water or glass. On the emission theory the velocity should be accelerated by an increase of density in the medium; on the wave theory, it should be retarded. Wheatstone's experiment, in 1835, of measuring the velocity of the electric discharge had suggested the idea to Arago; and in 1838 he communicated to the Academy the details of his apparatus. Owing to the great care required in the carrying out of the project, and to the interruptions to his labours by the events of the revolution, it was the spring of 1850 before he was ready to put his idea to the test. But, as fate would have it, just at that time his eye-sight suddenly gave way. With a melancholy resignation he consoled himself with having merely laid down the problem and having indicated the means of its solution, and with the hope that other experimenters would follow in his steps and add a new proof in favour of the undulatory system. Arago lived to see his wishes realised in the beautiful experiments of Fizeau and Foucault, which, with improvements of detail in the apparatus, were based on the plan proposed by him. These, as all the scientific world knows, confirmed the deductions from the wave theory, and established the retardation of the velocity of light in denser media. With this ended those brilliant labours which have in no small degree contributed to render the arguments in favour of the undulatory doctrine all but unanswerable.

Arago's *Œuvres* were published after his death under the direction of M. J. A. Barral, in 17 vols., 8vo, 1854 to 1862; also separately his *Astronomie populaire*, in 4 vols.; *Notices biographiques*, in 3 vols.; *Notices scientifiques*, in 5 vols.; *Voyages scientifiques*, 1 vol.; *Mémoires scientifiques*, in 2 vols.; *Melanges* (Miscellanies), in 1 vol., and *Tables analytiques et documents importants* (with portrait), in 1 vol. English translations of the following portions of his works have appeared:—*Treatise on Comets*, by C. Gold, C.B., London, 1833; also translated by Smyth and Grant, London, 1861; *Hist. éloge of James Watt*, by James Muirhead, London, 1839; also translated, with notes, by Lord Brougham; *Popular Lectures on Astronomy*, by Walter Kelly and Rev. L. Tomlinson, London, 1854; also translated by Dr W. H. Smyth and Prof. R. Grant, 2 vols., London, 1855, *Arago's Autobiography*, translated by the Rev. Baden Powell, London, 1855, 1858; *Arago's Meteorological Essays*, with introduction by Humboldt, translated under the superintendence of Colonel Sabine, London, 1855; and *Arago's Biographies of Scientific Men*, translated by Smyth, Powell, and Grant, 8vo, London, 1857.

ARAGON, a captaincy general, or, as it is usually called by the Spaniards, a kingdom, of Spain, situated between lat. 40° and 42° 51′ N., and between long. 2° 10′ W. and 1° 45′ E., is bounded on the N. by the Pyrenees, which separate it from France, E. by Catalonia and Valencia, S. by Valencia, and W. by Navarre and the two Castiles. It has an area of 14,726 English square miles, and a population of 925,773—calculated for 1867 on the basis of the census of 1860. It is divided by the river Ebro, which flows through it in a south-easterly direction, into two nearly equal parts, known as *Trans-ibero* and *Cis-ibero*. The north is occupied by a portion of the Pyrenees, which here attain in Monte Perdido, or as it is variously called Mont Perdu, Las Tres Sorores, almost their highest altitude (11,430 feet); and in the south and west are various sierras of considerable elevation. The whole surface, indeed, is very irregular. The large and fertile plain in the middle, bordering on the Ebro, is broken by offshoots from the north and south, while the mountain ranges, on the other hand, are interrupted by numerous valleys of great beauty. The central pass for carriages over the Pyrenees is on the line between Saragossa and Pau, and bears the name of Port de Confranc. The Ebro is the principal river, and receives from the north in its passage through the province, the Arba, the Gallego, and the united waters of the Cinca, the Essera, the Noguera Ribagorzana, and the Noguera Pallaresa—the last two belonging to Catalonia; and from the south the Xalon and Xiloca and the Guadalupe. The Imperial Canal of Aragon, which was commenced by Charles V. in 1529, but remained unfinished for nearly two hundred years, extends from Tudela almost to Sastago, a distance of 80 miles; it has a depth of 9 feet, and an average breadth of 69, and is navigable for vessels of about 80 tons burthen. The Royal Canal of Tauste, which lies along the north side of the Ebro, was cut for purposes of irrigation, and gives fertility to the district. Two leagues N.N.E. of Albarracin is the remarkable fountain called Cella, 3700 feet above the sea, which forms the source of the Xiloca; and between this river, and the Sierra Molina is an extensive lake called Gallocanta, covering about 6000 acres. The climate of Aragon is, as might be supposed, of a very varied character, rigorous in the north and among the sierras, but mild and even oppressive in the south, especially towards the Mediterranean. Its vegetable products are necessarily affected by a similar variety. The hills are clothed in many places with oak, pine, and beech, which, if utilised, would furnish a good supply of timber. The flora is exceedingly rich, but has been slightly explored. Wheat, maize, rice, wine, oil, flax, and hemp, of fine quality, are grown in considerable quantities; as well as saffron, madder, liquorice, sumach, and a variety of fruits. Swine and sheep are reared in considerable numbers, the merino wool supplied by the latter being one of the chief productions of the province; but little attention is paid to other descriptions of cattle. The manufactures are comparatively insignificant, being in great measure supplementary to the agricultural and pastoral pursuits of the people. The silk manufacture has declined, and woollen and linen cloth is only produced in small quantities. The mineral resources of the country consist of iron, lead, copper, sulphur, cobalt, asphalt, lignite, alum, rocksalt, jet, marble, and jasper, which are all found in abundance, but they are very inadequately wrought. Aragon is divided into three provinces, HUESCA, TERUEL, and SARAGOSSA, accounts of which will be found under these headings. The capital is Saragossa, and the other towns of importance are Jaca, Huesca, and Barbastro to the north of the Ebro, and Tarazona, Calatayud, Daroca, Calamocha, Albarracin, Montalban, Teruel, and Alcañiz to the south. Saragossa is an archbishopric, and Huesca, Tarazona, Barbastro, Jaca, Teruel, and Albarracin are episcopal sees. In 1867 there were 2257 priests in the kingdom.

Previous to the reign of Ferdinand and Isabella the political constitution of Aragon was the most liberal in Europe. Formally monarchical, its genius and maxims were purely republican. The kings, who were long elective, retained only the shadow of power; while the real exercise of it was in the hands of the Cortes, an assembly consisting of the nobility, the equestrian order, the representatives of the cities and towns, and the clergy. No law could pass without the assent of every member who had a right to vote. Without the permission of the Cortes, no tax could be imposed, war could not be declared, nor peace concluded. Besides these, and other extraordinary privileges enjoyed by the Cortes, the Aragonese possessed another safeguard against despotic power in the election of a *Justicia*, or supreme judge, who acted as the guardian of the people, and the controller of the prince. He was the supreme interpreter of the laws, and was accountable to the Cortes alone for the manner in which he discharged the duties of his office. See Robertson's *History of Charles V.*, vol. i. § 3.

The history of Aragon after its union with Castile by the marriage of Ferdinand and Isabella, when it was merged in the kingdom of Spain, will be found in the general history of that country. It had, before this epoch, a succession of twenty sovereigns, from the year 1035 to 1516. See Zurita, *Annales de Aragon; Viaje* de Ponz; *Geografia* de Don Isidoro de Antillon; *Historia de la Economia Politica de Aragon*, por Don. Ignacio de Asso.

ARAGONA, a town in Sicily, 7½ miles N.N.W. of Girgenti. It has an old castle with a fine collection of paintings and antiquities. Almonds are largely grown in the neighbourhood; and not far off is the famous mud volcano of Maccaluba. Population, 11,424.

ARAGUAYA, or ARAGUIA, a river of Brazil which rises in the Sierra Sciada, and flows north between the provinces of Matto Grosso and Goyaz till it joins the Tocantins at San Joao das duas Barras, about lat. 6° S. It divides into two branches in lat. 18° 30′, and unites again about lat. 9° 30′, thus forming the large island of Santa Anna or Bannanal. The eastern branch, called the Furo, is the one principally navigated. The most important tributaries are the Cristalino, the das Mortes, and the Caja, on the west, and the Claro, the Vermelho, the Cruxas, and the Chavantes, from the east. The whole course of the river is about 1000 miles, and it is navigable a long way up.

ARAHAL, a town in Spain, 7 miles from Seville. Situated on the level summit of a hill, it enjoys a beautiful prospect. In the wars against the Moors, it assisted the mother-city of Moron, and received its civic independence in 1555 by charter from Charles V. Its church is of Gothic architecture. The country around produces wheat, barley, beans, pease, tares, and olives. Population about 9287.

ARAKÁN, a division of British Burmah, and within the jurisdiction of the chief commissioner of that province. It consists of a strip of country running along the eastern seaboard of the Bay of Bengal, from the Náf estuary, on the borders of Chittagong, to Cape Negrais. The division is situated between 16° 2′ and 21° 33′ N. lat., and between 92° 10′ and 94° 50′ E. long. It is bounded on the N. by the Bengal district of Chittagong; on the E. by the Yumadoung mountains, which separate it from independent Burmah and the British district of Pegu; and on the S. and W. by the Bay of Bengal. Length from northern extremity to Cape Negráis, about 400 miles; greatest breadth in the northern part, 90 miles, gradually diminishing towards the south, as it is hemmed in by the Yumadoung mountains, until, in the extreme south, it tapers away to a narrow strip not more than 15 miles across. The coast is studded with islands, the most important of which are Chedubá, Ramrí, and Sháhpurá. The division has its headquarters at Akyab and consists of four districts — namely, Akyab, Northern Arákán hill tracts, Ramrí, and Sandoway. Total area estimated at 18,530 square miles, of which only 740 square miles were actually under cultivation in 1871–72. The population at the time of the British accession in 1826 did not exceed 100,000. In 1831 it amounted to 173,000; in 1839 to 248,000; and in 1871 to 461,136, or 24·9 souls per square mile. It consisted of 365,131 Buddhists, 53,289 Mahometans, 9029 Hindus, 33,337 aborigines, and 350 Christians—total, 461,136. The principal rivers of Arákán are—(1.) The Náf estuary, in the north, which forms the boundary between the division and Chittagong; (2.) the Myu river, an arm of the sea, and running a course almost parallel with the coast for about 50 miles; (3.) the Koladyne river, rising near the Blue mountain, in the extreme north-east, and falling into the Bay of Bengal a few miles south of the Myu river, is navigable by vessels of from 300 to 400 tons burden for a distance of 40 miles inland; and (4.) the Lemyu river, a considerable stream falling into the bay a few miles south of the Koladyne. Further to the south, owing to the nearness of the range which bounds Arákán on the east, the rivers are of but little importance. These are the Talak and the Aeng, navigable by boats; and the Sandoway, the Toungoop, and the Gwa streams, the latter of which alone has any importance, owing to its mouth forming a good port of call or haven for vessels of from 9 to 10 feet draught. There are several passes over the Yumadoung mountains, the easiest being that called the Aeng route, leading from the village of that name into independent Burmah. The staple crop of the province is rice, along with cotton, tobacco, sugar, hemp, and indigo. The forests produce abundance of excellent oak and teak timber. During 1871–72 the sea-borne trade of Arákán amounted to £1,345,417, the exports of rice alone being returned at £105,894. The three maritime ports of the division are Akyab, Kyoukphoo, and Sandoway; and since June 1871 steam communication has been kept up once a fortnight between all these ports and Calcutta, except in the south-west monsoon, when communication is maintained with Kyoukphoo only. The revenue of Arákán Division in 1871–72 amounted to £199,756, of which 37·29 per cent., or £74,490, was derived from the land revenue. Throughout the whole division there were only two Government and three other schools in 1870–71, attended by 251 pupils. The police force, for the protection of person and property, consisted of a total of 115 of all ranks, the proportion being one man to every 15 square miles, or one to every 385 of the population. The only town in the division with a population exceeding 5000 souls is Akyab, which has 15,281 inhabitants.

The natives of Arákán trace their history as far back as 701 A.D., and give a lineal succession of 120 native princes down to modern times. According to them, their empire had at one period far wider limits, and extended over Ava, part of China, and a portion of Bengal. This extension of their empire is not, however, corroborated by known facts in history. At different times the Mughuls and Pegus carried their arms into the heart of the country. The Portuguese, during the era of their greatness in Asia, gained a temporary establishment in Arákán; but in 1783 the province was finally conquered by the Burmese, from which period until its cession to the British in 1826, under the treaty of Yandaboo, its history forms part of that of Burmah. The old city of Arákán, formerly the capital of the province, is situated on an inferior branch of the Koladyne river. Its remoteness from the ports and harbours of the country, combined with the extreme unhealthiness of its situation, have led to its gradual decay subsequently to the formation of the comparatively recent settlement of Akyab, which place is now the chief town of the province. The old city of Arákán lies about 50 miles north-east of Akyab, in 20° 42′ N. lat., and 93° 24′ E. long. The Maghs, who form nearly the whole population of the province, follow the Buddhist doctrines, which are universally professed throughout Burmah. The priests are selected from all classes of men, and one of their chief employments is the education of children. Instruction is consequently widely diffused, and few persons, it is said, can be found in the province who are unable to read. The qualifications for entering into the priestly order are good conduct and a fair measure of learning—such conduct at least as is good according to Buddhist tenets, and such learning as is esteemed among their votaries.

ARAL, a vast lake or inland sea, in the west of Asia, situated between lat. 43° 42′ and 46° 44′ N., and long. 58° 18′ and 61° 46′ E. It was known to the Persian geographers as the Sea of Khuwârizm or Khwarezm, from the neighbouring district of the Chorasmii, and derives its present name from the Kirghese designation of *Aral Denghis*, or Sea of Islands. Its length, from north to south, is 265 miles, and its breadth, from east to west, about 145. It is the greatest body of water in the steppes of Asia, next to the Caspian Sea, and is one of the largest lakes in the world. Its level is 117 (or, according to recent explorations, which, however, require verification, 250) feet above the Caspian, which is 84 feet below the Black Sea. It is bounded on the N. by the Ural steppes; on the W. by the rocky plateau of the Ust-Urt, which separates it from the Caspian; on the S. by the alluvial district of Khiva; and on the E. by the Kysyl-Kum, or Red Desert, and the Kara-Kum, or Black Desert. In the north the shore is comparatively low, and the coast-line is broken into a number of irregular bays, of which the most important are those of Sary-Chaganak and Paskevitch; and on the west an almost unbroken wall of rock extends from Chernycheff Bay southwards, rising towards the middle to a height of 500 feet. The southern coast is occupied by the delta of the Oxus (Jihûn, Amu-Daria, El-Jiryan), which divides into a number of channels, the most important of which, beginning from the west, are the Aibugir or Laudan, the Ulu- or Ulkun-Daria (Great River), and the Kuvan-Jarma, Kuk, or Yangy Su (New River), as it is variously called. The Laudan forms a vast swamp, 80 miles long, and about 20 broad, before it disembogues into the sea; and the whole of the neighbouring reaches are extremely shallow. The only other tributary of any size is the Jaxartes (Sîhûn, Syr-Daria, Shâsh), which enters towards the northern extremity of the east coast, and is suspected to be shifting its course and embouchure more and more to the north. The whole eastern coast is fringed with multitudes of small islands, and a number of considerable size are situated in the open towards the north and west. Kug-Aral, which is the largest of all, lies across the northern portion opposite the mouth of the Syr-Daria, and cuts off what is called the Kitchkine Dengis, or Little Sea. Proceeding south we find in succession, Barsa-Kilmas, Nicholas Island, Bellinghausen, Lasaroff, and, near the mouth of the Taldyk, Takmakdty. Upon some of these islands the Russian explorers found large numbers of antelopes, which showed by their perfect fearlessness, combined with their curiosity, that they had hitherto been undisturbed by man. For the most part the Sea of Aral is comparatively shallow, the depth towards the west coast being 37 fathoms, and towards the centre only 15. Navigation is rendered dangerous by the frequency and violence of the storms, and the almost total absence of shelter for ships. The north-east wind is the most prevalent, and sometimes blows for months together. The only other craft, except the steamships of the Russians, that venture on the waters, are the flat-bottomed boats of the Kirghese. The first vessel ever known to have been launched on the Aral was conveyed across the desert in pieces by the Russian Admiral Boutakoff, about 1848. The sea abounds with fish of various kinds, as the sturgeon, silurus, carp, and especially a species of herring; thus agreeing in its ichthyology with the Caspian, from which it is distant 150 miles. The water is only slightly brackish. During winter the northern portion is completely frozen, but towards the south it is very seldom that ice is formed to any extent. The Aral has no visible outlet; and to account for there being no increase in its size, it was supposed that there might be a subterraneous communication with the Caspian Sea or the Sea of Khuzar; but the evaporation is so great as not only to maintain an equilibrium, but even, it has been thought, to produce, as in the case of the Caspian, a gradual diminution. In regard to the period of the formation of the Aral there are two theories, each supported by high authority. According to Sir H. Rawlinson (*Proceedings of the Royal Geographical Society*, March 1867) the disturbances which produced the present lake took place in the course of the Middle Ages; while Sir Roderick Murchison contends (*Journal of Roy. Geog. Soc.* 1867, p. cxliv., &c.) that the Caspian and Aral have existed as separate seas before and during all the historic period, and that the main course of the rivers Jaxartes and Oxus was determined in a prehistoric period. The former bases his opinion largely on historical evidence; and the latter trusts principally to geological data. The whole subject has been recently reviewed in *Die Aralseefrage*, by Robert Roesler, Associate of the Imperial Academy of Sciences, Vienna, 1873.

ARAM, Eugene, was born of humble parents at Ramsgill in Yorkshire, in 1704. He received little education at school, but manifested an intense desire for learning. While still young, he married and settled as a schoolmaster at Netherdale, and during the years he spent there, he taught himself both Latin and Greek. In 1734 he removed to Knaresborough, where he remained as schoolmaster till 1745. In that year a man named Daniel Clark, an intimate friend of Aram, after obtaining a considerable quantity of goods from some of the tradesmen in the town, suddenly disappeared. Suspicions of being concerned in this swindling transaction fell upon Aram. His garden was searched, and some of the goods found there. As, however, there was not evidence sufficient to convict him of any crime, he was discharged, and soon after set out for London, leaving his wife behind. For several years he travelled through parts of England, acting as usher in a number of schools, and settled finally at Lynn, in Norfolk. During his travels he had amassed considerable materials for a work he had projected on etymology, to be entitled, a *Comparative Lexicon of the English, Latin, Greek, Hebrew, and Celtic Languages.* In February 1759 a skeleton was dug up at Knaresborough, and some suspicion arose that it might be Clark's. Aram's wife had more than once hinted that her husband and a man named Houseman knew the secret of Clark's disappearance. Houseman was at once arrested and confronted with the bones that had been found. He affirmed his innocence, and, taking up one of the bones, said "This is no more Dan Clark's bone than it is mine." His manner in saying this roused suspicion that he knew more of Clark's disappearance than he was willing to admit. He was again examined, and confessed that he had been present at the murder of Clark by Aram and another man, Terry, of whom nothing further is heard. He also gave information as to the place where the body had been buried in St Robert's Cave, a well-known spot near Knaresborough. A skeleton was dug up here, and Aram was immediately arrested, and sent to York for trial. Houseman was admitted as evidence against him. Aram conducted his own defence, and did not attempt to overthrow Houseman's evidence, although there were some discrepancies in that; but made a skilful attack on the fallibility of circumstantial evidence in general, and particularly of evidence drawn from the discovery of bones. He brought forward several instances where bones had been found in caves, and tried to show that the bones found in St Robert's Cave were probably those of some hermit who had taken up his abode there. He was found guilty, and condemned to be executed on the 6th August, three days after his trial. While in his cell he confessed his guilt, and threw some light on the motives for his crime, by asserting that he had discovered a criminal intimacy between Clark and his own wife. On the night before the 6th August he attempted to commit suicide by opening the veins in his arm; but he was discovered before life was extinct, and suffered the last penalty of the law. The story of Eugene Aram has been made the subject of a powerful ballad by Hood, *The Dream of Eugene Aram, the Murderer*, and of a romance by Bulwer Lytton, entitled *Eugene Aram.*

ARAMAIC LANGUAGES are so called from *Aram*, a geographical term, which in old Semitic usage designates nearly the same districts as the Greek word Syria. Aram, however, does not include Palestine, while it comprehends Mesopotamia (*Heb.* Aram of two rivers), a region which the Greeks frequently distinguish from Syria proper. Thus the Aramaic languages may be geographically defined as the Semitic dialects originally current in Mesopotamia and the regions extending S.W. from the Euphrates to Palestine. Philologically these dialects form a distinct group of Semitic languages (North Semitic), separated by grammatical and lexical peculiarities alike from the Middle Semitic (Hebrew, Phœnician) and from the South Semitic (Arabic, Ethiopic). Babylonia is not part of Aram, and the Semitic language of the Assyrian and Babylonian arrowhead inscriptions is not Aramaic.

All Aramaic dialects are characterised by poverty of vowels, by the disappearance of many of the forms of internal declension so characteristic of the original genius of Semitic speech, and by a tendency to analytical construction by the aid of relative particles in place of the earlier usage of the construct state. Along with these marks of degradation they retain some antique features lost in Hebrew and Arabic, and in particular, generally present the oldest consonantal forms, having mutes instead of sibilants and aspirates, in a way quite analogous to the relation of Low to High Dutch. A special Aramaic peculiarity is the enclitic use of the article as in modern Danish.

The tribes of ancient Aram never possessed political unity, their settlements being intersected by strips of desert with Arabian population. Thus, there must have been from an early time considerable diversity of dialect within the group, and apart from differences due to the very various ages of the extant literature, we are able to divide Aramaic into two main branches, commonly known as Chaldee and Syriac respectively, and distinguished partly by differences of pronunciation and vocabulary, but more conclusively by differences of grammatical flexion, especially in the verb. In comparison with the great age of this branch of Semitic, the whole Aramaic literature is of comparatively late date, and presents the languages in an advanced and in some sense exhausted stage of development.

The historical and geographical relations of Syriac and Chaldee respectively are involved in some obscurity. As the entire Chaldee literature is of Jewish origin, Hupfeld and others have attempted to refer the whole difference of this language from Syriac to an infusion of Hebrew elements. This view, however, is now generally given up, and it is agreed that Chaldee is no corrupt dialect, but a genuine Aramaic development. But where and when did the Jews give up their old language and adopt a foreign tongue? The explanation formerly adopted and embodied in the name Chaldee, which from the days of Jerome has been commonly used to designate the Jewish Aramaic, is that the change took place in Babylon. That the so-called Biblical Chaldee, in which considerable portions of the books of Ezra and Daniel are written, was really the language of Babylon, was supposed to be clear from Dan. ii. 3, where the Chaldeans are said to have spoken to the king in Aramaic, and accordingly the writer in the following verse passes from Hebrew to that language. But the cuneiform inscriptions show that the proper language of the Chaldeans was not Aramaic; and an examination of the very large part of the Hebrew Old Testament written later than the exile seems conclusively to prove that the substitution of Aramaic for Hebrew as the vernacular of Palestine took place very gradually. Under the Persian empire Aramaic was a sort of official language for the western provinces, and the Hebrews were in constant contact with Aramaic populations, so that the language of the many could not fail ultimately to supersede the language of the few. Hence most scholars are now agreed in holding that the term Chaldee is a misnomer, and that the dialect so called is really the language of the South-Western Arameans, who were the immediate neighbours of the Jews. Probably this doctrine would be no longer disputed but for the connection between the question before us and that of the date and authorship of Daniel In any case, the substitution of Aramaic for Hebrew as the vernacular of Palestine was completed before the time of Christ, and it is this dialect (not the language of the Old Testament Scriptures) which is designated in the New Testament as "Hebrew." The old Hebrew Scriptures were understood only by the aid of interpretations, which, at first oral, were set down in writing in the early centuries of our era, and form after the Biblical Chaldee the second main element of Chaldee literature, the so-called Targums. These versions or paraphrases arose partly in the Palestinian, partly in the Babylonian schools, and accordingly display considerable variety of dialect—the Palestinian Targums approaching most nearly to the Aramaic of Daniel and Ezra. But the Aramaic of the Targums is again very different from the language of every day life, as presented in the Talmuds of Babylon and Jerusalem. The Talmudic dialects show extreme phonetic and grammatical decay, but have hitherto been very inadequately investigated. The Aramaic of the Babylonian Talmud is more nearly allied to the Aramaic of the East than to the language of Palestine.

Of much greater historical importance than these Jewish dialects is the Aramaic of the north and east, which rose to a literary language under the name of Syriac, in the Chrstian schools of North Mesopotamia. Like so many other languages, the Syriac first received stable literary form by the translation of the Bible, the so-called Peshito. On this basis the language was assiduously cultivated for many centuries, especially in the renowned schools of Edessa and Nisibis, and possesses a very large literature, in which theology has a leading place, but which is also strong in other forms of composition, as history and poetry, and even extends into the domain of Occidental philosophy and science. The treatment of the latter subjects in a Semitic speech was rendered possible by the very great infusion of Greek elements (not merely technical terms, but even particles and the like) brought into the language by long centuries of Greek domination and culture. The period during which Syriac literature was most flourishing extends from the 4th to the 10th Christian century. From the later date onward, the language began to give way to Arabic, though some very distinguished authors, *e.g.*, Barhebræus, wrote as late as the 13th century. Even now the Syriac is used to some extent as the ecclesiastical language of various bodies of Christians, Jacobites, Nestorians, and Maronites. The systematic study of Syriac by grammars and lexicons was commenced pretty early. Of native grammarians, may be mentioned Jacob of Edessa (7th century) and Barhebræus; of lexicographers, Bar-Ali and Bar-Bahlul (9th and 10th centuries respectively). By the Maronites the study of Syriac was transplanted to Europe in the 16th century. A corrupt dialect (Neo-Syriac) is still spoken in some districts near Mosul, in Antilibanus, &c., and has been grammatically handled by Stoddart, Nöldeke, and others. Besides the two main branches of Aramaic already discussed, several minor Aramaic dialects claim to be noticed. The Samaritan dialect, spoken by the mixed population introduced into Northern Palestine after the deportation of the Ephraimites, has long been superseded as a living tongue by Arabic, but is still the sacred language of the Samaritan communities. The most important literary monument of this dialect is the Samaritan translation of the Pentateuch; but we possess also Samaritan liturgies and other remains. Another written dialect is the Mandean, the language of a mystical sect on the Euphrates and Tigris, whose *Book of Adam* has been edited by Norberg. Other dialects are known only from inscriptions, as the dialect of the Hauran, and that of certain Egyptian monuments.

Helps to the Study of the Aramaic Dialects.—There is as yet no good Grammar of the Chaldee dialects. That most commonly used is Winer's *Grammatik des biblischen und targumischen Chaldaismus*, which has passed through several editions, and of which there is an American translation by Riggs. Luzzato's *Elementi grammaticali del Caldeo Biblico e del dialetto Talmudico Babilonese* (Padua, 1865) is in some respects preferable to Winer. The *Chaldäische Grammatik* of Fuerst (Leipsic, 1835) is unfinished. The best Chaldee Lexicon is still the old *Lexicon Chaldaicum Talmudicum et Rabbinicum* of Buxtorf (Basil, 1640). The worthless modern reprint by Fischer is to be avoided, but the *Chaldäisches Wörterbuch* of J. Levy, 2 vols. Leipsic, 1867–68, may be used with caution. On the controversy as to the real character of the Chaldee dialects, the student may be referred to the books of introduction to the Old Testament, especially to Schrader's edition of De Wette, which gives full references to relevant literature. Of recent Syriac Grammars may be mentioned those of Hoffmann (*Grammaticæ Syriacæ Libri III.*, Halæ, 1827) and Uhlemann (*Grammatik der Syrischen Sprache*, 2 Aufl., Berlin, 1857) in Germany, and of Cowper (London, 1858) in English. An elaborate and pretentious reconstruction of Hoffmann's Grammar by Professor Merx of Tübingen, treats all the Aramaic dialects, but is not yet finished (part i. 1867, part ii. 1870). The Grammar of Amira (Rome, 1596) is still referred to. There is no complete Syriac Lexicon adequate to modern requirements. Michaelis's edition of Castellus (Göttingen, 1788), and Schaaf's *Lexicon Concordantiale* to the New Testament (Leyden, 1708), are valuable; and a great Thesaurus, compiled from numerous sources, and from the collections of several scholars, is now being published by the Clarendon Press under the editorship of Dr Payne Smith. On the Samaritan literature see the introduction to Nutt's *Fragments of a Samaritan Targum*, London, 1874. There is a Samaritan Grammar by Uhlemann (Leipsic, 1837), and an Essay on the Mandean dialect by Nöldeke (Gottingen, 1862). The Aramaic inscriptions have been investigated by Gesenius, De Vogüé, Noldeke, and others. (W. R. S.)

ARAN ISLANDS, South, three islands of carboniferous limestone, which lie across Galway Bay, on the west coast of Ireland, in a south-easterly direction, forming a kind of natural breakwater. They are called respectively—beginning with the most northern—Inishmore (or Aranmore), the Great Island; Inishmaan, the Middle Island; and Inisheer, the Eastern Island. The first has an elevation of 354 feet, the second of 259, and the third of 202. These islands are remarkable for a number of architectural remains of a very early date. In Aranmore—which has been sung by Moore—there stand, on a cliff 220 feet high, large remains of a circular cyclopean tower, called Dun-Aengus, ascribed to the Fir-bolg or Belgæ; and seven other similar structures are found in the group. Aranmore also bears the name of *Aran-na-naomh*, Aran-of-The-Saints, from the number of religious recluses who took up their abode in it, and gave a celebrity to the holy wells, altars, and shrines, to which many are still attracted. No less, indeed, than twenty buildings of ecclesiastical or monastic character have been enumerated in the three islands. The total area is 11,287 acres.

ARANDA, Pedro Pablo Abarca y Bolea, Count of, a descendant of a noble family in Aragon, was born at Saragossa, 21st Sept. 1718. He served for several years in the army, and, after retiring with the rank of lieutenant-colonel, spent some time in travelling through France, Italy, and Prussia. He seems to have fallen under the displeasure of Ferdinand VI., but on the accession of Charles III. in 1759, he was appointed ambassador to the court of Poland, an office which he held for several years. On his return he took the command of the army sent against the Portuguese, and gained some successes. He was then appointed captain-general of Valencia, from which place, two years later, in 1765, he was summoned to Madrid to assist in quelling an insurrection. His success was rewarded by the appointment to the Presidency of the Court of Castile. While holding this office he induced the king to give his consent to an order for the banishment from Spain of all the Jesuits. His further intention of abolishing the Inquisition was prematurely disclosed, and great indignation was excited against him. He was dismissed from the presidency of the council, and sent as ambassador to Paris. Here he was instrumental in bringing about peace between Spain and Britain. The presidency from which Aranda had been dismissed was held for a short time by his political adversary, Grimaldi, who was succeeded by the count of Florida Blanca. On the dismissal of the latter in 1792, Aranda was recalled to his former position, but from it he was again quickly driven by the influence of Godoy, the queen's favourite. Soon after he obtained permission to retire to his own estates, where he died in 1799.

ARANJUEZ (*Ara Jovis?*), a town in Spain, in the province of Madrid, situated 1640 feet above the sea, in a beautiful valley on the left bank of the Tagus, near its junction with the Jarama, 28 miles S.S.E. of the capital, and 22 E.N.E. of Toledo, and united by rail with both these cities. The master of the Order of Santiago had a country seat at Aranjuez in the 14th and 15th centuries, which passed, along with the mastership into the possession of the crown of Spain in the reign of Ferdinand and Isabella (1522). It became a favourite resort of the Spanish court during the spring months; and its successive occupants, from the Emperor Charles V. down to Ferdinand VII., modified it according to their respective tastes. The larger palace, a building in the French style, due to Philip V., stands at the meeting of the rivers, and is surrounded with the luxuriant foliage of oaks and sycamores and elms. Many of the elms, which were originally brought from England in the reign of Philip II., have attained an extraordinary size. The *Casa del Labrador*, or Farmer's House, as it is called, is a smaller palace built by Charles IV., and full of elaborate ornamentation. The inhabitants of the town continued to live for the most part in troglodytic fashion in excavations in the hill-sides, till the reign of Charles III. (1759–1788), whose minister, Grimaldi, laid the town out in imitation of the Dutch style, with straight wide streets, and uniform two story houses. It contains two parish churches—*S. Antonio* and *del Payés*—an hospital, a Franciscan convent, a bull-ring, and a theatre. The manufactures are flour, chocolate, leather, and glass; but most of the inhabitants are dependent on agricultural pursuits. A yearly fair is held on the 4th, 5th, and 6th of September. Great attention is given to the rearing of horses and mules, and the royal stud used to be remarkable for the beauty of its cream-coloured breed. The ordinary population is between 3000 and 4000, but during the residence of the court, the number of inhabitants used to rise to 20,000. The place suffered severely from the French during the Peninsular War. The treaty of 1772 between France and Spain was concluded at Aranjuez; and there the insurrection broke out in 1808, which ended in the abdication of Charles IV.

ARARAT. This name, originally designating a whole district of Asia (Gen. viii. 4), has long been appropriated by the uniform usage of Europeans to the lofty Armenian mountain which stands on the confines of the Russian, Turkish, and Persian dominions, in lat. 39° 42′ N., long. 44° 35′ E., known to the Armenians as *Masis*, to the Turks as *Ak-Dagh*, and to the Persians as *Kuh-i-Nuh*, or Noah's Mountain. Whether the tradition, which makes it the resting-place of the ark, is of any historical value or not, there is at least poetical fitness in the hypothesis, inasmuch as this mountain is about equally distant from the Black Sea and the Caspian, from the Mediterranean and the Persian Gulf. Another tradition—accepted alike by Christians and Mahometans—fixed on Mount Judi, in the south of Armenia, as the ark's resting-place. There so-called genuine relics of the ark were exhibited, and a monastery and mosque of commemoration were built; but the monastery was destroyed by lightning in 776 A.D., and the tradition has declined in credit. Mount Ararat is the culminating point of the Armenian plateau, which reaches at its base a height of 3000 feet. From this it rises in a graceful isolated cone (having at its side the more perfect but less lofty cone of Little Ararat) far into the region of perennial snow. It was long believed by the Armenian monks that no one was permitted to reach the "secret top" of Ararat with its sacred remains. The summit, however, has been frequently reached in the course of this century. Tournefort had failed in 1700; the Pasha of Bayazeed had been equally unsuccessful; but on Sept. 27, 1829, Dr Parrot of Dorpat, a German in the employment of Russia, set foot on the "dome of eternal ice." Ascents have since been made by Antonomoff (1834 and 1843); Wagner and Abich (1845); Chodzko, Chanykoff, Moritz, and a party of Cossacks in the service of the Russian Government (1850); Major Stuart (1856); and Colonel Monteith (1856). Mr Freshfield, who reached within about 800 feet of the summit in 1868, thus describes the mountain:—"It stands perfectly isolated from all the other ranges, with the still more perfect cone of Little Ararat (a typical volcano) at its side. Seen thus early in the season (May), with at least 9000 feet of snow on its slopes, from a distance and height well calculated to permit the eye to take in its true proportions, we agreed that no single mountain we know presented such a magnificent and impressive appearance as the Armenian Giant." It has been ascertained that the higher peak, or *Ak-Dagh*, is 17,112 (1331 higher than Mount Blanc), and the lower, or *Allah-Dagh*, about 13,085 feet above the level of the sea. That the mountain was of volcanic origin was well known, but all eruptive activity was supposed to have long ceased. Reineggs was discredited, it may be justly, when he spoke of seeing it in eruption in 1785. But in 1840 there was a vast eruption of sulphurous vapours from its sides, and a tremendous earthquake shook the surrounding country. The village of Arguri and the monastery of St James were destroyed, and great damage was done to Nakhchevan, Sharur, and Ardubad. Major Voskoboinikoff's Report (*Athenæum*, 1841, p. 157) was, as Wagner has pointed out, erroneous in some of its details, but in the main trustworthy. There are a number of glaciers in the upper portion, and the climate of the whole district is very severe. The greater part of the mountain is destitute of trees, but the lower Ararat is clothed with birches. The fauna and flora are both comparatively meagre.

(Parrot, *Reise zum Ararat*, Berlin, 1834; Wagner, *Reise nach dem Ararat, &c.*, Stuttgart, 1848; Abich, in *Bulletin de la Soc. de Geogr. de France*, 4 ser. part i., and in *Monatsberichten der Ges. für Erdk. zu Berlin*, 1846, and his *Die Besteigung des Ararat*, St Petersburg, 1849; Dubois, *Voy. autour du Caucase*; Morier's *Second Journey*; D. W. Freshfield, *Travels in the Central Caucasus and Bashan*, 1869.)

ARAS, the ancient *Araxes* (Turk. and Arab. *Ras*, Armen. *Erash*, Georg. *Rashki*), a river which rises south of Erzeroum, in the Bingöl-Dagh (Mountain of the Thousand Wells), and flows east through the province of Erzeroum and Russian Armenia, passing between Mount Ararat and Erivan, till it joins the Kur (*Cyrus*) coming from the north, and falls with it into the Caspian Sea. Its separate course is about 500 miles long, and it receives a number of tributaries, of which one of the chief is the Zenghi, which passes by Erivan and drains lake Goukcha or Sivan. A number of towns are situated on the banks of the Aras, as Hassan-Kaleh, Kagisman, and Abbasabad. It forms the boundary between Russia and Persia from 44° to 48° E. long. The Araxes was known by hearsay to Herodotus, and is the Phasis of Xenophon. It is a rapid and muddy stream, dangerous to cross when swollen by the melting of the snows in Armenia, but fordable in its ordinary state.

ARATUS, one of the rulers of Sicyon, was born in that city, 271 B.C. His father, Clinias, was slain by Abantidas; and Aratus, then seven years of age, only escaped a similar fate through the kindness of Soso, the sister of Abantidas, who had him conveyed secretly to Argos. At the age of twenty he regained without bloodshed his native city of Sicyon, and induced the citizens to join the Achæan League. He obtained assistance in money from Ptolemy, whom he visited, and soon after (245 B.C.) he was elected general of the League. Two years later, when again general, he took Corinth from the Macedonians, and united it to the League. About the same time he defeated the Ætolians at Pellene, and his success drew many other cities into the League, which, under the careful management of Aratus, was rapidly becoming a powerful confederation. Its power, however, roused the jealousy of Cleomenes of Sparta, and in 226 war broke out between the Spartans and Achæans. Cleomenes was victorious at Lycæum, Megalopolis, Hecatombæum, and Dyme, and completely broke the power of the League. As a last resource, Aratus entered into negotiation with Antigonus of Macedonia, and, by promising to deliver up Corinth, secured his assistance. Antigonus was made general of the League, and in 222 totally defeated Cleomenes in the battle of Sellasia. The general peace which now ensued was broken by the turbulent Ætolians, who invaded Achæa. Aratus having marched against them, suffered so severe a defeat at Caphæ that he was accused and tried for mismanagement; his former great services alone saved him from suffering the penalty of failure. Philip of Macedonia, who was then called in to the assistance of the Achæans, succeeded in establishing peace, but his ambition was roused by the hope of obtaining supremacy in Greece. The counsels of Aratus became distasteful to him, and Plutarch does not hesitate to ascribe the death of Aratus, a few years later (213 B.C.), to poison administered by the command of his royal master. The body was conveyed to Sicyon, where a monument was erected as a memorial of his services. Aratus is one of the few great names in later Greek history. He had an intense hatred of tyrants, and devoted his whole life to the attainment of liberty for Greece. His talents as a statesman were great, but their effect was marred by his incompetence and want of success as a general.

ARATUS, a Greek poet, was born at Soli, in Cilicia. The date of his birth is uncertain, but it is known he lived about 270 B.C., and as he was court-physician to Antigonus Gonatas, king of Macedonia, he must have been contemporary with several of the great Alexandrian writers,—

Aristophanes of Byzantium, Aristarchus, and Theocritus. Though not an Alexandrian, Aratus has all the characteristics of that school of poetry. He was learned, and verse furnished him with a vehicle for conveying scientific instruction. His only extant works are two poems, or two fragments of one poem, the first, called Φαινόμενα, in 732 lines, the second, Διοσημεῖα, in 422 lines. The *Phænomena* is a versified imitation or modification of a prose work on astronomy by Eudoxus. It contains little of any value, but one verse has become famous through being quoted by St Paul in his speech from Mars Hill (Acts xvii. 28). The Diosemeia or Prognostics is a treatise on the signs of the weather, accompanied with practical rules. It is imitated to some extent by Virgil in his *Georgics*. The poems of Aratus were very popular, particularly among the Romans, who produced three translations, one by Cicero, another by Cæsar Germanicus, the third by Festus Avienus. The best modern editions of Aratus are those of Buhle, Buttmann, and Bekker.

ARAUCANIA, a territory of South America, between lat. 37° and 39° 50′ S., and long. 70° and 75° 20 W. It is bounded on the N. by the river Biobio, which separates it from Chili, S. by the Valdivia, E. by the Andes, and W by the Pacific Ocean. See AMERICA, vol. i. p. 701, and PATAGONIA.

ARAUCARIA, a genus of Coniferous trees included under the tribe Abietineæ, and the sub-tribe Araucariæ. The sub-tribe has been thus defined:—Leaves flat, often four-angled, arranged more or less in a spiral manner; male flowers in cylindrical terminal spikes, anthers six or more in two rows; female flowers in cones, which are large and globose; scales of the cone linear, arranged in a spiral manner, deciduous (falling off); seeds solitary, pendulous, usually without wings; cotyledons two, entire or divided into two. The species of the genus are magnificent evergreen trees with whorled branches, and stiff, flattened, pointed leaves, found in Brazil and Chili, Polynesia and Australia. The name of the genus is derived from Araucania, the district of South America where the trees grow. *Araucaria imbricata*, the imbricate-leaved pine, or the Chili pine, was introduced into Britain in 1796. It is largely cultivated, and usually stands the winter of Britain; but in some years, when the temperature fell very low, the trees have suffered much. On Christmas 1860, the temperature in the Edinburgh Botanic Garden fell to −8° Fahr., and some fine Araucarias, 24 and 25 feet high, were killed. Care should be taken in planting these trees to select a spot somewhat elevated and well drained. The tree grows to the height of 150 feet in the Cordilleras of Chili. The cones borne by the trees are from 8 to 8½ inches broad, and 7 to 7½ inches long. The wood of the tree is hard and durable. This is the only species which can be cultivated in the open air in Britain. *Araucaria brasiliana* (A. Rich.), the Brazil pine, is another species of the genus. It is a native of Brazil, and was introduced into Britain in 1819. It is not so hardy as *A. imbricata*, and requires protection during winter. It is grown in conservatories for half-hardy plants. *Araucaria excelsa* (R. Br.), the Norfolk Island pine, receives also the names of *Altingia excelsa*, *Eutassa* and *Eutacta excelsa*. It is a native of Norfolk Island and New Caledonia. It was introduced into Britain in 1793. It cannot be grown in the open air in Great Britain, as it requires protection from frost. It is more tender than the Brazilian pine. It is a majestic tree, sometimes attaining a height of more than 220 feet. The scales of its cones are winged, and have a hook at the apex. *Araucaria Cunninghami*, called also *Eutacta Cunninghami*, the Moreton Bay pine, is a tall tree found on the shores of Moreton Bay, Australia. It requires protection in this country during the winter. *Araucaria Bidwilli* (Hook.), the Bunya-Bunya pine, found on the mountains of Eastern Australia, between the rivers Brisbane and Burnett, at 27° S. lat., is a noble tree, attaining a height of 100 to 150 feet, with a straight trunk and white wood. It bears cones as large as a man's head. Its seeds are very large, and are used as food by the natives. *Araucaria Rulei* (Muell.) is another species. It is a tree of New Caledonia, which attains a height of 50 or 60 feet. *Araucaria Cookii* (R. Brown) is another coniferous tree of New Caledonia, attaining a height of 150 feet. It is found also in the Isle of Pines, and in the New Hebrides.

ARAVALLI HILLS, a range of mountains in India, running for 300 miles in a north-easterly direction through the Rajputáná states and the British districts of Mairwárá and Ajmír, situated between 24° and 27° 10′ N. lat., and between 72° and 75° E. long. They consist of a series of ridges and peaks, with a breadth varying from 6 to 60 miles, and an elevation of 1000 to 3000 feet, the highest point being Mount Abu, rising to 5655 feet, near the south-western extremity of the range. (See ABU.) The geology belongs to the primitive formation—granite, compact dark blue slate, gneiss, and sienite. Colonel Tod remarks the dazzling white effect of their peaks—an effect produced, not by snow, as among the Himálayas, but by enormous masses of vitreous rose-coloured quartz. On the north their drainage forms the Luní and Sakhí rivers, which fall into the Gulf of Cutch. To the south, their drainage supplies two distinct river systems, one of which debouches in comparatively small streams on the Gulf of Cambay, while the other unites to form the Chambal river, a great southern tributary of the Jamná, flowing thence, *viâ* the Ganges, into the Bay of Bengal on the other side of India. The Aravalli hills are for the most part bare of cultivation, and even of jungle. Many of them are mere heaps of sand and stone; others consist of huge masses of quartz heaped upon each other. The valleys between the ridges are generally sandy deserts, with an occasional oasis of cultivation. At long intervals, however, a fertile tract marks some great natural line of drainage, and among such valleys Ajmír city, with its lake, stands conspicuous. The hills are inhabited by a very sparse population of Mairs, an aboriginal race. For long these people formed a difficult problem to the British Government. Previous to our accession they had been accustomed to live, almost destitute of clothing, by the produce of their herds, by the chase, and by plunder. But Ajmír having been ceded to us in 1818, the Mair country was soon afterwards brought under British influence, and the predatory instincts of the people have at the same time been controlled and utilised by forming them into a Mairwárá battalion. As the peaceful results of British rule developed, and the old feuds between the Mairs and their Rájput neighbours died out, the Mair battalion was transformed into a police force. The Aravalli mountaineers strongly objected to this change, and pled a long period of loyal usefulness to the state. They have accordingly been again erected into a military battalion, and brought upon the roll of the British army. The Aravalli hills send off rocky ridges in a north-easterly direction through the states of Alwar and Jaipur, which from time to time reappear in the form of isolated hills and broken rocky elevations to near Dehli.

ARBACES, the founder of the Median empire in 876 B.C., was one of the generals of Sardanapalus, king of Assyria, and had command of the contingent from the province of Media. He conspired with Belesys, a Chaldean priest, who commanded the troops from Babylon, and having gained over several other officers of the king, they revolted. After a short contest Sardanapalus was defeated, and committed suicide. The dynasty founded by Arbaces lasted till its overthrow by Cyrus, 559 B.C. This account of the Median empire rests on the authority of Ctesias, as given in Diodorus (ii. 24, 34), and cannot be reconciled with what is stated by Herodotus, who is probably referring to another event. Arbaces, the Mede, is to be distinguished from the satrap of the same name who commanded a division of the army of Artaxerxes in his war with his brother Cyrus.

ARBELA (τὰ Ἄρβηλα), now Arbîl or Erbîl, a small town in the province of Shehrezur, situated to the west of the Tigris, in the plain between the Greater Zab (*Lycus*) and the Lesser Zab (*Caprus*), and on the route between Mosul (*Nineveh*) and Baghdad, about 40 miles from the former. The greater part of the town, which seems at one time to have been very large, is built on an artificial hill about 150 feet high. Arbela has given its name to a battle fought (331 B.C.) between Alexander the Great and Darius Codomannus,—though, in fact, the scene of the conflict was Gangumela, and it was only in the subsequent pursuit that the conquerer arrived at Arbela, where Darius had left his baggage and treasure. It became the seat of the Eyubide Sultan Saladdin, in 1184, was bequeathed in 1233 to the caliphs of Baghdad, was plundered by the Mongols in 1236 and in 1393 by Timour, and was taken in 1732 by the Persians under Nadir Shah. The population, which varies from 2000 to 6000, is chiefly composed of Koords.

ARBITRAGE (from the French *arbitrer*, in the secondary sense of comparing and settling accounts, derived in its turn from the primary sense of arbitrating disputes), is a term that is applied both to a calculation and to a trade: 1st, To the calculation of the relative simultaneous values at any particular moment of any particular merchandise, on *one* market, in terms of the quotations on one or more *other* markets, taking, of course, the exchanges into account; and 2d, To the business founded on such calculations, of buying (or *vice versâ*) wholesale in the cheapest market for the time being, and simultaneously reselling (or *vice versâ*) equal amounts in the dearest market, or if not simultaneously, at least as nearly simultaneously as post and telegraph will permit. Arbitrage proper is a separate, distinct, and well-defined business, with three main branches. Two of these, viz., arbitrage or arbitration in bullion and coins, and arbitration in bills, also called the arbitration of exchanges, fall within the businesses of bullion dealing and banking respectively. The third, arbitrage in stocks and shares, is arbitrage properly so called, and so understood, whenever the word is mentioned without qualification among business men, and it is strictly a Stock Exchange business. A few of the great financial firms outside the Stock Exchange combine the three arbitrations; they are dealers in bullion, in bills, and in stocks and shares all over the world; but, as a rule, the arbitrage properly known as such, is the business of an arbitrageur, who is almost always a member of a Stock Exchange or "Bourse," and his arbitrations with very few exceptions are neither in bullion nor in bills, but in Government and other stocks and shares. In this strict and accurate sense, arbitrage may be defined to be a traffic, consisting in the purchase (or sale) on one Stock Exchange, and simultaneous or nearly simultaneous, re-sale (or re-purchase) on another Stock Exchange, of the same amount in the same stocks or shares, which at any moment are found, on telegraphic or other advices, to be quoted and negotiable on two or more markets at a difference in price (arising from whatever temporary cause), sufficient to cover the cost of transmission, commission, interest, insurance, and leave an adequate profit over and above to be divided by the operators at both ends. The benefit to the various communities at large resulting from the operations of the arbitrageur consists—first, in the general and constant process of equalisation, equilibration, and the consequent stability in the prices of a large number of stocks and shares, and of an enormous amount of capital throughout the world; and second, in the greater inducement thus afforded for the economy of idle capital, by means of temporary investment in interest-bearing securities with a minimised risk of fluctuation. The great Government loans are, in the first instance, the natural subject-matter of arbitrage; and then, in a minor degree, a variety of other securities. British Consols, however, form one great exception to the rule, inasmuch as, from one cause or another (but mainly because they are almost entirely held in *one* country), no arbitrage business is done in these Consols, notwithstanding that they can be now dealt in "To Bearer." On the other hand, there is an enormous arbitrage business in the new French Five per cents., which, with the United States "Five-Twenties," covering between them a round *five hundred millions sterling*, probably stand first in the present list of arbitrage stocks. Indeed, but for the system of arbitrage, it is not easy to see how the great French loans of 1871-72 could have been carried at all without convulsing the financial world. Arbitrage, however, by making the new security universally negotiable, enabled all the great bankers and capitalists of the world—European, American, and East Indian—to join hands simultaneously in concluding an operation gigantic even for modern times. Next to "French Fives" and "U. S. Five-Twenties," on the arbitrageur's list would come, in various order, according to the men and the circumstances, "Turkish," "Egyptian," "Italian," "Spanish" "Russian," some South American stocks, and to a very considerable extent, the shares and obligations of the great Lombardo-Venetian Railways. And these stocks, if we add some East Indian securities, cover perhaps the widest area of international arbitrage. But a vast variety of minor securities constitute financial *flora*, so to speak, with minor and local areas of distribution, known only to particular localities, or to financial specialists. It has been stated above that some great financial houses do each kind of arbitration themselves. Similarly, one or two great firms of arbitrageurs do their own bill broking; but although arbitrage business is carried on by a considerable number of the leading Stock Exchange firms, there are perhaps only two that arbitrate their own bills—this arising from certain regulations that were passed by the London Stock Exchange in 1829 not having a retrospective effect. With these exceptions, the arbitrageurs do not undertake the banking part of the business themselves, but pay their bankers a margin to do it for them. The details of the system of arbitrage, and all the combinations with other business that may arise, constitute a special profession.

The literature of the subject is extremely meagre. Mr Goschen's *Theory of Foreign Exchanges*, London, 1866, is general and theoretical, but throws great light upon particular aspects of the philosophy of arbitrage, without touching specially on the details of the subject itself. The principal other works are—Kelly's *Cambist*, 1811, 1835; Otto Swoboda, *Die Kaufmannische Arbitrage*, Berlin, 1873, and *Börse und Actien*, Cologne, 1869; Coquelin et Guillaumin, *Dictionnaire de l'Economie politique*, Paris, 1851-53; Ottomar Haupt, *London Arbitrageur*, London, 1870; Charles le Touzé, *Traité Théorique et Pratique du Change*, Paris, 1868; Tate, *Modern Cambist*, London, 1868; Simon Spitzer, *Ueber Münz- und Arbitragenrechnung*, Vienna, 1872; J. W. Gilbart, *Principles and Practice of Banking*, London, 1871.

ARBITRATION, a term derived from the nomenclature of the Roman law, and applied to an arrangement for taking, and abiding by, the judgment of a selected person in some disputed matter, instead of carrying it to the established courts of justice. Arrangements for avoiding the delay and expense of litigation, and referring a dispute to friends or neutral persons, are a natural practice, of which traces may be found in any state of society; but it is to the Justinian jurisprudence that we owe it as a system which has found its way into the practice of European nations in general, and has even evaded the dislike of the English common lawyers to the civil law. The eighth section of the fourth book of the Pandects is devoted to this subject. Almost all the advantages, as well as the defects of the system in modern practice, seem to have been anticipated by the Roman jurists. Some of the civilians make a distinction between the *arbitrator*, the name applicable to a person voluntarily chosen by parties to decide disputes, and the *arbiter*, an officer to whom the prætor is supposed to have remitted questions of fact as to a jury. In this sense arbiters appear to have been employed as a substitute for jury trial in some of the old provincial laws of France; and hence, perhaps, it comes that, by a very remarkable provision in the French code of commerce, all questions between partners touching the partnership must be referred to arbitration. In the code of civil procedure the title *des arbitrages* is treated so fully and minutely, as very forcibly to convey the impression of a separate system of voluntary jurisdiction, being created for performing what ought to be accomplished by the ordinary tribunals in a well-regulated judicial system. In Scotland the practice of arbitration has been imported from the Roman law without requiring, as in England, statutory intervention. It is one of the advantages of the Scottish system of registration that the decree-arbitral, or decision of the arbiter, when recorded in pursuance of the consent of the parties in their contract of arbitration or submission, can be enforced as the decree of a court.

Arbitration in Scotch Law.—This term is applied to the contract whereby a dispute is referred to one or more persons by the parties interested, and so withdrawn from the cognisance of the ordinary tribunals. When one person only is chosen he is called sole arbiter or arbitrator; when more than one, an umpire or oversman is appointed either in the contract or by the arbiters themselves, and his award is final if the arbiters differ in opinion. The contract is properly entered into by deed, duly attested and stamped, and is termed a *submission*. Submissions are either general or special; the former including all disputes subsisting at the time, the latter restricted to certain specified matters. The judgment when promulgated is termed the award or decree-arbitral. The deed of submission contains a clause authorising registration for execution, under which, on registration in the books of a competent court, witnesses may be cited and the decree-arbitral put to execution. The procedure may be by written pleadings, and a formal record may be made up if the arbiters deem that desirable. If the determination of the matter falls on the oversman, he may order further debate before deciding. Unless the submission provides otherwise, the powers of the arbiters fall on the expiry of one year; but if it contain a power of prorogation, the arbiters may prorogate from year to year; and in all cases the parties themselves may renew the reference after it has fallen. By Act of Regulations, 1695, c. 25, decrees-arbitral are declared not to be reducible except on the grounds of bribery, corruption, or falsehood; this has, moreover, been so interpreted as not to exclude reduction when the arbiters have plainly travelled out of the powers conferred on them by the submission, or where their procedure has been grossly irregular, *e.g.*, taking evidence in absence of one of the parties. An arbiter has the power of awarding costs, even though the deed contain no such provision. It is the general rule that a reference is ineffectual where the arbiters are not named, or where an arbiter is merely designated as the holder of an office, *e.g.*, the Lord Advocate. To this there is, however, an exception, where in a contract the parties bind themselves to refer, and where a reference is necessary to work out the contract. A rule in friendly societies to refer disputes is binding. Arbiters having once accepted, cannot renounce their office at pleasure; and if they do so, become liable in damages.

Judicial References have been long known to the law of Scotland. When an action is in court the parties may at any stage withdraw it from judicial determination, and refer it to arbitration. This is done by minute of reference to which the court interpones its authority. When the award is issued it becomes the judgment of the court. The court has no power to compel parties to enter into a reference of this kind, and it is doubtful whether counsel can bind their clients in such a matter. A judicial reference falls like the other by the elapse of a year; and the court cannot review the award on the ground of miscarriage. By 13 and 14 Vict. c. 36, § 50, a provision is introduced whereby parties to an action in the Supreme Court may refer judicially any issue for trial to one, three, five, or seven persons, who shall sit as a jury, and decide by a majority. The Consolidation Acts in reference to the acquisition of lands, &c., for public undertakings, such as railways, also contain provisions for settlement of disputes by arbitration.

Arbitration, in the Law of England, is described by Blackstone as an arrangement by which "the parties injuring and injured submit all matters in dispute concerning any personal chattels or personal wrong to the judgment of two or more *arbitrators*, who are to decide the controversy; and if they do not agree, it is usual to add that another person be called in as *umpire*, to whose sole judgment it is then referred; or frequently there is only one arbitrator originally appointed." Proceedings in arbitration were regulated by the Act 9 and 10 Will. III. c. 15, which allowed the submission to be made a rule of any of the courts of record and subsequent statutes. It may be said in general that all questions relating to civil rights may be referred to arbitration, *e.g.*, personal damages, disputes about real property, and pure questions of law. How far questions involving matters of criminal law may be made the subject of arbitration is not quite clear. In many cases the aggrieved person, having a remedy by indictment as well as by action, may compromise the criminal process by referring his civil rights to an arbitrator; but the more serious criminal offences of course could not be dealt with in this way. An arbitrator ought to have no personal interest in the subject of dispute, but this is almost the only restriction recognised by the law. Idiots, lunatics, infants, and married women, who are under a general rule of disqualification in law, may all be arbitrators, for it is said, the parties have selected their own judges and must abide by their choice. In certain cases of arbitration under a statute, the arbitrator must be taken from some special class, *e.g.*, in settling disputes about the proportional expense of county prisoners in a borough gaol, the arbitrator must be a barrister. Under the Common Law Procedure Act of 1854, the reference is to the master of the court. The submission to arbitration may be by agreement between the parties, by order of a court or judge, or by compulsion under the Common Law Act, 1854, or under special statutes. A verbal submission, besides other obvious disadvantages, cannot be made a rule of court. The statute 9 and 10 Will. III. provided that persons might agree that their submission should be made a rule of court, but the insertion of the consent clause in the submission was necessary. The Common Law Procedure Act, 1854, § 17, provides that every agreement or submission to arbitration by consent, whether by deed or instrument in writing, not under seal, may be made a rule of any one of the superior courts of equity or law at Westminster, on the application of any party thereto, unless such agreement or submission contain words purporting that the parties intend that it should not be made a rule of court; or if any particular court is specified, the submission shall be made a rule of that court only. The court has no jurisdiction until the submission has been actually made a rule of court, and that is seldom done until it is necessary to enforce or set aside the award. The courts are very jealous of any attempt to "oust their jurisdiction," by agreements to refer differences not yet risen, or covenants not to sue in respect of such differences. The 11th section of the Common Law Procedure Act, however, enables a defendant to take advantage of an agreement to refer by applying to the court to stay proceedings in the actions, and compel the plaintiff to resort to arbitration. In a pending action the matters in dispute may by consent of the parties be referred to arbitration, before or after the action is called on trial, by a rule of court, or by order of a judge at the trial. If it should be made to appear, at any time after the issuing of the writ, to the satisfaction of a court or the judge that the "matter in dispute consists wholly or in part of matters of mere account," the court or judge may order such matter to be referred to an arbitrator or an officer of the court (Common Law Procedure Act, § 3). At the trial of any issue of fact, matter of account therein arising may by order of the judge be similarly referred (section 6). In the latter case the power cannot be exercised after the jury is sworn. Among the statutes authorising reference to arbitration in cases of dispute the most important are the Land Clauses Consolidation Act, 1845, the Railway Clauses Act, 1845, and the Companies' Clauses Act, 1845—statutes which consolidate the "common clauses" usually inserted in Acts relating to the subjects named in their respective titles.

The powers of the arbitrator are very various. He may have the power of a jury or a judge at Nisi Prius, of a court in banco, of the Lord Chancellor, or of a master. The time for making the award is usually fixed by the submission; in other cases the legal period is three months. The time, however, may be enlarged by a rule of court, or by order of the arbitrators themselves. The award or decision of the arbitrators ought to decide finally all the questions in dispute, and ought to be certain and definite; it ought to be "mutual," *i.e.*, it should ascertain the rights and duties of both parties, and it must be possible and consistent with itself. It is a general rule that an award cannot be impeached for a mistake in law or in fact, although it is to be regretted that the practice of the courts on this point is by no means uniform. Where a demurrer, *i.e.*, an issue in point of law, was referred to arbitration, it was held that a mistake in law was no ground for setting aside the award. On the other hand, it has been held that a clear gross mistake affecting the whole award may be a good ground for having it set aside.

Arbitration, in International Law, is one of the recognised modes of terminating disputes between independent nations. Vattel calls it "a reasonable and natural mode of deciding such disputes as do not directly interest the safety of a nation." Heffter mentions six cases in which the judgment of the arbitrators would not be binding on the contending parties, viz., when the agreement has been insufficient, when the arbitrators have been incapable, when they have acted on bad faith, when the parties have not been understood, when the award is in excess of the reference, and when it is contrary to natural justice. Arbitration is sometimes spoken of as a universal substitute for war, but hitherto there has been no inclination, on the part of independent states, to submit any but secondary questions to the decision of neutral parties. The king of Prussia acted as arbitrator between England and France in 1843, in what were known as the Portendic claims. In the case of the "General Armstrong" privateer, between the United States and Portugal, the president of the French Republic (afterwards the Emperor Napoleon) acted as arbitrator. The most formal experiment in arbitration, however, was the Geneva Convention in 1872. The United States having for many years urged upon England the settlement of what were called the "Alabama" claims, a treaty was concluded by which the case was referred to five arbitrators named by England, the States, the Swiss Republic, the king of Italy, and the emperor of Brazil, respectively. Three new rules were at the same time drawn up for the arbitrators to follow in deciding on the liability of England. The award was in favour of America, and the English representative (Lord Chief-Justice Cockburn) was the only dissentient.

Arbitration is frequently employed to settle differences not of a legal character, *e.g.*, disputes between masters and workmen as to the rate of wages, hours of labour, &c.

ARBOGA, an ancient town in Sweden, in the government of Westerås, 30 miles S.W. of Westerås, on a river of the same name as itself, near its junction with the canal which joins the Malar and Hielmar Lakes. It was formerly a place of great trade, and contained five churches, three monasteries, and four chapels; but, though there is still some traffic in woollen, iron, and wooden wares, its prosperity has greatly decreased. It is well known as the seat of several important assemblies; particularly the parliaments of 1434, 1440, and 1471; and that of 1561, when the estates accepted the "Arboga articles," by which Eric XIV. restrained the power of his brothers. The town gives its name to the coinage of 1625 and 1627, which consisted of *klippingar*, or square copper pieces, and *fyrkar*, or farthings. In the neighbourhood there are mineral springs. Population, 3269.

ARBOIS, a town in France, lat. 46° 54′ N., long. 5° 47′ E., in the department of Jura, and arrondissement of Poligny, situated in a deep valley, on the Cuisance, 940 feet above the level of the sea. It has long been famous for its wines, which as early as 1493 were exempted from taxation in Burgundy and the German empire by Maximilian I. The rest of its trade consists in brandy, oil, fruits and flowers, grain, cattle, saltpetre, leather, cheese, earthenware, and paper. It was the seat of a commandery of the knights of Malta, had two monasteries and three nunneries, and still possesses a college and the ruins of a castle. The church of St Just is famous for its magnificent carvings in wood. Population, from 6000 to 7000.

ARBOR VITÆ (*Tree of Life*), is a name applied to species of Thuja and Biota. The name was given by Clusius, and its origin is uncertain. The plants belong to the Coniferous order, and have been placed in the tribe Abietineæ and the sub-tribe Cupressineæ (Cypresses), in which the anthers are 3 to 5, rarely 2; scales of the cones 4 or more, usually placed opposite to each other in a decussate manner, persistent (not falling off), seeds having usually 2 to 3 wings; cotyledons 2. *Thuja* or *Thuya occidentalis* (L.), is the Western or American Arbor Vitæ. The name Thuja seems to be derived from the Greek word θύος, signifying sacrifice, probably because the resin procured from the plant was used as incense. The plant is the *Cupressus Arbor Vitæ* of old authors. It is a native of North America, and ranges from Canada to the mountains of Virginia and Carolina. It is a moderate sized tree, and was introduced into Britain in 1596. In its native country it attains a height of about 50 feet. The leaves are small and imbricate, and are borne on flattened branches, which are apt to be mistaken for the leaves. When bruised the leaves give out an aromatic odour. The resin obtained from the plant has been used as a remedy in rheumatic affections. The flowers appear early in spring, and the fruit is ripened about the end of September. In Britain the plant is a hardy evergreen, and can only be looked upon as a large shrub or low tree. It does not furnish timber of good size. It is often cut so as to form hedges in gardens. The wood has been used for posts. Another species of Arbor Vitæ is the *Thuja orientalis* (Linn.), *Biota orientalis* (Endlicher). The latter generic name is derived from the Greek adjective *βιωτός*, formed from *βίος*, life, probably in connection with the name "tree of life." This is the Eastern or Chinese Arbor Vitæ. It is a native of Japan and China. It was introduced into France in the reign of Francis I. It has roundish cones, with numerous scales and wingless seeds. The leaves, which have a pungent aromatic odour, are said to yield a yellow dye. There are numerous varieties of this plant in cultivation, one of the most remarkable of which is the *Cupressus pendula* of Thunberg. (J. H. B.)

ARBORICULTURE

ARBORICULTURE comprises all that relates to the culture of trees, and is one of the great divisions of agriculture; it is a branch of rural economy of much more recent date than either the culture of grain and herbage plants, or the breeding and rearing of cattle. The culture of those plants which supply the food of man or nourish the domestic animals must have exclusively occupied his attention for many ages; whilst the timber employed in houses, ships, and machines, or for fuel, was found in the native woods. Hence, though the culture of fruit-trees, and occasionally of ornamental trees and shrubs, was practised by the Egyptians, Greeks, and Romans, the cultivation of timber-trees on a large scale only took place in modern times. In the days of Charlemagne, the greater part of France and Germany was covered with immense forests; and one of the benefits conferred on France by that prince was the rooting up of portions of these forests throughout the country, and substituting orchards or vineyards. Artificial plantations appear to have been formed in Germany sooner than in any other country, apparently as early as the 15th century. In Britain planting was begun, though sparingly, a century later. After the extensive transfers of property on the seizure of the church lands by Henry VIII., much timber was sold by the new owners, and the quantity thus thrown into the market so lowered its price, as Hollingshed informs us, that the builders of cottages, who had formerly employed willow and other cheap and common woods, now built them of the best oak. The demand for timber constantly increased, and the need of an extended surface of arable land arising at the same time, the natural forests became greatly circumscribed, till at last timber began to be imported, and the proprietors of land to think, first of protecting their native woods, afterwards of enclosing waste ground, and allowing it to become covered with self-sown seedlings, and ultimately of sowing acorns and mast in such enclosures, or of filling them with young plants collected in the woods,—a practice which exists in Sussex and other parts of England even now. Planting, however, was not general in England till the beginning of the 17th century, when the introduction of trees was facilitated by the interchange of plants by means of Botanic Gardens, which, in that century, were first established in different countries. Evelyn's *Sylva*, the first edition of which appeared in 1664, rendered an extremely important service to Arboriculture; and there is no doubt that the ornamental plantations, in which England surpasses all other countries, are in some measure the result of his enthusiasm. In consequence of a scarcity of timber for naval purposes, and the increased expense during the war of obtaining supplies from other countries, planting received a great stimulus in Britain in the early part of this century. Since the peace of 1815 the rage for planting with a view to profit has subsided; but there is a growing taste for the introduction of trees and shrubs from foreign countries, and for their cultivation for ornament and use. The profusion of trees and shrubs planted around suburban villas and country mansions, as well as in town squares and public parks, shows how much arboriculture is an object of pleasure to the people. The progress of the Arboricultural Society of Scotland, founded in 1854, and now containing 600 members, is a further indication of the national taste. Again, it may be remarked, that while isolated trees and old hedgerows are disappearing before steam cultivation, the advantages of shelter from well-arranged plantations are more fully appreciated; and more attention is paid to the principles of forest conservancy both at home and abroad. In all thickly peopled countries the forests have long ceased to supply the necessities of the inhabitants by natural reproduction; and it has become needful to form plantations either by Government or by private enterprise, for the growth of timber, and in some cases for climatic amelioration. In British dependencies the Government of India have acted with greatest vigour, having formed a State Forest Department, one object of which is the culture of the most valuable timber trees, as the teak in Malabar, Central Provinces, and Burmah, the Deodar in the Himalayan valleys, and Babool (*Acacia arabica*), &c., which covers large tracts both in South and North India, for the supply of railway fuel. The successful growth of Australian acacias and gum trees on the Nilgiri hills, mahogany in Bengal, and the spread of the cinchona cultivation on various mountain ranges, testify to the energy and skill with which the culture of exotic trees is carried on in British India. Before giving a sketch of the present practice of arboriculture, it is necessary to premise that this article is confined to well-known and hardy British trees, to a few valuable foreign species, and to plantations made with a view to timber produce.

General View of the Trees cultivated in Britain.—Trees differ from one another in regard to magnitude; slowness or rapidity of growth; suitableness for particular soils, and for elevated exposed situations, or low and sheltered places; texture, colour, and durability of the timber; delicacy or hardiness; ease or difficulty of propagation and rearing; production of showy flowers or fruits; and in other respects. In regard to magnitude, those trees which, in Britain, and in the same parallels of north latitude attain the greatest height, are the spruce and silver fir, the larch, and Scotch pine; and these also are the trees which, in most parts of Britain, produce the greatest quantity of timber in their trunks relatively to that contained in their branches, and in the shortest time. Poplars, willows, and some species of elm, are rapid-growing trees; their timber is rarely contained in one straight trunk, as in the case of pines, a considerable portion being distributed among the branches. Hence, where the speedy production of timber is the main object, pines are the preferable trees for planting. Where landscape effect is more desired than the production of timber, some of the poplars and elms, the Huntingdon willow, in some situations the birch, and in others, such as on the sea-shore, the sycamore and tamarisk, are suitable trees. Where the object is to clothe a sterile surface of dry sand, the birch, Scotch, Austrian, and cluster pines are among the best trees we have; and if the situation be exposed to the sea-breeze, the common and the Norway maple may be substituted; in the warmer parts of the island, the evergreen oak (*Quercus Ilex*); and for the marshes of the warmer parts, *Taxodium distichum* or deciduous cypress. For moist soils which cannot be drained, the white, trembling, and Ontario poplars have the property of sending their roots along the surface of the ground. Some species of willow and some poplars will grow near water in situations where their roots can enter into it, but will not grow in undrained soil. All the known species of trees and shrubs may be successfully grown in almost any kind of soil not beyond average moisture, dryness, or tenacity. In some soils, however, they thrive better than in others, and the timber produced generally varies in quality according to the soil. Thus, a rich soil, while it contributes to the rapid growth of the coniferous tribe, renders their timber less durable; and the same law holds, more or less, with every other species of tree.

The influence of climate on trees is much greater than that of soil; for, whilst many trees grow on any soil, every tree may be said to have its particular climate; that is, a climate in which, the soil and other circumstances being suitable, it will produce the largest and most enduring timber. Hence, when we take the geographical range of any species, we find what may be called a central climate, where it attains its largest size; and as it recedes from this climate, by latitude or elevation, into one either colder or hotter, it gradually diminishes in size, till it at last appears in the form of a shrub. Thus the common oak, which in Britain attains its largest size in Sussex and Hampshire, dwindles into a shrub on the mountains of Scotland and in the north of Africa; its degeneracy being occasioned in the one case by extreme cold, and in the other by extreme heat. Even within Britain the absolute character of trees, relatively to climate, is obvious. The English or narrow-leaved elm, supposed to be a native of Asia Minor and of China, attains a large size near London, producing a great bulk of timber in a short period, and ripening its seeds; while in Scotland it is considered only an ornamental tree. The Lombardy poplar, which in the central counties of England attains 125 feet in height in fifty years, is seldom seen of timber size in Scotland. The sweet chestnut and walnut, cultivated both for fruit and timber in many parts of England, can rarely be grown with profit for either purpose north of Newcastle.

Climate may be considered in regard to the average yearly and monthly temperature, and the degree of atmospheric moisture. A high annual temperature is no proof that a climate is suitable for trees; but a high summer temperature is suitable for many kinds, though the winter temperature may be very low. Thus the oaks and other trees of North America, attaining there a prodigious size, survive a winter as cold as that of St Petersburg, where no native oaks are found; but North America enjoys a very high temperature during summer, which rapidly develops the foliage, and matures the young shoots, enabling them to withstand the most rigorous winter. The much larger rainfall of that portion of America, as compared with St Petersburg, has doubtless important bearings on the question. In England the average temperature of the year is as great as that of the oak countries of the United States; but summers in the former country are comparatively cold, moist, and more cloudy; and though its winters are much milder than those of the latter, the spongy, unripened, young shoots are always more or less injured by frost. Again, in a mild climate, the trees of those countries which have a severe winter come into leaf earlier in the spring than the indigenous trees, and frosts often occurring at that season, they are liable to injury.

Evergreen trees form an important division of the vegetable kingdom; and of these there are two classes, distinct relatively to climate and temperature. The first comprises the conifers, which endure a degree of cold as great as that in which any deciduous tree thrives; and the second, the broad-leaved evergreen trees, such as the holly, box, laurustinus, laurel, evergreen oak, cork-tree, and the evergreen magnolia, trees of comparatively mild climates, and always indigenous on islands or on continents at low elevations, and at no great distance from the sea: hence the large number of evergreen trees which grow well in Britain, compared with those which survive the winter in the same latitude on the Continent.

A small proportion only of the trees cultivated in Britain are indigenous. Some are natives of other parts of Europe, and about two-thirds of the whole are from North America. Of these North American trees there are scarcely any worth cultivating in Britain for their timber, the summer not being sufficiently hot and light to bring the timber to maturity. The most useful trees of Britain are those which are indigenous, such as the oak, ash, broad-leaved elm, Scotch pine, &c.; or those found in the same hemisphere and in the same parallels of latitude, such as the larch, spruce, silver fir, &c. Of all trees cultivated in Europe, the most valued for the strength and durability of its timber is the common oak; and next perhaps to it, the larch. The trunk of the oak, when freed from the soft or outer wood, and thoroughly seasoned by exposure to the air, will last an unknown period of time in buildings and machines. The common European oak is more durable as timber than any of the American oaks, even when grown in America, unless we except the live oak (*Quercus virens*); and no timber equals it for ship-building, except the teak of India. The most generally useful timber grown in Britain is the Scotch fir; but as this is imported from the north of Europe, and a substitute for it from North America, it is not planted in Britain so extensively as it otherwise would be. The timber of the larch is more durable than that of the Scotch fir; but being apt to warp, and not so easily worked, it is less convenient for house-carpentry and joinery. The timber of the common ash is valuable in the construction of agricultural instruments and machines, and it is one of the few woods which are almost as valuable when young as when mature. The wood of the broad-leaved elm is strong and durable, but that of the English and Dutch elms is less so. The wood of the poplar and of the willow, when exposed to constant atmospheric changes, speedily decays; but when thoroughly seasoned, and kept perfectly dry, it is very durable.

Trees suited for Particular Purposes.

1. Conifers or resinous trees; 2. Hard-wood trees; and 3. Soft-wood trees.

1. *Conifers.*

Coniferous trees are characterised by straight erect trunks, with branches in regular tiers, which do not acquire the size of timber. They never send up shoots from the stool when cut over at the ground. The leaves are generally linear or needle-shaped, without veins, and evergreen. The seeds are produced in cones, and the whole plant is more or less resinous. They belong to the Gymnosperms, a family of the Dicotyledons.

The Larch (*Larix europæa*, D.C.) produces the most valuable timber, which is of great durability. Young larches, 6 or 8 feet high, are useful for sheep stakes, rustic palings, or dead fences. Young trees from 10 to 15 feet in height are found to form excellent hop-poles.[1] The

[1] For the durability of the mature timber, both in civil and naval architecture, we may refer to the *Transactions of the Highland Society of Scotland*, vol. xi. p. 165, and Loudon's *Arboretum Britannicum*, vol. iv. p. 2357.

bark of the larch is of considerable value in tanning; and as the leaves are deciduous, grass grows better under its shade than under any other species of pine. The larch is readily increased by seeds, which ripen abundantly in Britain; it prospers best in cool argillaceous soil, moist rather than dry, and at a considerable elevation above the sea. In certain soils, it is subject to decay of the heart-wood; and of recent years disease has seriously affected many of the finest plantations in this country, especially those beyond the age of fifty years. The larch is indigenous in the alpine region of Central Europe, and is a striking example of the successful introduction of an exotic, having been completely naturalised in Scotland for more than a century. Other species of *Larix*, natives of Siberia and North America, are inferior as forest trees.

The Scotch Pine (*Pinus sylvestris*, L.) is, next to the larch, the most valuable coniferous tree grown in Britain. It furnishes the yellow deal of the Baltic and Norway, which is unequalled by any other pine in Europe or North America. The best grown in Britain is produced in the native Highland forests; but there is reason to believe that artificial plantations, in similar soils and situations, would produce timber of nearly equal value. This tree is readily increased from seeds, which, unfortunately, are produced in the greatest abundance on stunted or inferior trees. It is very desirable to select seeds from the best varieties, as is now systematically done by nurserymen. The Highland variety with horizontal branches is that of highest repute. The Scotch fir is a native of Europe and Asia, but not of America.

The Cluster Pine (*Pinus Pinaster*, Sol.) is not adapted for general culture in Britain, and therefore scarcely merits to be ranked among British timber-trees. In some parts of the east coast of England, however, plantations of this tree have been raised; and in deep sandy soil it produces a considerable bulk of timber in a short time, thriving better when exposed to the sea-breeze than any other pine. The wood is not so durable as that of the Scotch pine; but it may be employed in the joinery of ordinary apartments. In general, however, it is not sufficiently strong for the roofing, joists, and other carpentry of dwelling-houses. In France, and particularly in the neighbourhood of Bordeaux, it is extensively grown on the sandy wastes, for the production of resin, tar, and pitch, which are obtained by incisions made in the trunk, and by subjecting the wood to the action of fire. The seeds are ripened in England. The young plants require more care in transplanting than those of most other pines, being furnished with a stronger tap-root. The cluster pine is a native of the south of Europe and Algeria.

The Spruce Fir (*Abies excelsa*, D.C.) is, as a British timber-tree, next in value to the Scotch pine. The young plants and the spray are durable; and the trunk grows straighter, more erect and slender, than the larch. The trunk is seldom sawn into boards; the great value of the tree being for poles of every kind, from those fit for the hop up to masts for smaller ships. It is often used with the bark on, for poles or fence-wood. In most parts of Europe, the poles used in the scaffolding employed in erecting buildings are formed of this tree, the wood being light and elastic. The spruce fir ripens seeds abundantly in Britain, from which plants are as easily raised as the Scotch pine and the larch. It prefers a rather moist soil, and only attains a great height in sheltered situations; but it grows anywhere to a size fit for hop-poles or fencing in a short time. Like the Scotch pine, it is subject to few diseases. The spruce is a native of Germany, Sweden, Russia, and Norway, but not of Britain or of North America.

The Silver Fir (*Abies pectinata*, D.C.) the largest of the European conifers, in various soils and situations produces a great bulk of timber in a comparatively short period; the timber is considered less strong and durable than that of the spruce fir or the Scotch pine, but it does not warp, and is adapted for all kinds of carpentry. The timber is white, and when not exposed makes excellent flooring. The tree is of slow growth for the first ten or twelve years; nevertheless, even in the north of Scotland it attains the height of 100 feet in sixty or seventy years. It ripens seeds in Britain, but more sparingly than the spruce fir, and plants are easily raised. It is in general healthy, but its cultivation is more difficult than that of the spruce, as the shoots of young trees are liable to be killed by frost. This species is also very subject to the attacks of an insect, *Eriosoma*, which often causes the death of the tree. The silver fir is a native of Central Germany, and of the mountains of Italy and Spain. Nearly allied is the *Abies balsamea*, balm of Gilead fir, a native of North America, which produces the Canada balsam, but it cannot be recommended for cultivation, as it is short lived.

Many conifers might be mentioned which, though not producing timber in Britain, are worthy of cultivation. Of the American pines we have the *Pinus Strobus*, L., Weymouth pine, which furnishes the white wood of American commerce. Several Californian pines have been introduced; of these *Abies Douglasii* is the most promising. *Cupressus Lawsoniana* is a beautiful tree, and also *Sequoia gigantea*, the mammoth tree, a general favourite in pleasure grounds, but a considerable period must elapse before we can judge of their being adapted for general culture as timber trees in this country. Of Asiatic conifers, *Cedrus Deodara* and *Libani* are much grown for ornament. *Pinus excelsa*, which resembles the Weymouth pine, and *Abies Smithiana* and *Webbiana* grow fairly in many parts of Britain; the Smithian pine being apparently the best adapted to the climate.

The Yew Tree (*Taxus baccata*, L.) attains its full perfection in this its native country; but on account of its slow growth it cannot be recommended to the planter, whose main object is profit.

Broad-leaved Trees (*bois feuillus*) in contradistinction to needle-leaved, are classed, according to their timber, in two subdivisions, hard and soft wood trees. They are characterised by large trunks and widely spreading woody branches, and broad leaves with branching veins; they send up shoots from the stool when cut over by the ground; and they are deciduous. They belong to the Dicotyledons.

2. *Hard-wood Trees.*

The hard-wood Timber-trees of Great Britain are characterised by the comparative hardness and durability of their wood, and comprise the oak, ash, elm, beech, sweet chestnut, walnut, and *Robinia* or false acacia. The British oak includes two sub-species, the stalked fruited or most common oak, *Quercus pedunculata*, and the stalkless fruited or less common oak, *Quercus sessiliflora*. The latter grows more erect and more rapidly than the other, particularly if the soil be good. In England and the lowlands of Scotland, *Q. pedunculata* is the commoner of the two oaks; but in North Wales and the hill parts of northern England, *Q. sessiliflora* is more frequent. Intermediate forms between these two oaks are found in England and elsewhere, and the leading botanists of the day unite them under the old name of *Q. Robur*. The wood of the oak is the strongest and most durable of all British timber-trees; but on account of the slowness of its growth it is not always the most eligible for planting. Oak plantations are more valuable than others when in a young state, on account of their bark. From the demand for oak as ship-timber, the price of trees fit for that purpose is always considerable; but the largest trunks employed in naval architecture do not afford an adequate return for the number of years they have stood on the ground. Accordingly, we find that the Governments both of France and England grow this description of timber largely in national forests. The wood of the oak is applicable to a greater number of uses than that of most other trees. Houses, ships, furniture, and machines may be formed almost entirely of oak, and consequently there is a ready sale for this timber almost everywhere. Hence there is more inducement to plant it in Britain than any other hard-wood tree. It is easily raised from acorns, which ought to be collected from the most vigorous trees. The British oak is a native of most parts of Europe, but not of Asia, Africa, or America.

The Ash (*Fraxinus excelsior*, L.) is in Britain next in value to the oak as a timber-tree. It requires a good deep loam with gravelly subsoil, and a situation naturally sheltered, such as the steep banks of glens, rivers, or lakes; in cold and wet clay it does not succeed. As the value of the timber depends chiefly on its toughness and elasticity, it is best grown in masses where the soil is good; the trunk is thus drawn up free from large side-branches. The tree is a native of Central Europe, and is easily propagated from seeds. It throws up strong root shoots. The ash requires much light, but grows rapidly, and its terminal shoots pierce easily through thickets of beech, with which it is often associated. Unmixed ash plantations are seldom satisfactory, because the foliage does not sufficiently cover the ground; but when mixed with beech it grows well, and attains great height and girth. Coppice shoots yield excellent hop-poles, crates, hoops, whip-handles, &c. The timber is much used for agricultural implements, and by coach-builders and wheelwrights. The supply of this valuable timber is annually becoming more limited on account of the decreasing use of hedgerow trees.

Of the Elm there are two species, the common or narrow-leaved elm (*Ulmus campestris*, L.), and the Wych or broad-leaved elm (*Ulmus montana*, L.) There are many varieties, such as the Dutch elm and the smooth-leaved or Huntingdon elm, the latter much valued for its timber. The narrow-leaved elm is not very common in Scotland, but in the central districts of England it becomes a handsome tree; and the timber is used for important purposes in ship-building, as well as in the construction of machines and agricultural buildings. The Wych elm is a hardy tree, of rapid growth; but, unless planted in masses, it seldom produces a straight handsome trunk. It strikes from layers with great facility, and when a branch touches the ground it is sure to take root. Few trees are more difficult to uproot than *Ulmus montana*, and it is rare to see it thrown over by the wind. It has a wide-spreading head, often sloping to one side, and lashing its neighbours with such force that it is sometimes interdicted in mixed plantations. Its timber is more durable than that of the English elm, or of any of the hybrids. It is much used in agricultural carpentry, in rural machinery, and in household furniture. The Wych elm produces abundance of seeds, which, if sown as soon as they are gathered, often come up the same year; but the English elm and the hybrids produce seeds sparingly, and are usually propagated by layers or by grafting on the Wych elm. One remarkable difference between the English and Wych elms may be noticed, viz., that the latter never throws up suckers from its roots; and it is therefore peculiarly valuable as a stock for the English elm, and for those varieties which do throw up suckers. There are other species and varieties of European elms, and several kinds of American elms, but none are deserving of culture in Britain as timber-trees. The elm is subject to the ravages of several insects, especially *Scolytus destructor*.

The Beech (*Fagus sylvatica*, L.) is one of the largest British trees, particularly on chalky or sandy soils. It is a handsome tree in every stage of its growth, but is more injurious to plants under its drip than other trees, so that shade-bearing trees, as holly, yew, and thuja, suffer. Its leaves, however, enrich the soil. In England and America the beech has a remarkable power of holding the ground where the soil is congenial, and the deep shade prevents the growth of other trees. It is often and most usefully mixed with oak and Scotch fir. The timber is not remarkable either for strength or durability. It was formerly much used in mill-work and turnery; but its principal use at present is in the manufacture of chairs, bedsteads, and a variety of minor articles. It is a native of the south of England, and of various parts of the continent of Europe. There are some varieties, particularly the purple and weeping beech; and there are one or two species natives of North America, but none of them deserve notice as timber-trees. It is propagated by its mast, which is produced plentifully in fine seasons.

The Hornbeam (*Carpinus Betulus*, L.) is an indigenous, moderate-sized, slow-growing tree, bearing a general resemblance to the beech, though of less value. It coppices well, and along with beech is valued for making hedges, as these trees retain their leaves a great part of the winter. The hornbeam is propagated by its nuts, which are produced in abundance. The wood is used for tool-handles, cog-wheels, and screws. Selby (*British Forest Trees*) recommends the use of the hornbeam as a nurse-tree.

The Sweet Chestnut (*Castanea vulgaris*, Lam.) is a large, long-lived, deciduous tree, of rapid growth while young, and attaining a vast size in South Europe (*e.g.*, the renowned chestnut of Mount Etna). It was early introduced to England, and is one of its most ornamental trees. The timber bears a striking resemblance to that of the oak, which has been mistaken for chestnut; but it may be distinguished by the numerous fine medullary rays. Unlike oak, the wood is more valuable while young than old. When not more than fifty years old it forms durable posts for fences and gates; but at that age it often begins to deteriorate, having ring-shakes and central hollows. In a young state, when the stems are not above 2 inches in diameter at the ground, the chestnut is found to make durable hoops for casks and props for vines; and of a larger size it makes good hop-poles. It is a native of Asia, North Africa, and North America. In Spain and Italy it is grown for its fruit, in Britain, for ornament. In the south of England in warm seasons it ripens its fruit, from which plants are easily raised. None of the other Continental or American species are cultivated in Britain for their timber.

The Common Sycamore or false plane (*Acer Pseudo-Platanus*, L.), the plane-tree of Scotland, is a large tree naturalised in Britain, though seldom attaining the height of those already mentioned. It withstands the sea and mountain breezes better than most other timber trees, and is often planted near farm-houses and cottages in exposed localities for the sake of its dense foliage. Its wood is valued in turnery, for cups, bowls, and pattern blocks. It produces abundance of seeds, and is easily raised, but it requires good and tolerably dry soil; it will not thrive on stiff clays nor on dry sands or chalks. The Norway maple (*A. platanoides*, L.) is a hardy tree, used as a breakwind in exposed situations on the east coast; but neither it nor the other species from Europe or America seems to deserve cultivation for the sake of its timber. The sugar maple (*A. saccharinum*, L.) forms extensive forests in North America. It has been introduced into Britain for a century, but is rather tender, and requires a dry sheltered situation. It is propagated by imported seeds, and it is doubtful if it can be profitably cultivated in this country.

The Common Birch (*Betula alba*, L.) is a tree of the second rank, worthy of culture in inferior soils and situations, especially as coppice-wood. The spray, in some parts of the country, is sold to the besom-maker, and gives a fair return. The tree seeds freely, and is easy of management. It is often planted in poor soil as a nurse for oak and sweet chestnut. It yields excellent fuel. The wood is used for carving, furniture, and agricultural implements, and in the Highlands of Scotland and Sweden for building material. The bark, covered with a layer of earth, is used in roofing, and baskets and boxes are made of it. The weeping birch forms one of the most beautiful features in Highland scenery. None of the American or Himalayan birches have yet been planted with a view to profit as timber-trees, though cultivated for many years.

The COMMON WALNUT (*Juglans regia*, L.), is mentioned in the earliest British botanical writings, and is supposed to have been introduced by the Romans. It grows well, and ripens its fruit in the southern and midland counties of England; but large trees may be seen as far north as Ross-shire in sheltered places. The fruit is in some years plentiful, but ripens only in the hottest summers. The timber is excellent, and held the first place for the manufacture of furniture till the introduction of mahogany, and on this account the tree merits more attention. It is raised from the nuts, like horse chestnuts; the seedlings should be protected from frost during the first winter. The rate of growth is not rapid, and a deep soil is essential to success. If cultivated for the fruit, the seedlings should be transplanted once or twice.

The ROBINIA or false acacia (*Robinia Pseud-Acacia*, L.) is a tree of unquestionable beauty, and much has been written of the value of its timber. It was introduced from North America in the 17th century, and has been extensively cultivated as an ornamental tree. In 1825 Cobbett strongly recommended the planting of it for its timber. It has been used largely in England for hop-poles, and in France for vine-props. In America it is much used for trenails or wooden pins for bolting ship timbers. It is now planted sparingly, the English summer not being sufficiently long and warm to ripen the shoots. The tree is readily produced from imported seeds, and occasionally from suckers, which are abundant. It should be planted in sheltered situations in dry friable loam. It grows rapidly the first few years, but the trunk in Britain rarely exceeds 1 foot in diameter.

Amongst hard-wooded trees of the third rank, the timber of which is useful, are *Cerasus sylvestris*, the wild cherry or gean; *Cratægus Oxyacantha*, white thorn; *Pyrus aucuparia*, mountain ash or rowan; *P. Aria*, white beam tree; *P. Malus*, crab-tree; *P. communis*, wild pear; *Ilex Aquifolium*, holly; and *Cytisus Laburnum*, laburnum. A plantation formed solely of any of these trees is not to be recommended, but when they are self-sown or introduced by way of variety or ornament, it is well to know that their timber is of some value; the laburnum, yew, and holly are the most valuable of the trees of the third rank.

3. *Soft-wood Trees.*

The soft-wood trees are remarkable for the rapidity of their growth, the lightness and whiteness of the wood, and often for their early decay. Among those worthy of cultivation in Britain for timber, are the poplar, willow, alder, lime, and horse chestnut; the two first being those that are generally recommended with a view to profit.

Of the POPLAR (*Populus*, L.) there are numerous species, and several deserve culture for their timber in situations where the soil is good and deep, and where the roots can reach running water; but they do not thrive in stagnant marshes. The following are the best adapted to our climate:—*P. alba*, abele or white poplar, is widely distributed over Europe, and is extensively cultivated in Britain. *P. canescens*, the grey poplar, is classed by Hooker as a sub-species. These trees attain a large size, giving long clean, straight timber, which induces planters to grow it, especially near factories, where the wood is used for flooring, machinery, &c., as it does not easily ignite. The timber is soft, white, and light. The root throws up strong suckers, which always replace trees cut down. *P. tremula*, the aspen, produces a white wood, which is much sought after for the manufacture of paper, and on that account it is rising in value. *P. nigra*, the black or Lombardy poplar, is much planted on the Continent in hedgerows, and also in Kashmir—where the pyramidal variety is common. The wood, which is white, soft, and light, is used for sabots, but is not good for fuel. The bark is used by the tanner. The black Italian poplar (*P. monilifera*) is always propagated by cuttings of the young wood. It pollards well, and is a rapid grower. Poplars should not have large branches pruned off, and they do not coppice well, because moisture enters cracks in their wood.

The WILLOW (*Salix*, L.) is an extensive genus, found in Europe, Asia, and North America, including all the shrubby osier species used for basket-work, as well as a few trees. The arborescent willows are most useful trees, and well merit the attention of planters. They are invaluable for fixing the banks of rivers and canals, and are successfully used for that purpose. As coppice woods with short rotation, they are grown in osier beds, and cut annually for basket-work, or when three or four years old, for hoops, &c., and in this way they yield a good return. The laying down and treatment of osier beds may be seen in great perfection on the banks of the Thames. The wood is used for carving and other purposes. In North America, fishing nets and lines are made of the inner bark. All the species are easily propagated by cuttings, and require to be grown in damp soil. There are three species attaining the size of trees—*S. alba*, the white or Huntingdon willow, reaches a larger size in twenty or thirty years than any other British tree except *Populus alba*, and often yields 1 foot of solid timber for every year of growth. *S. caprea*, the goat willow or sallow, occurs generally as a large shrub, but attains 40 or 50 feet in height. It forms a good protection in maritime situations, but often by its exuberant growth injures more valuable trees. The third tree is *S. fragilis*, the crack willow, and its sub-species *S. Russelliana*, the Bedford willow. Another tree willow, *S. babylonica*, or weeping willow, a native of Russia and China, is very ornamental on islands and river banks. The larvæ of several nocturnal Lepidoptera feed upon the leaves of the willows, and the trunk of the sallow is often injured by the perforations of the *Trochilium crabroniforme* (Lunar Hornet Sphinx).

The ALDER (*Alnus glutinosa*, D.C.) is an indigenous tree met with commonly on the banks of streams, but of smaller size than the poplars and tree willows; it often, however, attains to 40 or 50 feet. It is readily propagated by seeds, but throws up root suckers abundantly. The alder is important as coppice-wood on marshy ground. The wood is soft, white when first cut, and turning to pale red; the knots are beautifully mottled. It is adapted for piles in embankments and bridges; and charcoal of alderwood is valued in the manufacture of gunpowder.

The LIME TREE (*Tilia europæa*, L.), is a beautiful leafy tree with wing-like bracts, much prized for ornament, and suitable for avenues. It is much planted along streets and promenades, affording a pleasant shade during summer; the blossoms are fragrant, and yield most delicate honey. The lime is generally propagated by layers. Its wood, which is very light and soft, is used by saddlers, shoemakers, glovers, and toy-makers; and for carving and modelling purposes, it is superior to all other British trees. Several American lime trees have been introduced, and appear well deserving of a place in our arboricultural collections.

The Common Horse Chestnut (*Æsculus Hippocastanum*, L.), cultivated in Europe since the 16th century, is an ornamental tree of quick growth in good soil. Its handsome blossom surpasses that of all other British trees, and its massive foliage is effective, but the timber is of an inferior quality, only used for boarding and packing-cases, linings of carts, and wheel-barrows. It is rarely planted in mixed plantations where profit is an object; it interferes with its neighbours, and occupies too much room. It is generally introduced near mansion-houses for ornament and shade, and the celebrated avenues at Richmond and Bushy Park are at the time of flowering objects of great beauty. From the crop of nuts which ripen in October seedlings are easily raised, and should be placed in rich loam, and transplanted before being finally planted out.

Roadside Trees and Hedges.

Little attention is paid to the planting of trees along roadsides, and in such situations healthy or well-shaped ones are seldom seen. A pit should be made of sufficient size (2 to 3 feet square), and filled with good soil mixed with rotten dung. The plants require to be fenced, and for the first summer occasionally watered, and the earth dug and kept clear of weeds. In forming avenues on boulevards, the trees should be planted 30 feet apart, and if space allows of it, there should be a double row to form a shady arch for pedestrians. The oversight of these is sometimes given to the surfaceman, or to a man appointed for the purpose, and it should be his duty to maintain the avenues complete. Trees, especially in or near large towns, are subject to injuries which disfigure their appearance or retard their growth, and not unfrequently destroy the plants. To prevent this it is customary to surround the stem with a cradle, or matting, or thorny branches.

Hedge-plants are of great importance both for shelter and protection of plantations. By far the best for outside hedges are the common hawthorn and the wild crab. The sloe or black thorn makes an excellent hedge; but it throws up many suckers, and requires constant attention to keep it within bounds. It forms, however, an excellent barrier for picturesque plantations, where it is allowed to spread itself in every direction. Holly and yew hedges are suitable for inner enclosures. The holly forms an excellent hedge, both for gardens and fields, as its leaves are rarely injured by insects; and, being an evergreen, it harbours neither weeds nor vermin at its roots. Birds are also much less apt to build in it than in deciduous hedges. It has two disadvantages, viz., the slowness of its growth, and imperviousness to wind in the winter season. Were holly hedges occasionally introduced among those of the common thorn, they would add greatly to the beauty of the country in winter. The common furze sown on the top of a bank forms an effective hedge in a short period, but it is not durable. In moist soils, willows or poplars, and in situations exposed to the sea-breeze the elder, may be planted; but such hedges can be hardly considered as fences from want of compactness and density of foliage. The land for hedges should be carefully prepared and freed from weeds before planting, and the expense of doing this will be well repaid by the growth of the hedge afterwards. The ground should be cleared of weeds two or three times a year until the plants have reached some height. Hedge plants should not be pruned till after three years, or they will become stunted; after that pruning should take place once a year. A hedge one-third beech and two-thirds hawthorn is excellent for high and cold situations.

Coppice.

Coppice or Copse consists of self-sown or planted trees periodically cut before they attain the size of timber. This system of wood cropping was more extensively adopted thirty years ago than it is now, as the value of oak bark is much reduced owing to the introduction of foreign bark and other substances for tanning. One requisite for copse woods is that they should spring up freely from the cut root. Most of the broad-leaved trees and shrubs may be cultivated as coppice wood; in soft, wet soils, birch, alder, and various willows are amongst the most useful trees, and in drier soils the oak, chestnut, and ash are valuable for this mode of cultivation.

Ornamental Trees and Shrubs.

As already observed, we exclude from consideration in this article flowering and fruit-bearing trees and shrubs. We also exclude all those that require special protection, and confine ourselves to trees and shrubs considered ornamental from their general form, and suited for introduction into plantations in most parts of Britain. These are arranged under the heads of evergreen and deciduous.

Evergreen Ornamental Trees and Shrubs.—The climate of Britain enables us to cultivate many evergreens; new species are imported, and varieties are produced by accident or experiment, so that the number is always increasing. All the pine tribe may be described as highly ornamental, and many of them endure the open air in the coldest parts of Britain. The Deodar (*Cedrus Deodara*) naturally grows in compact forests, clearing itself of side branches like the larch; in this country single specimens have been extensively planted of late years for ornament. Large quantities of seeds are annually imported from the Himalaya, and it is also raised from cuttings. The Lebanon and Atlas cedars (*Cedrus Libani* and *atlantica*) are closely allied to the Deodar; and it is proved by Hooker that they cannot be separated by constant specific characters. The Atlas cedar is distinguished by a stiff erect leader, and the foliage is generally dark, that of the Deodar being light or bluish green. *Cryptomeria japonica*, the Japan cedar, is a beautiful evergreen tree, attaining 100 feet in height, with a pyramidal head; it yields cones abundantly. *Sequoia gigantea*, the Wellingtonia or mammoth tree, remarkable as the loftiest tree known, attains 300 to 330 feet in height, and 80 to 100 feet in girth, and is a handsome and symmetrical tree. *S. sempervirens*, the redwood of California, is another giant tree, though of smaller size. Both species are hardy in England, and are easily raised from cuttings.[1] The Weymouth pine (*Pinus Strobus*) is a hardy ornamental tree, introduced in 1705, suited for cold situations; and still more so is the *Pinus Cembra*, which is of slow and erect growth and long retains the beauty of youth. *Pinus excelsa* is a hardy and ornamental species, from the Himalaya; but when exposed to wind it does not thrive. It is inclined to seed rather too early and freely in this country. Some of the Californian and British Columbian pines are hardy and ornamental, particularly *P. ponderosa*, the heavy-wooded pine; but it is easily blown over by the wind. Other species are *P. Sabiniana*, *insops*, and *Murrayana*. The Douglas fir (*Abies Douglasii*, Lindl.) is a handsome tree, as hardy as the common spruce, differing in the dark green colour, and apparently intermediate between the common spruce and the silver fir. It was introduced in 1827, and is of very rapid growth in England and Scotland. At Dropmore there is a tree which, at the age of 44 years, was 100 ft. high, with 9 ft. 7 in. girth at 3 feet above the ground. Many specimens in Perthshire raised from layers and cuttings since 1846, are 50 to 70 feet high. The

[1] An interesting paper "On the *Wellingtonia gigantea*," containing a table of the growth of this tree on various soils in different parts of Britain, by Mr Hutchison, is published in the *Trans. High. Soc. of Scot.* 1873.

black and white spruces (*Abies nigra* and *alba*) of North America are well-known ornaments in our pleasure grounds; and there are some Californian species, such as *Abies Menziesii*, *nobilis*, and others, which are hardy, and promise to be valuable additions to our ornamental trees. The Hemlock spruce of Canada (*Abies canadensis*) is hardy throughout North Europe. The Cephalonian fir (*Abies cephalonica*, Loudon), closely allied to and probably only a variety of the silver fir, is a handsome tree, readily propagated by cuttings and from cones imported from the Mediterranean. *A. Nordmanniana*, Link, a stately tree with dark, compact foliage, and ovoid cones, of late years much cultivated in England, forming forests in the Crimea and the Caucasus, is regarded as a variety of the silver fir by Parlatore and Grisebach. *A. Pinsapo*, Boissier, is a beautiful tree with rigid whorled branches, introduced from Malaga and Algeria; it is much cultivated in England, and thrives well. *Abies Smithiana*, the Himalayan spruce, closely resembles the common spruce, and is hardy in England and Scotland, where it grows with great vigour; it is readily propagated by cuttings, and by grafting, and British trees already produce cones. *Abies Webbiana*, Lindl., the Himalayan silver fir, suffers in spring in North Europe, because it starts into growth too early: it is grown in Ireland and the south-west of England. The Chili pine (*Araucaria imbricata*), a noble tree in its native country, and a conspicuous object in a park from the peculiarity of its whorls of rigid branches, is hardy in many situations in Scotland as far north as Dunrobin. *Cupressus Lawsoniana*, introduced in 1854 from California, is hardy, and rapidly becomes a handsome tree, ripening its cones. The common cypress (*Cupressus sempervirens*, L.) grows vigorously in the central districts of England, but scarcely thrives in the northern counties. *Cupressus glauca* or *lusitanica*, L., is a beautiful evergreen, with glaucous foliage, but tender; nevertheless, in Ireland it attains a great size. The Ginkgo or maidenhair tree (*Salisburia adiantifolia*, Sm.) is remarkable for the singularity of its foliage; it is a native of China, but is hardy in many parts of England. *Biota orientalis*, Endl. (syn. *Thuja orientalis*, Linn., the *Arbor vitæ*), is a small evergreen tree, indigenous in Japan and China, much cultivated in Europe, with foliage similar to that of the Cypress. The red cedar (*Juniperus virginiana*, L.), the Phœnician, and other species of juniper, are hardy and ornamental. The holly, boxwood, evergreen oak, and Portugal laurel are universally known and admired, and their glossy foliage makes them specially beautiful in winter.

Deciduous Ornamental Trees.—We can name only a few of the most prominent deciduous trees planted solely for ornament. *Magnolia grandiflora* is grown chiefly on walls, as it suffers from wind. Its flowers and foliage are very beautiful. The tulip tree (*Liriodendron tulipifera*, L.) forms a tree of the first rank in the climate of London, and attains a large size in the milder parts of Scotland; for the beauty of its foliage and flowers, it deserves a place in every collection. *Pavia indica*, the Himalayan horse chestnut, is smaller than the common horse chestnut, but extremely beautiful from its large panicles of variegated blossoms. There is a fine specimen in the Edinburgh Botanic Garden. *Kœlreuteria paniculata*, a native of China, is a hardy tree, very ornamental from its foliage as well as its flowers. There are fine specimens both in England and Ireland, yet the tree is not generally met with in pleasure-grounds. The ailanto (*Ailanthus glandulosa*), a Chinese plant, is hardy in England. It forms a stately tree with a straight trunk and magnificent foliage, the leaves being sometimes 3 feet in length. In some parts of France it is planted as a timber-tree, and thrives well on chalky soils. The bladder-nut tree (*Staphylea*, L.) may be trained to be a handsome low tree, ornamental from its foliage, white flowers, and curious bladder-like capsules. There are two species—*S. trifolia* and *S. pinnata*. The common spindle tree (*Euonymus europæus*) and the broad-leaved spindle tree (*E. latifolius*), when trained up to single trees on a deep loamy soil, with ample space, form in autumn, when their capsules are ripe, remarkable and striking objects. The winter-berry (*Prinos glaber*) is a deciduous shrub, a native of North America, which, like the holly, produces fine scarlet berries, and retains them through the winter. There are several species, all hardy, and worthy of a place in our collections. *Sophora japonica* forms a splendid tree in the climate of London, and a pendulous-branched variety is very ornamental. In dry and warm seasons, when the leaves of most other trees become of a paler green than usual, those of this tree assume a darker hue. *Virgilia lutea* is a North American tree, with fine large foliage, hardy in most parts of Britain; and, in America, valued for the yellow colour of its wood. The laburnum has already been mentioned as a useful and ornamental tree. The genus *Cratægus* consists of many species and a vast number of varieties, among which are many beautiful small trees, remarkable for an irregular picturesque outline even at an early age. They flower and fruit profusely; the flowers are generally white and fragrant, but some varieties are tinged with red and purple; they appear from March to July, and the Glastonbury thorn blooms at Christmas. *Cotoneaster frigida*, *bacillaris*, *acuminata*, *microphylla*, and *nummularia* are small trees of great beauty, both on account of their foliage and their fruit. They are from the Himalaya, and hardy in England. They are cultivated in a variety of forms, some of which have been described as distinct species. The wood is hard and elastic. There are many ornamental species and varieties of the genus *Pyrus*, which now includes species formerly grouped under *Sorbus*, *Mespilus*, &c. From the Himalaya we have (*P. variolosa*), a remarkable tree, with leaves sometimes like those of the common pear, and at other times lobed or pinnatifid. *P. Aria*, the white-beam tree, and all its varieties, deserve culture, as compact small trees, remarkable for their large woolly foliage, which dies off a fine yellow, their white blossoms, and showy red fruit. The service tree (*Pyrus Sorbus*) and its varieties are very ornamental. *Pyrus japonica*, L., is well known as one of the most ornamental spring-flowering plants in cultivation. *Hamamelis virginica*, the Wych hazel, is valuable from its beginning to flower in November, and retaining its blossoms till February or March: though rarely seen in collections, it is hardy, and forms a handsome small tree. The snow-drop tree (*Halesia tetraptera*) is one of the hardiest of North American trees, and, when in flower, one of the most beautiful: it ripens abundance of seeds in this country, by which it is readily propagated; in some parts of England it is, like the American bird-cherry, naturalised in the copses. It is rarely met with in Scotland, though few ornamental trees are so well adapted for the climate. The date-plum (*Diospyros Lotus*) though it ripens fruit as a standard near London, is tender in the northern counties. The Virginian snow-flower or fringe tree (*Chionanthus virginica*) is nearly as hardy as the snow-drop tree; and when planted in a moist soil and trained to a single stem, its head is ornamental from its large deep-green foliage, independently of the fine, white, fringe-like flowers, which are suspended from the axils of the leaves. The common purple and white lilacs (*Syringa vulgaris* and *S. vulgaris alba*) are hardy, and make neat small trees when trained to a single stem. The weeping-ash (*Fraxinus excelsior*, var. *pendula*) is well known. It suffers much from cattle or sheep browsing on the pendulous branches, disfiguring the plant, which should always be enclosed.

The flowering or manna ash (*Fraxinus Ornus*), a native of the mountains of South Italy, is a handsome tree, deserving a place in ornamental plantations. It has a fine effect standing singly on a lawn. The medicinal manna it yields is obtained by making incisions in the stem. *Catalpa syringæfolia* is a splendid tree when in flower: it attains the height of 30 or 40 feet, and sometimes ripens its seeds in the climate of London; but in the northern counties it seldom does much good. It bears a very severe cold in winter, provided there has been heat and sunshine enough in summer to ripen its wood. Of the genus *Quercus*, 281 species, European, American, and Asiatic, are described in De Candolle's *Prodromus*, and a great variety are procurable in British nurseries. The best known European species are *Q. Suber*, the cork oak; *Q. Cerris*, the Turkey or mossy cupped oak; *Q. Æjilops*, the Vallonea oak; and *Q. lusitanica infectoria*, the gall or dyer's oak. The Lucombe and Fulham oaks are believed to be hybrids between *Q. Cerris* and *Suber*. *Q. Ilex*, the evergreen or holm oak, a native of South Europe, Persia, and the North-West Himalaya, but introduced into Britain in 1581, and commonly planted, attains a large size, and frequently ripens its acorns. The oaks of North America are very numerous and interesting, but they do not ripen their shoots sufficiently to be frost-proof. None of the deciduous Himalayan species have yet been successfully introduced.

Propagation and Culture in the Nursery.

Nursery Culture.—A nursery is a plot of ground devoted to the propagation and rearing of trees; it should as far as possible be exempt from the influence of frost, which prevails in low situations, and it ought to contain a variety of soils. As a general principle, all seeds will germinate in any soil provided it contains vegetable matter, and is friable, free of stones, and well drained, with a convenient supply of water. If a nursery therefore contains the three leading soils, sand, loam, and peat, it will suffice for all required purposes. With regard to climate, all deficiencies which occur in Britain may be met by glazed frames for raising the more tender kinds. It is the interest of the nurseryman to have his nursery in a fine climate, and in deep fertile soil, that he may raise large vigorous plants in the shortest period; but it is the interest of the purchaser to have the plants reared in a climate and soil inferior to that into which they are to be transplanted, because, when this is done, instead of the plants receiving a check, as is usually the case, they will be improved by transplanting. The strength of a plant and its suitableness for successful transplanting consists in all its parts being developed, in the thorough ripening of its wood, and in the dormant state of its fibrous roots. If by any mode of culture these requisites can be obtained, together with the long and thick shoots which are produced by growing the plants in deep rich soil, so much the better; but in the climate of Britain trees reared in nurseries with inferior and unmanured soil are likely to prove most hardy. Those who plant in mountainous districts will always find it better to have their nurseries on the sides of mountains than in the valleys.

Propagation.—Trees are chiefly propagated by seeds, but also by cuttings, layers, budding, and grafting. The timber-trees of all countries are raised from seeds, with a few exceptions, such as the poplar and willow, which are raised from cuttings, and some species of elm, lime, and a few others, which are raised from layers or by grafting. Most ornamental trees are raised by some of these artificial methods, because in this country they seldom ripen seeds. Thus, all the American oaks may be grafted on the common British oak. Most of the foreign maples and birches are raised by layers, most of the ornamental thorns by budding and grafting, and willows and poplars by cuttings. All plants which do not ripen seeds readily are propagated artificially, and that mode is preferred by the nurseryman, which experience has proved will produce the largest and most vigorous plants in the shortest time. Thus, though more suitable plants would be produced by raising the plane and poplar from cuttings, because in that case nature would adjust the tops to the power of the roots, yet as much larger plants are produced by layers, that mode is preferred in commercial nurseries. The lime tree and English elm ripen their seeds in Britain, but large plants are much more rapidly procured in the first case by layers, and in the second by grafting: the mode by which the largest plants are most rapidly produced need not always give way to the slower method; but in most cases, it would be advantageous to the purchaser that the slower mode should be adopted. According to some writers, seedling plants are of greater durability than those raised in any other way; but though this may be true in some cases it is not universally applicable, as we know that a bud produces as perfect a plant as a seed; the only difference being that the bud seems more fully imbued with the peculiarities of the individual which produced it than the seed. The poplar, willow, vine, &c., have been propagated by cuttings from time immemorial, and appear to possess respectively the same properties now that they did in the days of the Romans. Seeds should be collected when mature from the best specimens; and should either be sown immediately, or preserved in a place where they will undergo few atmospheric changes till the proper sowing season, which in most cases will be the following spring. Nature, it may be observed, sows all her seeds soon after they are matured; that is, they drop from the tree upon the ground in autumn or the beginning of winter, or, in the case of some trees, such as the conifers, not till spring; but when seeds are thus left to sow themselves many are destroyed by animals, many fall in unfavourable positions for germination, and only a small proportion produce plants. It is for the arboriculturist to study nature's mode of sowing, and to imitate only her favourable features. The greater number of seeds may be stored till the following spring, that is, till February or March, and then be committed to the soil. Poplar and willow seeds, however, ripen early, and when sown immediately on dropping from the tree, often come up in the course of a few weeks; whereas, if they are kept till spring, the greater number do not come up at all; and seeds which lie two years in the ground before coming up, such as those of the hawthorn, the holly, &c., may be kept till the second spring before they are sown.

In order to show the treatment required for different kinds of seeds, and the plants raised from them, it will be convenient to throw them into the following groups:—Trees producing (1) cones; (2) nuts, acorns, masts, or keys; (3) cottony or feathery seeds; (4) fleshy fruits; or (5) leguminous seeds.

Coniferous Trees.—Coniferous trees ripen their seeds from October till January, and if the cones remain on the tree throughout the winter the seeds do not generally drop out till April or May; such as drop into favourable soil come up in five or six weeks. The cones should be collected immediately after they are ripe, and laid in a dry place. The seeds are extracted by exposing the cones to the heat of the sun under glass, or by subjecting them to artificial heat before an open fire, or on a kiln. The seeds are sown in April, in soil dug over and finely raked; and then covered with a thin coating of soil. The beds, after the sowing is completed, should be shaded from the sun by branches of tree. In cold moist climates, such as that of Aberdeen, this shading may be dispensed with;

but in the climate of London it is in most seasons necessary, and may be effected by mats, straw, or evergreens. For convenience, the seeds are generally sown in beds, a slight excavation being made by drawing some of the earth to the sides; and in order that the seeds may be evenly deposited on a somewhat firm surface, the bottom of this excavation is lightly rolled. After the seeds are scattered over the beds they are again rolled, and the covering of earth thrown over them. It is found that the rolling of the beds before and after sowing, by bringing the seeds into close contact with the soil, accelerates germination. The more tender pines are sown in pots or flat earthen pans, for the convenience of making them germinate under glass, and to facilitate future transplantation; but the process of sowing is exactly the same. The seedlings require nothing but the usual culture of the nursery for two summers; after which they should be transplanted where they are finally to remain; or they should be planted in the nursery in lines, or scattered over beds; in either case they should be 3 to 6 inches apart, according to their height and the length of the leaves. For the Scotch pine and spruce fir, which grow slowly when young, 3 inches are sufficient; for the larch, which grows rapidly, and for the pinaster, which has long leaves, 6 inches are required. Here the plants may remain two years, and afterwards be again transplanted; unless they are in the meantime removed to where they are to remain, which, to ensure good timber trees, should be done before young conifers exceed four years' growth.

Trees bearing Nuts, Acorns, Masts, Keys, &c.—These ripen from October to December. Acorns usually in November; but the beech, horse chestnut, walnut, and hazel, ripen their fruit in October, and most of the sycamores and maples in September. All these ought to be gathered as soon as ripe, because the best are liable to be picked up by wild animals as soon as they drop. They may be sown immediately or kept till February, as in neither case will they come up till April or May. The seeds should be sown in a sandy loam, in drills, at such a distance from each other that the leaves of the seedlings may not touch at the end of the first season; they should be gently pressed down into the soil, and covered to twice the depth of the seed. Drills are recommended for this description of tree-seeds that a spade may be inserted obliquely between the rows, so as to cut the tap-root of the plants, and force it to throw out lateral roots. This is commonly done in the spring of the second year, and, by increasing the lateral roots and their fibres, renders the tree better adapted for transplanting. At the end of the second year plants so treated may be taken up, and either planted where they are to remain, or transplanted into nursery lines, at distances suited to the habit of the species. Here they may remain two years longer, and be again replanted. The larger and stronger broad-leaved tap-rooted trees are, up to a certain point, before they are removed from the nursery, the more vigorously will they grow where they are finally to remain. The size to be attained in the nursery must depend on the condition of the soil into which they are to be transplanted. If moisture be so abundant as to supply the fibrils with water during the first summer, even if the removed plant has a stem an inch in diameter, so much the better; it being understood that it has been transplanted in the nursery every two years, and is therefore well supplied with fibrous roots, and has its wood perfectly ripe. If, on the other hand, the soil into which the plant is to be transplanted is dry and poor, the plants should be removed there at the end of the second year, because such plants, being of small size, have few leaves to exhale moisture, and before they grow large they will have adjusted their roots and annual growths to the locality.

Trees with Cottony, Feathery, and other soft Seeds.—The seeds of the genera *Populus, Salix, Alnus, Betula, Ulmus*, &c., ripen from May to November; poplars in May; willows and elms in June; alders in November; and birches in October. The seeds of the alder and birch may be kept in a cool, dry, airy situation till spring, or sown immediately after they are gathered. They come up in the May or June following; but the seeds of the elm, poplar, and willow should be sown immediately. Many will come up the same autumn, and the remainder the following April and May. The seeds may be dried and preserved in bags for a year; but in this case the greater part will not vegetate. Poplar and willow seeds require to be sown on a surface rendered level and slightly firm by rolling. After the seeds are equally distributed over it, they should be covered with light sandy soil, or vegetable mould, no thicker than barely to conceal the seed. After this the bed should be watered and shaded and kept uniformly moist by occasional watering when the plants make their appearance. Of all seedling trees raised in British nurseries, none grow with so much vigour the first year as the common elm; and, therefore, the seeds of this tree require to be placed at a greater distance from each other than those of any other kind. The seeds of the elm keep better till the following spring than those of the poplar and willow.

Trees with Fleshy Fruits.—The fruit of the genera *Pyrus, Cotoneaster, Viburnum, Cratægus, Ilex, Prunus, Cerasus, Rhamnus*, &c., ripens from August to December. It should be gathered when ripe, mixed with sand, and laid in a heap till the pulp rots away. With some species the seed may be sifted from the sand and sown in the following February, the seedlings being treated as the seedlings of the conifers. In others the heap may be left for two years, and many of the seeds will not germinate till the third spring.

Trees with Leguminous Seeds.—These include the genera *Cytisus, Acacia, Robinia, Gleditschia, Caragana*, &c. The pods generally ripen in September or October, but some not till November or December. The seeds may be kept in the pods till February, and then sown in beds, as described. At the end of two years the young trees may be transplanted.

The Formation and Management of Plantations.

Whether plantations of forest trees should be sown or planted, is a question which has been much discussed. It is readily allowed, that sowing is the natural mode; but man tries by art to supplement nature, and to obtain a higher rate of production by skill and labour. Some indeed have asserted that the timber of transplanted trees is never so valuable as that of sown ones, the reason alleged being, that the transplanted trees have lost their tap-roots. On examining the roots of full-grown trees, however, no tap-root is ever found; on the contrary, those roots which proceed either directly or obliquely downwards from the base of the trunk, are uniformly much smaller than those which proceed horizontally, a few inches below the surface of the ground. The tap-root, therefore, is chiefly of use to the tree whilst young, and is larger in proportion to the part of plant above ground, in the first year, than in any succeeding year; and as the top of the tree and the lateral roots increase in size, the tap-root ceases to increase, till in ten or twelve years' growth, it is found to be the smallest of the main roots of the tree. We assume, therefore, that a transplanted tree, other circumstances being the same, is in all respects as good as a seedling. Hence we conclude, that all artificial plantations ought, in the first place, to be made by planting, and at regular distances. We would carefully prepare the soil for the trees, removing the weeds afterwards for two or three years till the branches begin to cover the ground; in which state we should leave it during the growth of the plantation, only taking care to remove large weeds. This kind of tree culture, however, can only take place with advantage, on a tolerably level surface, where the soil is of the same nature throughout. Not to speak here of grounds destined for ornamental plantations, the great majority of plantations formed with a view to profit are necessarily on hilly and unculturable surfaces, and where there is probably a variety of soil, even in a limited space. The preparation to be given in such cases is under-draining; for to dig or trench the surface would render it liable to be washed away by heavy rains and thawing snow. Plantations under such circumstances must be formed by digging pits for each tree, and by selecting such kinds as are best adapted to the locality. This frequently occasions the use of a variety of trees in the same plantation, causing a more picturesque effect in the landscape and a more advantageous result in the production of timber. We have already stated that coniferous trees should be transplanted before they are four years old; but that broad-leaved trees may be moved at four, six, eight, or ten years' growth; provided they have been transplanted every two years in the nursery, and that the soil is sufficiently deep and moist to bring the fibrous roots into full action the first summer. When strong plants of this kind are used they overcome the natural herbage immediately; and, if carefully planted in good soil, not one in a score will fail. Smaller plants, on the other hand, are apt to be choked by herbage, and to have their leaves and young shoots injured by insects. In a dry soil and subsoil, plants with a mass of roots cannot subsist the first year; and therefore smaller plants, once transplanted, are preferable. There are circumstances under which sowing is perhaps the only mode of forming plantations that can be adopted: as for example, in the dunes of Gascony, which by nearly a century of regularly continued sowings have been almost entirely transformed from drifting sandy wastes into forests of the cluster pine. In making plantations of this pine we should prefer sowing several seeds in every place where a plant was intended to remain, unless we could procure a sufficient number of plants of two years old in pots. If more than one came up, the rest should be removed the second or third year; and while the plants are young care must be taken that they are not choked by herbage. When steep rocky cliffs or stony hill-sides are to be covered with wood, sowing is the only mode that can be resorted to; the kinds of seeds to be sown may be selected according to the nature of the debris or the soil in the clefts of the rocks. Where the soil is good, broad-leaved trees may be introduced; but where it is poor, the Scotch fir, larch, birch, mountain ash, and white beam tree are most suitable. Where there is no visible soil, two or three seeds, enveloped in a composition of moss, cow-dung, and loam, may be deposited in crevices, or among loose stones; acted upon by the rain, the seeds will vegetate, and find nourishment in the fragments of the ball in which they were enveloped.

Two important points connected with the formation of plantations are the distances at which trees should be planted, and the use of nurse-trees. As the strength of a plant depends on the number of its leaves, and their full exposure to light, it follows that the strongest young trees will be those which are clothed with branches and leaves from the ground upwards, and which have their leaves fully exposed on every side to light. The distance from each other at which trees should be placed in a plantation depends on the size and nature of the plants, and the soil, and situation. To have tall and straight stems, the trees are planted thickly (conifers more so than other kinds), about 4 to 6 feet apart; but when the lower branches of the plants interfere with one another, thinning should be commenced and continued from time to time. When the lower tier of branches shows symptoms of decay they should be removed by cutting close to the stem. This process of pruning has been condemned by many, particularly in soft-wood trees; but if practised early and judiciously it may be attended with benefit, especially when the part removed does not exceed an inch in diameter, or as long as the operation can be performed with an ordinary pocket-knife; the wound will heal quickly, and leaves no mark. If branches are allowed to remain till they are 3 or 4 inches in diameter, and are then cut off at some distance from the bole (snag-pruning) the timber deteriorates, the wound heals over in time, but the timber is either knotty or unsound. Close-pruning is performed by sawing off a branch close to the trunk or a leading branch. When the wound is large, a dressing should be applied to exclude air and moisture. For this purpose linseed oil, or three parts cow-dung and one part powdered lime, will be found useful. In the Royal Forests of England the branch of an oak is never removed unless special circumstances require it. Long experience has justified this system. Lateral branches which are growing with over luxuriance, and attracting too much of the sap of the plant, should be foreshortened, just as the lateral branches of a hedge are clipped when they extend too far. The only objection to this method of pruning is the amount of labour it entails. Mr M'Nab of the Royal Botanic Garden, Edinburgh, has recently urged the advantage of stem-pruning of conifers, on the grounds that it encourages a free growth, and tends to make the trees hardy by exposing the bark of the stems to the freer action of the air. Stem-pruned trees also are less likely to be broken by a weight of snow lying on the branches.

For pruning, the following tools are required,—a pocket knife, hand-saw, chisel, and pruning shears; the two last are fixed on long poles. Thinning, carried out with care from time to time, is of the greatest consequence. The removal of weak and crooked supernumeraries prevents unnecessary exhaustion of the soil, while it admits the essential agents, air and light, which favour the expansion of lateral branches. If, however, the trees be thinned out too widely, the side branches become robust and the stem is not drawn up. The rule in thinning should be, to keep the trees clear of each other, so that the branches do not interlace, and the air circulates all round. The time when thinning should commence depends on local circumstances, and the species under cultivation. In a well-managed plantation the proceeds of thinnings in twenty years should go far to cover the expense of culture and interest of capital.

The next point to be considered is that of introducing nurse-plants into plantations. That these have a tendency to accelerate the upward growth of trees for a number of years there can be no doubt, but it is at the expense of the side branches and leaves. Evergreen nurses, such as the Scotch, silver, and spruce firs, improve the condition of a plantation by preventing the radiation of heat from the ground, by checking the growth of herbage, and by protecting the principal trees from high winds until they are thoroughly established in the plantation. The kind of tree which is to form the main crop having been fixed on, and the number that when full grown will stand on an acre or any given surface, they should be planted in their proper places, and the intervals filled up with the nurse-plants. As the nurses grow, and their branches touch the principals, let them be thinned, so as not to prevent the free growth of the principals: this should be done gradually. For example, it is customary to plant oak with coniferous nurses, and in the course of seven to ten years the nurses require a partial thinning to make way for the principal trees; at this date the pines will be fit for poles or rails. It often, however, happens that the nurses are allowed to remain too long, and the principal crop consequently suffers from the evils of overcrowding.

We have now alluded to some of the chief points connected with arboriculture, but the subject is of such extent that it could not be fully treated in the limits of this article. Our object has been rather to direct attention to general principles; and for fuller information we would refer those who desire a more practical and detailed acquaintance with the subject to the following works:—

The classic *Sylva* of Evelyn and the exhaustive *Arboretum et Fruticetum Britannicum* of Loudon should be in the hands of all students of Arboriculture. Selby's *History of Forest Trees*, 1842; *The Forester*, by James Brown, 4th ed., 1871; Grigor's *Arboriculture*, 1868; Du Breuil's *Cours Elémentaire d'Arboriculture*, Paris; Paradè's *Cours Elémentaire de Culture des Bois*, Paris; Mathieu's *Flore Forestière*, Nancy, 1860; and Hartig's *Lehrbuch für Förster*, Stuttgart, 1861, are all useful books. Prize essays on special subjects are contained in the *Transactions of the Highland and Agricultural Society*, and instructive papers on various practical details are to be found in the *Transactions of the Scottish Arboricultural Society*. The *Forest Flora of Northern India*, by Stewart and Brandis, 8vo, with 4to volume of illustrations, London, 1874, contains a great amount of information on the culture of trees in India and the Himalayan region. For American trees see the *North American Sylva*, by Michaux, Paris, 1819; *Trees and Shrubs of Massachusetts*, by Emerson, Boston, 1846; and *Trees of America*, by D. J. Broune, New York, 1846. (H. C.)

TABLE

Showing the number of Trees required to plant an Imperial or Scotch Acre, at distances of one to thirty feet.

Imperial Acre.				Scotch Acre.			
Distance.	Number.	Distance.	Number.	Distance.	Number.	Distance.	Number.

ARBROATH, or ABERBROTHOCK, a seaport and manufacturing town of Scotland, in the county of Forfar, 17 miles N.E. of Dundee and 60 N.N.E. of Edinburgh, in lat. 56° 33′ N. and long. 2° 35′ W. Of its origin we have no information, but it is probable that the shelter of the river Brothock, from which it derives its name, early attracted a settlement of seafaring folk. It was certainly in existence before the Tyronensian monks came from Kelso to take possession of the beautiful abbey dedicated to Thomas-a-Becket, which King William the Lion had just founded in 1178. Whether the town was created a royal burgh in 1186, as has been stated, is uncertain; but it still preserves its charter of 1599. By King John of England it was exempted from "toll and custom" in every part of the southern kingdom except London. In 1320 a parliament was held in the abbey by Robert I., and a letter—one of the most remarkable documents of our early history—was addressed to the Pope in regard to the relations between Scotland and England. In 1394 the burgesses of Arbroath entered into an agreement with John Gedy, the abbot, by which he and his successors were bound to maintain a sufficient harbour at their own expense. The abbacy was held in succession by Bishop Beaton of Glasgow, and his nephew, Cardinal Beaton, afterwards Archbishop of St Andrews. It was abolished by Act of Parliament, and erected into a temporal lordship of the Hamilton family in 1541. There is a tradition that the abbey was burned by a neighbouring "laird" in consequence of a private quarrel with the commendatary; but it is more generally believed that it merely fell into ruin from neglect. There is no evidence that it suffered from the attacks of the Reformers. The vestry, the south transept, part of the chancel, the south wall of the nave, part of the entrance towers, the fine Norman gateway, and part of the secular buildings are still standing, and the abbot's house, now called the abbey house, is still inhabited. At the beginning of the 18th century Arbroath was a place of but little importance, but has since gradually risen. It is now the principal seat of the sail-cloth manufacture, has about thirty spinning-mills and seventeen factories, several considerable foundries, tanneries, and other works. During the course of last century the abbot's harbour was superseded by one more commodious a little to the west, which was enlarged and improved, about 1844, at a cost of £50,000. More recently, by means of a Government loan and other funds, amounting together to £35,000, the entrance and bar have been much deepened, and a wet dock is (1875) in course of formation. A neat signal tower, 50 feet in height, with an excellent telescope, communicates with the Bell-Rock lighthouse; and on the north pier is a fixed red light, at an elevation of 24 feet, visible 8 miles off. The imports are flax, hemp, coal, &c.; and the exports, paving-stones, grain, potatoes, fish, &c. At the first of December 1873 the number of vessels registered at the port was 64, with an aggregate burden of 9242 tons. The customs receipts that year amounted to £15,861, 13s. 1d.; the tax on British spirits to £6767, 11s.; total, £22,629, 4s. 1d., showing an increase on the previous year of £604, 14s. 1d. Among the public buildings are the town-hall, a trades' hall, the new hall, the parish church, with a spire 150 feet high, three *quoad sacra* churches, five Free, three United Presbyterian, one Episcopalian, one Roman Catholic, and two Independent. There are six branch banks, a savings bank, a public library, an excellent museum, a high school, five other public and a number of adventure and denominational schools, with an aggregate attendance of 3000 children, an infirmary, and a considerable number of charitable endowments. The municipal government is vested in a provost, three bailies, a treasurer, a dean of guild, and twelve councillors; and there are seven incorporated trades. In the year 1873–74 the expenditure for general public purposes—including paving, lighting, cleansing, but excluding improvements, water, and sanitary expenditure—was £6773, 15s. 3d. The town has been drained and well paved; an additional though somewhat small supply of water has been recently obtained, and the sanitary condition is on the whole satisfactory.

Arbroath unites with Forfar, Montrose, Brechin, and Bervie, in sending a member to parliament. By the census of 1871 it contained 2359 inhabited houses, and, including

179 within the royalty but beyond the parliamentary boundary, 20,170 inhabitants. Of these 3723 are engaged in manufacturing linen fabrics. Arbroath is a station on the Caledonian Railway The market day is Saturday; and fairs are held on the last Saturday of January, the first Saturday after Whitsunday, the 18th of July, if that day is a Saturday, or on the first Saturday thereafter, and the first Saturday after Martinmas. About a mile from the town, at St Vigeans Church, is one of the most interesting of the Scottish sculptured stones, containing what has been held to be the only legible inscription left us in the Pictish language (*Sculptured Stones of Scotland*). See *Statistical Account of Scotland*; vol. xi., and local histories.

ARBUTHNOT, John, a celebrated physician, wit, and man of letters of the age of Queen Anne, was born at Arbuthnot, near Montrose. The date of his birth is somewhat uncertain; many authorities give 1675, which is scarcely reconcilable with his first appearance in London; it should probably be 1665 or 1667. His father was a clergyman of the Scotch Episcopal Church, who was compelled by the Revolution to resign his charge, and whose family were consequently dependent on their own exertions. Young Arbuthnot studied at the University of Aberdeen, where he took the degree of M.D. He proceeded soon after to London, and for a time supported himself there by teaching mathematics. His first published work was a translation, with considerable additions, of a treatise by Huyghens, called *Of the Laws of Chance, or a Method of Calculation of the Hazards of Game*, 1692. About this time there was much speculation concerning the geological formation of the earth, and Dr Woodward published an Essay towards a natural history of the earth, in which some curious views were propounded with regard to the deluge. This essay Arbuthnot attacked with great success in his *Examination of Dr Woodward's Account of the Deluge*, &c., London 1695. By this work he was brought into prominent notice, and not only gained means to extend his practice, but at the same time brought himself into connection with the circle of wits and literary men who formed the chief glory of the age. He followed up the work on Dr Woodward by another on the usefulness of mathematical learning, and contributed to the Royal Society an interesting memoir, called *An Argument for Divine Providence drawn from the Equal Number of Births of both Sexes*, which procured him, in 1704, admission as a Fellow to the Royal Society. A year later appeared the first edition of a larger work, *Tables of the Grecian, Roman, and Jewish Measures*, &c. This is still a work of some value, though in many parts superseded. It was held in considerable estimation on the Continent, and was translated into Latin. About this time a happy accident introduced Arbuthnot to Prince George of Denmark, who was seized with sudden illness when on a visit to Epsom. Arbuthnot, who chanced to be there at the time, was called in, and ever afterwards continued to be physician to the prince. In 1705, at the especial request of the Queen, he was made her physician extraordinary, and four years later he became Royal Physician in ordinary. In the same year he was elected a Fellow of the Royal College of Physicians. He was now in the very centre of the literary society of the time, and in it his great talents, massive learning, and brilliant wit enabled him to take a prominent place. He was on terms of close intimacy with Pope, Swift, Gay, and Parnell, and quickly became one of the foremost literary men of the Tory party. In 1712 appeared the celebrated political allegory, called the *History of John Bull*. The object of this admirable piece of satire was to throw ridicule on the duke of Marlborough, and to excite among the people a feeling of disgust at the protracted war then being carried on against Louis of France. The nations at war are represented as tradesmen involved in a lawsuit: the origin of the dispute is traced to their selfish and narrow views; their national characteristics are skilfully hit off, and the various events of the war, with the accompanying political intrigues, are symbolised by the stages in the progress of the suit, the tricks of the lawyers, and the devices of the principal attorney (Marlborough) to prolong the struggle. There have been many imitations of this famous allegory, but few of them have been so happily conceived, or so well sustained. Its immediate effect was very considerable, and it is even now of interest for the lively picture it presents of the politics of the period. At the time of its appearance it was generally attributed to Swift, but passages in Swift's own letters make it quite clear that Arbuthnot was the sole author.

The death of the Queen in 1714 was a severe blow to Arbuthnot. He lost his post as court physician, and was much impaired in his means. He appears about this time to have paid a short visit to Paris, and on his return took up his residence in Dover Street. His correspondence shows that after the Queen's death he was at first disposed to be despondent and gloomy, but he soon recovered his natural buoyancy of spirits, and entered with eagerness into the proposed work of the Scriblerus Club. The principal members of this club were Pope, Gay, Swift, Arbuthnot, Parnell, Harley, Atterbury, and Congreve. The work projected by them, a comprehensive satire on the abuses of human learning, was never completed. One brilliant fragment, the first book of the Memoirs of Martinus Scriblerus, published in Pope's Works, is undoubtedly the work of Arbuthnot, though it is not improbable that some portions are due to Pope and Swift. It is an admirable combination of wit and learning, and is certainly one of the finest pieces of sarcastic humour in the English language. Arbuthnot still continued practice as a physician, and attained great eminence in his profession. In 1723 he was made one of the censors of the Royal College of Physicians, and in 1727 had the honour of delivering the Harveian oration. In 1731 he published an *Essay concerning the Nature of Aliments*, which has been frequently republished, and has been translated into German. In 1733 he wrote an *Essay on the Effects of Air on Human Bodies*. He died in February 1735. The scattered writings of Arbuthnot, on which his reputation as a wit rests, are so interwoven with the works of Swift and Pope, that it is difficult to discover what is absolutely his. A collected edition, *Miscellaneous Works of the late Dr Arbuthnot*, Glasgow, 1750–51, contains many pieces that were expressly disclaimed by the author's son.

ARC, Joan of. See Joan of Arc.

ARCADE (Fr. *arcade*, *arcature*, Ital. *arcata*, Ger. *Bogengang*), in street architecture a covered way or passage, either open at the side with a range of pillars, or completely covered over. The finest arcades of this description are to be found in Paris. Some have open sides, such as those in the Rue de Rivoli, Palais Royal, and Old Place Royal; others, such as the Passages des Panaromas, Jouffroy, and de Princes, are covered passages, and form convenient thoroughfares. A few, like the Passages Choiseul and de l'Opera, are favourite lounges. They are all more or less lined with elegant shops. There are two specimens of covered passage-arcades in London, the Burlington and Lowther, but they are very inferior in style to those in Paris. The arcade which runs round three sides of the Square of St Mark at Venice is the finest of its kind. In Gothic architecture the term signifies a range of arches, supported on columns or piers, and either open or attached to a wall. The word is used in contradistinction to colonnade, which is a range of columns carrying level entablatures. The oldest known in England is probably that of the old refectory in Westminster Abbey, the work of the Confessor (fig. 1). Examples of *attached arcades* may be seen at St John's, Devizes (fig. 2), at Canterbury and Amiens, and at Notre Dame, Paris; of *detached arcades*, at Wells, Lucca, and Pisa; of arcades over piers and arches, at Lincoln; of arcades, the openings of which form seats or canopied stalls (which is very common in chapter-houses), at Lichfield. Arcades are found both inside and outside mediæval buildings. If under the windows inside a

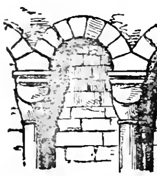

Fig. 1.—Arcade, Westminster Abbey.

Fig. 2.—Arcade, St John's, Devizes.

building, their columns generally rest on a stone seat or bench table. Sometimes the arcades are pierced here and there to form windows. Sometimes the triforium is a series of arcades, as in parts of Canterbury, Exeter, Beverley, St John's, Chester, and many other examples. In detached arcades, a very pleasing effect is often produced by placing the columns, which are attached to the wall, opposite the centre of the opening instead of immediately behind the front column, so as to alternate and enhance the effect of the perspective, as at Wells. The intersections of arcades of interlaced circular arches, as at St John's, Devizes, and at Canterbury, were at one time supposed to have been the origin of the Gothic or pointed arch. Many of the cathedrals abroad have arcaded fronts, as at Pisa. That at Lucca has a range of double arcades, one behind the other, the columns alternating, as may also be seen at Wells and Lincoln. (For examples of arcades, see Parker's *Glossary of Architecture*, and Viollet le Duc's *Dictionnaire*, vol. i.)

ARCADIA, an inland and mountainous country of ancient Greece, bounded on the N. by Achaia, on the W. by Elis, on the S. by Messenia and Laconia, and on the E. by Argolis, and almost shut in from the neighbouring states by a natural rampart. Its most important heights were Cyllene, the birth-place of Hermes, in the north-east, Erymanthus in the north-west, Artemisium and Parthenium in the east, and Mænalus and Lycæus in the south. It was watered by the Alpheus, the largest river of the Peloponnesus, the Helisson, the Ladon, the Erymanthus, and a number of smaller streams which cut their way, in many cases by underground passages, through the limestone rocks. In the east there were several lakes, as those of Orchomenos and Stymphalus; and in the north-east, near Nonacris, was the great waterfall of the Styx, which produced such a deep impression on the ancient Greek mind. Arcadia seems to have been inhabited from the earliest times of Grecian history by the same race of people, which down to the days of Roman dominion continued to be distinguished from the neighbouring states by greater simplicity and inertness of life. Deprived by their position of the quickening influence of commerce, broken up into small and almost independent communities by the physical character of their country, and thus having hardly any proper national existence, the Arcadians acquired a certain awkwardness in dealing with their more vivacious neighbours, who laughed at Arcadian stupidity, while they were pleased with Arcadian hospitality, and almost envied Arcadian repose. Like other mountain-dwellers they were determined defenders of their liberty, and their history is chiefly taken up with united or sporadic conflict against Spartan invasion. About the time of the foundation of Megalopolis (370 B.C.) a certain unity and consequent power were attained, but it was not long ere matters fell back to their former condition. Ultimately the whole country joined the Achæan League, and was afterwards incorporated with the Roman province of Achaia. The most important towns in Arcadia were Tegea, Stymphalus, Cleitor, Pallantium, Pheneus, Caryæ, Nonacris, Methydrium, Heræa, Mantinea, Lycosura, according to Pausanias, the most ancient town in Greece, and Megalopolis, one of the most recent. The Greek and Roman poets celebrated the simplicity of Arcadian life and character, not without a certain touch of satire; but by moderns, such as Sannazar and Sydney, the country and its inhabitants have been idealised and elevated into a type of pure pastoral happiness.

ARCESILAUS, a Greek philosopher, and founder of the New or Middle Academy, was born at Pitane in Æolia, about 316 B.C. He received careful training in his youth from the mathematician Autolycus, and then proceeded to Athens, where for some time he studied under Theophrastus. He was gained over to the Academy by Crantor, with whom he continued to live on terms of the closest intimacy. After the death of Crantor, Arcesilaus continued to study under Polemo and then under Crates, whom he succeeded as leader of the school. There is a little doubt as to the philosopher's mode of life. According to some he lived in extravagant, even profligate style, and Diogenes Laertius tells us that he died in his 75th year of excessive drinking. But the testimony of others, *e.g.*, Cleanthes, seems to show that he practised extreme moderation; and some of his practical precepts tend to confirm this view. He was much beloved and respected by the Athenians, and is celebrated for his acuteness, eloquence, and learning. His philosophical opinions can only be gathered from scattered notices in Cicero, Sextus, and others. He advocated the Socratic or colloquial method of discussion, although he depreciated dialectic proper, and seems to have carried out thoroughly the sceptical element in the Platonic school. His theory of knowledge was developed in direct antagonism to that of the Stoics. He especially opposed their favourite doctrine, that the criterion of truth was to be found in the irresistible or irresistibly convincing impression, which served as a mean between science and opinion, and was common to the wise man and the foolish. Arcesilaus denied that such a mean was possible, and showed further, that as conviction implied approval or judgment, it could not apply to impressions but only to thoughts. Moreover, the mere force of conviction could not be a test of truth, since a false conception might be quite as irresistible as a true one. Arcesilaus brought forward no new arguments against knowledge in general; he appears to have thought that by overthrowing the theory of knowledge which rests on the truth of the senses, he had destroyed all possibility of rational conviction. The final result of his speculation was accordingly, that he could not know anything, not even his own ignorance. It was the part of a wise man to despair of certainty. To the ordinary argument against scepticism, that it destroys the power of acting, Arcesilaus replied by pointing out that impressions or ideas affect the will and produce actions, whether they are true or not. Men can act upon their ideas with or without a conviction of their truth. In practical matters probability is a sufficient guide. We have no certain information as to how this doctrine was applied to the questions of morals. (See Brodeisen, *De Arcesila philosopho*, 1821; Geffers, *De Arcesila*, 1842; Zeller, *Philosophie d. Griechen*, iii. 1, 448, *sq*.

ARCH

ARCH, in building, a portion of mason-work disposed in the form of an arc or bow, and designed to carry the building over an open space. The simplest and oldest expedient for supporting a structure over a door-way is to use a single stone or lintel of sufficient length. On account of the difficulty of procuring stones of great size, this expedient can only be used for moderate apertures; nor can it be applied when there is to be a heavy superstructure, because the weight resting on the lintel would cause a compression of the upper, and a distension of the under side. Now, no kind of stone can bear any considerable distending strain, and thus stone-lintels are liable to fracture. The ancient Greek temples afford instances of the use of horizontal lintels of considerable size, but these architraves carry only the cornice of the building. The employment of a colonnade with flat architraves to support an upper story is contrary to sound principles, and, even in the case of ordinary houses, we see that the builder has been fain to relieve the pressure on the lintel by means of a concealed arch. In stone-work we must depend on compression alone.

When a lintel had been accidentally broken in two, we may suppose that the masons had set the ends of the halves upon the door-posts, and brought the broken ends

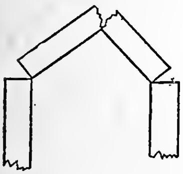

Fig. 1.

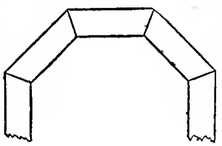

Fig. 2.

together. In this way there would be formed a support for the upper building much stronger than was the stone when entire; only there is a tendency to thrust the door-posts asunder, and means must be taken to resist this out-thrust. The transition from this arrangement to that of three or more wedge-shaped stones fitted together was easy, and thus the gradual development of the arch resulted.

So long as such structures are of small dimensions no great nicety is required in the adaptation of the parts, because the friction of the surfaces and the cohesion of the mortar are sufficient to compensate for any impropriety of arrangement. But when we proceed to construct arches of large span we are forced to consider carefully the nature and intensity of the various strains in order that provision may be made for resisting them.

Until the laws of the equilibrium of pressures were discovered, it was not possible to investigate these strains, and thus our knowledge of the principles of bridge-building is of very recent date; nor even yet can it be said to be perfected. The investigation is one of great difficulty, and mathematicians have sought to render it easier by introducing certain pre-supposed conditions; thus, in treatises on the theory of the arch, the structure is regarded as consisting of a course of arch-stones resting on abutments, and carrying a load which is supposed to press only downwards upon the arch-stones. Also cohesion and friction are put out of view, in other words, the investigation is conducted as if the stones could slide freely upon each other. Now, if the line of pressure of one stone against another cross their mutual surface perpendicularly, there is no tendency to slide; and if this condition be adhered to throughout the whole structure, there must result complete stability, since the whole of the friction and the whole consistency of the cement contribute thereto. But if, in any case, the line of pressure should cross the mutual surface obliquely, the tendency to slide thereby occasioned must be resisted by the cohesion, and so the firmness of the structure would be impaired. Hence an investigation, conducted on the supposition of the non-existence of cohesion, must necessarily lead us to the best possible construction. But we can hardly say as much in favour of the hypothesis that the load presses only downwards upon the arch-stones. In order to place such a supposition in accordance with the facts of the case, we should have to dress the inner ends of the arch-stones with horizontal facets for the purpose of receiving and transmitting the downward pressure. But if, as is usually the case, the inner surfaces be oblique, they cannot transmit a vertical pressure unless in virtue of cohesion, and then this hypothesis of only downward pressure on the arch-stones is not in accordance with the fundamental principle of stability. In a thorough investigation this hypothesis must be set aside, and the oblique pressure on the inner ends of the arch-stones must be taken into account. Since the depth of the arch-stones is small in comparison with the whole dimensions of the structure, and since the line of the pressure transmitted from one to another of them must always be within that depth, it is admissible to suppose, for the purpose of analysing the strains, that the arch-stones form an exceedingly thin course, and that their joints are everywhere normal to the curve of the arch. Eventually, however, the depth of the arch-stones must be carefully considered.

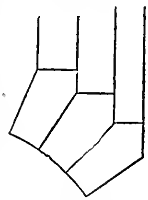

Fig. 3.

We may best obtain a clear view of the whole subject by first assuming that the load presses only downwards on the arch-stones, or that the inner ends of these are cut with horizontal facets.

Let Q′P′APQ (fig. 4) represent a portion of such an arch

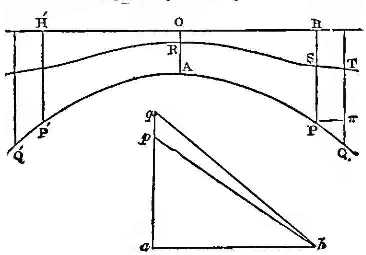

Fig. 4.

placed equally on the two sides of the crown A, then the whole weight of the structure included between the two vertical lines P′H′ and PH must be supported at P′ and P, so that the downward pressure at the point P must be the weight of the building imposed over AP. This pressure downwards is accompanied by a tendency to separate the supporting points P′ and P. Now, as this tendency is horizontal its intensity cannot be changed by the load acting only downwards, and must remain the same throughout the structure, wherefore the actual pressure at P must be found by combining this fixed horizontal thrust with the downward pressure equal to the weight of the bridge from A to P. If, then, we draw *ah* horizontally to represent this constant thrust, and *ap* upwards to represent the weight of this portion of the arch, the line *ph* must, according to the law of the composition of pressures, indicate both in direction and in intensity the actual strain at the point P. This pressure must be perpendicular to the joint of the stones, and must therefore be parallel to the straight line drawn to touch the curve at P.

Hence, if the form of the inside of the arch, or the *intrados* as it is called, be prescribed, we can easily discover the law of the pressures at its various parts; thus, to find the strain at the point Q, we have only there to apply a tangent to the curve and to draw *hq* parallel thereto; *hq* represents the oblique strain at Q; *aq* represents the whole weight from the crown A to Q, and therefore *pq* is proportional to the weight imposed upon the position PQ of the arc.

Using the language of trigonometry, the horizontal thrust is to the oblique strain at any part of the curve as radius is to the secant of the angle of inclination to the horizon; also the same horizontal thrust is to the weight of the superstructure as radius is to the tangent of the same inclination. And thus, if the intrados be a known curve, such as a circle, an ellipse, or a parabola, we are able without much trouble to compute, on this hypothesis, the load to be placed over each part.

If we use the method of rectangular co-ordinates placing x along OH and z vertically downwards, so that $P\pi$ may be the increment of x, πQ that of z, the tangent of the inclination at P is $\frac{\delta z}{\delta x}$, and therefore if h stand for the horizontal strain and w for the weight of the arch, we have—

$$w = h\frac{\delta z}{\delta x},$$

while the oblique strain is $h\sqrt{\left(\frac{\delta x^2+\delta z^2}{\delta x^2}\right)}$. Also the change of weight from P to a proximate point Q is $\delta w = h\delta\left(\frac{\delta z}{\delta x}\right)$.

Let RST be the outline which the mason-work would have if placed compactly over the arch-stones, in which case RST is called the *extrados*, then the weight supported at P is proportional to the surface ARSP, and the increment of the weight is proportional to PSTQ, hence if the weights and strains be measured in square units of the vertical section of the structure, and if y be put for PS, the thickness of the mason-work, we have—

$$\delta w = y\delta x, \text{ whence } y = h\frac{\delta^2 z}{\delta x^2}$$

When the curve APQ is given, the relations of z and of its differentials to x are known, and thus the configuration of the extrados can be traced, and we are able to arrange the load so as to keep all the strains in equilibrium.

But when the form of the extrados is prescribed and that of the intrados is to be discovered, we encounter very great difficulties. Seeing that our hypothesis is not admissible in practice, it is hardly worth while to engage in this inquiry; it may suffice to take a single, and that the most interesting case.

If the whole space between the arch-stones and the roadway be filled up, the extrados becomes a straight line, and when this is horizontal we have $y = z$, so that the form of the arch must be such as to satisfy the condition—

$$z = h\frac{\delta^2 z}{\delta x^2},$$

that is to say, z must be a function of x such as to be proportional to its own second derivative or *differential coefficient*. Now this character is distinctive of the catenarian functions, and therefore ultimately

$$z = A\left\{e^{\frac{x}{\sqrt{h}}} + e^{-\frac{x}{\sqrt{h}}}\right\}$$

where A is AO, the thickness at the crown of the arch, and e the basis of the Napierian system of logarithms. In this case, since $\delta w = z\delta x$,—

$$w = A\sqrt{h}\left\{e^{\frac{x}{h}} - e^{-\frac{x}{h}}\right\},$$

so that the form of the arch and also its weight may readily be computed by help of a table of catenarian functions.

Let us now consider the case when the ends of the arch-stones are dressed continuously, while the imposed load is formed of stones having vertical faces. The weight of the column PSTQ resting on the oblique face PQ is prevented from sliding by a resistance on the vertical surface QT, which resistance goes to partly oppose the horizontal strain transmitted by the preceding arch-stone; and thus the out-thrust of the arch, instead of being entirely resisted by the ultimate abutment, is spread over the whole depth of the structure. In this case the horizontal thrust against QT is to the weight of the column as $Q\pi$, the increment of z, is to $P\pi$, the increment of x; wherefore, putting H for the horizontal thrust at the crown of the arch, and h for that part of it which comes down to P, the decrement of h from P to Q is proportional to the rectangle under PS and $Q\pi$, that is to say,

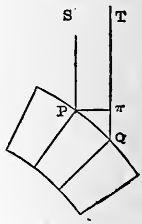

Fig. 5.

$$\delta h = y\delta z.$$

Now, the whole decrement from the crown downwards is the sum or integral of all such partial decrements, and therefore the horizontal thrust transmitted to P is expressed by the symbol—

$$h = H - \int y\delta z,$$

while the whole weight supported at P is the analogous integral

$$w = \int y\delta x.$$

But the resultant of these two pressures must be perpendicular to the joint of the arch-stones, or parallel to the line of the curve; wherefore ultimately we obtain, as the condition of equilibrium in such a structure, the equation—

$$\delta z(H - \int y\delta z) = \delta x\int y\delta x.$$

Since the vertical pressure at P is w, while the horizontal strain is h, the intensity of the oblique strain at P must be $\sqrt{\{w^2+h^2\}}$. Now, in passing to the proximate point Q, w becomes $w+\delta w$, while h is reduced to $h - \delta w\frac{\delta x}{\delta z}$, so that the oblique strain at Q must be—

$$\sqrt{\left\{(w+\delta w)^2 + \left(h - \delta w\frac{\delta x}{\delta z}\right)^2\right\}},$$

or, neglecting the second power of the infinitesimally small increment δw, $\sqrt{\left\{w^2+p^2+2w\delta w - 2h\delta w\frac{\delta z}{\delta x}\right\}}$, but

$w = h\frac{\delta z}{\delta x}$, wherefore the strain at Q is $\sqrt{(w^2+h^2)}$, or exactly the same as that at P. This result might have been obtained from the consideration that the thrust upon the surface PQ is perpendicular to the oblique strain, and can tend neither to augment nor to diminish it. Hence, as a characteristic of this arrangement, we have the law that the tension across the joints of the arch-stones is the same all along, and therefore is equal to H, the horizontal tension at the crown of the arch.

From this it at once follows that if r be the radius of curvature at the point P, y being the vertical thickness of the mason-work there, $H = ry$, so that if R be the radius of curvature at the crown of the arch, and A the thickness there, the horizontal thrust there, or the strain transmitted along the arch-stones, is $H = RAH$, being measured in square units of surface; hence also $A : y :: r : R$, or the thickness at any place, is inversely proportional to the radius of curvature there.

When the form of the intrados is given, its curvature at any point is known, and from that the thickness of the stone-work and the shape of the extrados can be found. The most useful case of the converse problem is, again, that in which the extrados is a horizontal straight line.

Let OH, figure 6, be the horizontal extrados, and A the crown of the arch; make also AB such that its square may represent the horizontal thrust there; then, having joined OB and drawn BC perpendicular to it, and meeting the continuation of OA in C, C is the centre of curvature for the crown of the arch. Or, if the radius of curvature and the thickness of the arch at the crown be prescribed, we may obtain the horizontal thrust by describing on CO a semicircle, cutting a horizontal line through A in the point B, then the horizontal thrust is equal to the weight of the quantity of the stone-work which would fill up the square on AB. The conditions of the problem require that the curve APQ be so shaped as that the radius of curvature at any point P shall be inversely proportional to the ordinate HP.

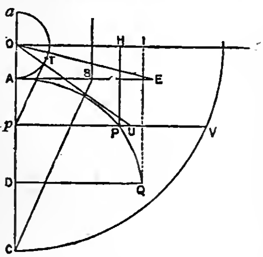

Fig. 6.

Resuming the general equation of condition—

$$\delta z(H - \int y\delta z) = \delta x \int y \delta x\,,$$

and observing that in this case $y = z$, we have—

$$\delta z(H - \int z\delta z) = \delta x \int z \delta x$$

Now the integral $\int z\delta z$ is $\frac{1}{2}z^2$, but as it must be reckoned only from A where $z = A$, the equation becomes

$$\delta z(H + \tfrac{1}{2}A^2 - \tfrac{1}{2}z^2) = \delta x \int z \delta x$$

The coefficient of δz becomes less when z increases, and when $\frac{1}{2}z^2 = H^2 + \frac{1}{2}A^2$, this coefficient becomes zero, at which time δx also becomes zero in proportion to δz; that is to say, the direction of the curve becomes vertical. Wherefore, if we make $OD = D$ such that $D^2 = A^2 + 2H^2$, we shall obtain that depth at which the curve is upright, or at which the horizontal ordinate DQ is the greatest, and then the equation takes the form—

$$\delta z(D^2 - z^2) = 2\delta x \int z \delta x\,,$$

by help of which we should be able to find x in terms of z. The computation, however, is attended with considerable difficulty, and therefore it may be convenient to attempt a graphical solution. Since, for any vertical ordinate $HP (= z)$, the horizontal thrust is $\frac{1}{2}(D^2 - z^2)$, while the oblique strain is $\frac{1}{2}(D^2 - A^2)$, the obliquity of the curve at P has for its cosine the value $\frac{D^2-z^2}{D^2-A^2}$, wherefore the angle at which the curve crosses the horizontal line pP is known. Let then a multitude of such lines be drawn in the space between BA and DQ, and let the narrow spaces thus marked be crossed in succession from A downwards by lines at the proper inclination, and we shall obtain a representation of the curve, which will be nearer to the truth as the intervals are more numerous. The beginning of the curve at A may be made a short arc of a circle described from the centre C.

Since the minute differentials thus obtained are proportional to the sides of a triangle whose hypotenuse is $D^2 - A^2$, and one of whose sides is $D^2 - z^2$, we must have—

$$\delta x = \frac{D^2 - z^2}{\sqrt{\{(D^2-A^2)^2 - (D^2-z^2)^2\}}}\delta z\,,$$

and the integration of this would give the value of x. If we put ϕ for the inclination of the curve at any point P,

$$D^2 - z^2 = (D^2 - A^2)\cos\phi,$$

$$\therefore z = \{D^2 - (D^2 - A^2)\cos\phi\}^{\frac{1}{2}}$$

and taking the differential,

$$\delta z = \tfrac{1}{2}(D^2 = A^2)\sin\phi\{D^2 - (D^2 - A^2)\cos\phi\}^{\frac{1}{2}}\delta\phi,$$

$$\therefore \delta x = \frac{H.\cos\phi.\delta\phi}{\sqrt{\{D^2 - 2H\cos\phi\}}}\,,$$

where 2H is put for its equivalent $D^2 - A^2$. The integral of this expression may be obtained by developing the radical in terms arranged according to the powers of $\cos\phi$, and then integrating each term separately. The result is a series of terms proceeding by the powers of $\cos\phi$, the coefficient of each power being itself an interminate series; and the rate of convergence is so slow as to make the labour of the calculations very great. Such expressions belong to the class of *elliptic functions*, for which peculiar methods have been devised. Fortunately the actual calculation is not required in the practice of bridge-building, and therefore we shall only refer the reader to the above-named subject.

If the horizontal thrust and the thickness at the crown of the arch be prescribed, the radius of curvature there must be the same whichever of the two hypotheses be adopted; now, if we sweep an arch from the centre C with the radius CA, the catenarian curve lies outside of it, while the curve which we have just been considering lies inside. Each of these is compatible with sound principles: the one if the inner ends of the arch-stones be dressed with horizontal facets, the other if the ends be dressed to a continuous curve; wherefore, between these two limits we may have a vast variety of forms, each of which may be made consistent with the laws of equilibrium by merely dressing the inner ends of the arch-stones at the appropriate angles. Hence an entirely new field of inquiry, in which we may find the complete solution of the general problem:—

"The intrados and extrados of an arch being both prescribed, to arrange the parts consistently with the laws of equilibrium."

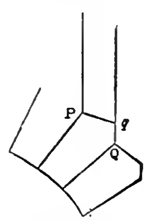

Fig. 7.

Let PQ represent the inner end of one of the arch-stones, the part Qq being vertical, and Pq being sloped at some angle which is to be found; put t for the tangent of the inclination of the joint P to the vertical, θ for that of Pq to the horizontal line, then the horizontal strain at P is $\frac{w}{t}$, while the corresponding strain at Q is $\frac{w+\delta w}{t+\delta t}$, and if Pq were horizontal these would be alike; but the obliquity of Pq causes the load δw which is placed on it to generate a horizontal pressure $\theta\delta w$, wherefore—

$$\frac{w}{t}-\frac{w+\delta w}{t+\delta t}=\theta\delta w, \text{ whence}$$

$$\theta=\frac{w}{t^2}\frac{\delta t}{\delta w}-\frac{1}{t} \text{ or } \theta t=\frac{w}{\delta w}\frac{\delta t}{t}-1$$

Now, when the forms of the intrados and extrados are both given, the values of w, t, δw, δt, are thence deducible, so that the value of θ may always be computed by help of differentiations only; excepting, indeed, that integrations may be needed for determining the value of w, which is the area included between the two curves.

In this very simple investigation we have the complete solution of the principal problem in bridge-building. The data needed for determining the shape of the inner end of the arch-stone are already in the hands of the architect, who must know, from his plans, the weight of each part and the inclination of each joint; so that, with a very small addition to the labour of his calculations, he is enabled to put the structure completely in equilibrium, even on the supposition of there being no cohesion and no friction; that is to say, he is enabled to obtain the greatest stability of which a structure having the prescribed outlines is susceptible. Even although he may not care to have the stones actually cut to the computed shape, and may regard their usual roughness and the cement as enough, he may judge, by help of the above formula, of the practicability of his design; for if at any place the value of $\theta\delta t$ come out with the wrong sign, that is, if $w.\delta t$ be less than $t.\delta w$, the building is unstable, whereas if $w.\delta t$ be greater than $t.\delta w$ everywhere, the design, as far as these details go, is a safe one.

In every possible arrangement of the details, the horizontal thrust at the crown of the arch is transmitted to and resisted by the ultimate abutments. The only effect, in this respect, of varieties in the form of construction is to vary the manner of the distribution of that strain among the horizontal courses. Hence one great and essential element of security,—the first thing, indeed, to be seen to,—is that the ground at the ends of the proposed bridge be able to resist this out-thrust. Another, and not less important one is, that the arch-stones be able to withstand the strains upon them. In this respect much depends on the workmanship; it is all important that the stones touch throughout their whole surfaces: if these surfaces be uneven the stones must necessarily be subjected to transverse strains, and so be liable to fracture. The practice, too common among house-masons, of cheaply obtaining an external appearance of exactitude, by confining their attention to a chisel-breadth around the outside, is not permissible here, nor should any reliance be placed on the layer of mortar for making up the inequalities.

The limit to the span of an arch depends primarily on the quality of the material of the arch-stones. At the crown of the arch the horizontal thrust is the weight of as much of the masonry as fills a rectangle whose length is equal to R, the radius of curvature, and whose breadth is A, the effective thickness there; now this strain has to be borne by the arch-stones, whose depth we shall denote by d, and therefore these stones must be subjected, as it were, to the direct pressure of a vertical column whose height is $\frac{RA}{d}$. This column must be much shorter than that which the stone is actually able to bear.

The ability of a substance to resist a crushing pressure is generally measured by the length of the column which it is able to support, without reference to the horizontal section; but it may be questioned whether this mode of estimation be a sound one, for it does seem natural to suppose that a block three inches square should bear a greater load than nine separate blocks each one inch square, seeing that the centre block in the entire stone is protected on all sides; and thus it is possible that we under-estimate the greatest practicable span of a stone arch. This difficult subject belongs to the doctrine of "Strength of Materials."

Arch, Skewed.—In the earlier days of bridge-building the road was led so as to cross the river or ravine perpendicularly, but in modern engineering we cannot always afford to make the detour necessary for this purpose, and must have recourse to the *skewed* or *oblique* arch, having its plan rhomboidal, not rectangular.

If AB, CD, figure 8, represent the roadway, and EF

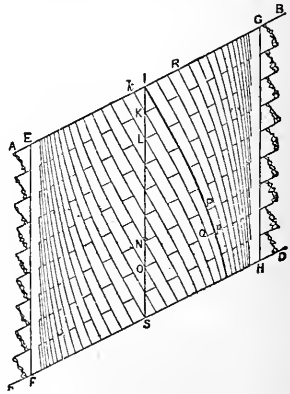

Fig. 8.

GH, the boundaries of the abutment walls placed obliquely, we easily perceive that the thrust cannot be perpendicular to the abutments, for then it would go out on the side walls which have no means of resistance; the thrust can only be resisted in the direction of the road. Hence if the structure be divided into a multitude of slices by vertical planes parallel to the parapet, the strains belonging to each slice must be resisted within that slice, and each should form an arch capable of standing by itself. The abutment, therefore, cannot have a continuous surface as in the common or right arch, but must be cut in steps to resist the oblique pressure; wherefore also the ultimate foundation stones must present surfaces perpendicular to the road.

Attending for the moment to one only of these divisions, say to a thin slice contiguous to the side wall EG, let us study the manner in which the arch-stones in it must be shaped. At the crown I the pressure is horizontal in the plane EIG, and therefore the joint of the stones there must be perpendicular to AB, and so also must be its projection on the horizontal plane.

Proceeding along the line of the curve to the point R, we observe that the pressure there must be in the direction of a tangent to the curve, wherefore the surface of a joint at R must be perpendicular to that tangent, and the exposed face of the stone must be right-angled. Now, the projection upon a horizontal surface of a right angle placed obliquely is not necessarily right; in this case it cannot be right, and therefore the course of a line of joints represented in plan must bend away from being perpendicular to the side wall towards being parallel to the line of the abutment. Thus a continuous course of joints beginning at I must be shown in plan by some curved line such as IPp.

In many of the skewed bridges actually built, the outline of the arch is divided into equal parts, as seen on the ends of the vault; the curved joint-lines IPp thus become portions of screws drawn on an oblique cylinder, and, although the arch-stone at the crown be rectangular, those on the slope cease to be so. The bearing surface is thus inclined to the direction of the pressure, and the tendency is to thrust out the arch-stones at the acute corners F and G. The fault is exactly the same as if, in ordinary building, the mason were to bed the stones off the level. The consequence is that skewed stone-bridges have not given satisfaction, the fault being attributed to the principle of the skew, whereas it should have been assigned to the unskilfulness of the design.

Let figure 9 be an elevation projected on a vertical plane parallel to AB, EIG, FSH, being the outlines of the ends

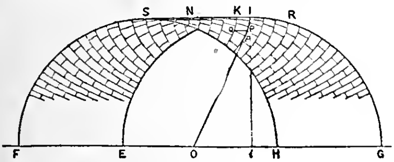

Fig. 9.

of the arch, and the sections taken at equal intervals along the crown line being also shown; then, since the projection of a right angle upon a plane parallel to one of its sides is always right, the joint at R, as seen on this elevation, must be perpendicular to the curve at R, and thus the curve IPp, representing one of the joint-courses, must cross each of the vertical sections perpendicularly. In this way each of the four-sided curvilinear spaces into which this elevation is divided must be right-angled at its four corners. This law is general, and enables us to determine the details of any proposed oblique arch.

If we draw, as in figure 9, the end elevation of the vault as intersected by numerous parallel planes, and lead a curved line crossing all these intersections perpendicularly, we obtain the end elevation of one of the joint-lines, and are able from it to prepare any other of its projections. The form and character of this end elevation IPp depends entirely on the nature of the curve EIG, but is the same whatever may be the angle of the skew. In order to examine its general character, let us take in the crown line two closely contiguous points I, K, and from these lead the joint-lines IP, KQ, of equal length, then the straight line PQ is equal and parallel to IK, on any of the projections.

If in the end elevation, figure 9, we continue the joint IP to meet the vertical section OQ in p, we may regard PQp as a small rectilineal triangle, right angled at p, while PQp is the inclination to the horizon. Now, $PQ : Qp :: R : \cos PQp$, while PQ is equal to KI, the breadth of the arch-stone at the crown, wherefore the breadth of the course at the crown is to the breadth of the same course at any other place as radius is to the cosine of the inclination there. Hence it follows, as is shown in the end elevation, figure 10, that the arch-stones gradually diminish in breadth from the crown downwards, being halved in breadth at an inclination of 60°. At a greater inclination they become

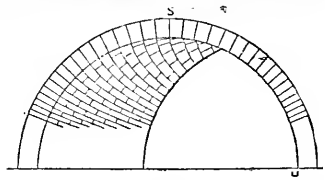

Fig. 10.

still narrower, and an infinity of them would be needed to reach the abutment of a semicircular or semi-elliptic arch, because the cosine of the inclination there is zero. In no properly-built skewed bridge can the arch-stones show equal divisions; and it is impossible to continue the arch to the complete half circle or half ellipse.

Passing from the end elevation, figure 9, to the plan, figure 8, we observe that Qp on the plan is less than the actual Qp of the elevation in the ratio of the cosine of the inclination to radius, and, therefore, on the plan, the breadth at the crown is to the apparent breadth of the course at any other place as the square of the radius is to the square of the cosine of the inclination there; so that, at the inclination of 60° the apparent breadth will be quarter of that at the crown.

Again, in figure 11, which is the side elevation of the vault, or its projection on a vertical plane perpendicular to the road, the apparent distance Qp is to the actual distance Qp of figure 9 as the sine of the inclination is to radius, wherefore, the apparent breadth Qp on this projection is proportional to

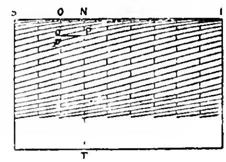

Fig. 11.

the product of the sine by the cosine of the inclination, that is, to half the sine of twice the inclination. The width on this projection is therefore greatest at an inclination of 45°, being there just one-half of the actual breadth at the crown of the arch

This reasoning is founded on the supposition that the distance IK is excessively small, and the resulting conclusions are strictly true only of an infinitely narrow course of arch-stones; they are, indeed, *differential equations* which must be *integrated* in order to be applied to actual practice. Thus we have seen that the curved line IP, figure 9, crosses the section NP perpendicularly at P, but then it does not continue in this direction for any perceptible distance. The draughtsman may attempt to trace it by making the sections very numerous, and by drawing perpendiculars across the successive intervals; but however numerous he may make these sections, he can thus only effect an approximation to the true curve. We must *integrate*, that is, we must obtain the aggregate of an infinite number of infinitely small portions in order to reach an absolutely true result.

These conclusions hold good whatever may be the outline of the arch. The most common, and therefore the most interesting case, is when the longitudinal section is circular, the cross section taken perpendicularly to the abutment being then an ellipse with its shorter diameter placed horizontally, the vault being an oblique cylinder. Figure 9 is actually drawn for the circular arch. If then O be the centre of the circular arc NP, the curve IP must at P tend towards O, so that the draughtsman, while making the step across one of the intervals, has only to keep his straight edge up to the corresponding place of the centre. If we place the paper horizontally, fix a small heavy round body at P to the end of a thread OP, and then draw the end O of that string along the straight line HEF, P would always move towards the then position of the point O, and would trace out the curve of which we are in search. The projection, then, of the joint of an oblique circular arch upon a vertical plane parallel to the road, is always the curve known by the name of the *Tractory.* All tractories have the same shape, the size merely is regulated by the length of the thread OP, that is, by the radius of curvature of the circular arch. Hence, if the delineation of it have been accurately made in one case, the curve for another case may be obtained by mere enlargement or reduction; or, still better, in all cases it may be traced by help of a table of co-ordinates, such as that subjoined, which shows the dimensions of the tractory as represented in figure 12, in decimal parts of the radius of curvature of

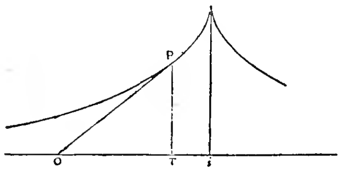

Fig. 12.

the arch. The computations have been made for equal motions of the point O, corresponding, therefore, to equal distances measured along the crown-line of the arch. The headings of the columns sufficiently explain their contents. By help of these the form of the tractory may easily be obtained, and with a piece of veneer or of thin metal cut to this shape, the architect may obtain all the details of the intended structure, first working out the said elevation, figure 9, and transferring the several points therefrom to the other projections.

If we put s for the angle of the skew, v for the distance IN measured along the crown of the vault, and i for the inclination at the point P, r being the radius of the arch, the distance IN or iO of figure 10 is clearly $v \sin s$, and as the result of the integration, we obtain—

$$\frac{v \sin s}{r} = \text{Nap. log tan } (45° + \tfrac{1}{2}i),$$

by help of which equation we can readily determine i when v is known, or v when i is given. The table of Napierian logarithmic tangents being very scarce, it is convenient to convert these into denary or common logarithms. Putting, as is usual, M for the modulus of denary logarithms, that is, for ·43429 44819, the above equation becomes—

$$\frac{\mathrm{M}}{r} \, . \, v \, . \sin s = \log \tan (45° + \tfrac{1}{2}i),$$

from which it is quite easy to tabulate the values of i corresponding to equidifferent values of v, because the constant factor—

$$\frac{\mathrm{M} \, . \sin s}{r}$$

has to be only once computed; i, that is, the number of degrees in the arc NP being thus computed for each of the successive sections of the vault, we have only to divide a tape-line so as to show degrees and minutes of the actual circle in order to be able at once to mark the course of the joints upon the centering of the arch; or better still, instead of the degrees, we may write upon the tape the successive values of NP, and then the commonest workman will be able to lay off the lines.

The only other kind of skewed arch likely to possess any interest is the elliptic. In right arches the semi-ellipse is sometimes used on account of the grace of its form, but this reason for its adoption disappears in the case of the skew, because then we can only use a portion of the semi-ellipse. The end elevation of a joint in an elliptic skewed arch is a modified form of the tractory, and the general features of the arrangement are analogous to those of the circular arch.

The arch-stone of a common bridge is wedge-shaped, having two flat faces AacC, BbdD, inclined to suit the breadth of the course, but in the skewed bridge the corresponding faces are twisted, Cc not being parallel to Aa, and thus the dressing of them requires both skill and care. The dimensions of the stone and the inclinations of its four

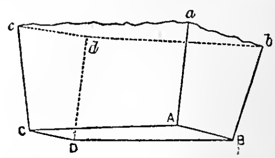

Fig. 13.

edges may easily be computed when its intended position is known, and thus the degree of twist on each of its faces may be ascertained, and the lines may then be marked off on the ends of the stone.

The theory of the skewed arch was given for the first time in the *Transactions of the Royal Scottish Society of Arts* for 1838; from which it was copied into the *Civil Engineer and Architect's Journal* for July 1840, which see. (For the history and various forms of the arch see ARCHITECTURE.) (E. S.)

ARCHÆOLOGY

ARCHÆOLOGY, from ἀρχαῖος, ancient, and λόγος, a description. The term *Archæology*, like that of *Antiquities*, has been employed, until a very recent period, in a sense so restricted and arbitrary as strikingly to contrast with the latitude admissible according to the original derivation of the word. Literally it signifies the study of antiquity or ancient things; but its precise significance has been determined from time to time by the range of study and research most in favour. To some extent it has always been recognised as embracing whatever pertained to the early history of any nation, but in its details it was applied almost exclusively to the study of Greek and Roman art, or of classical antiquities generally. The progress of geology, and the application of sound principles of induction to the study of primitive antiquities, have wrought a great revolution, and few studies now rival archæology in comprehensive interest.

In looking at the succession of strata of the earth's crust it was assumed till recently that the student of man and his remains is limited to the latest superficial formation of post-tertiary strata. To the palæontologist was assigned all ancient animal life of the fossiliferous strata, while the archæologist treated of man and his works as things essentially distinct. The diverse functions of the two sciences are still clearly recognised; but the archæologist is no longer supposed to be excluded either from quaternary or tertiary strata in his search not only for the remains of human art, but for the osteological evidences of man's presence contemporaneous with the fauna of such geological periods. One class of archæologists, accordingly, confidently anticipate the recovery not only of works of art, but of the fossil remains of man himself, in the pliocene, or even the miocene strata. So far, however, as any reliable evidence can guide opinion, it scarcely admits of question that neither has hitherto been found in older deposits than the later tertiary, or quaternary.

The actual remains of man, the specific form of his osseous structure, and above all of his skull, now receive the minutest attention; and the department of anthropology to which such investigations are specially assigned has latterly acquired a fresh interest from the inquiries suggested by novel theories as to the possible evolution of man from lower animal organisations. Nevertheless, the researches of the palæontologist and of the archæologist are based on essentially distinct evidence. The life of geological periods is investigated by means of the fossil bones and teeth which alone survive. Or if to these have to be added such illustrations of habits, food, and structure as are furnished by means of footprints, coprolites, and the like subsidiary evidence, still all are traceable, directly or indirectly, to the living organism. Man, on the contrary, in times altogether preceding history, is chiefly studied by means of his works. Archæology thus forms the intermediate link between geology and history, though the reaction, at the revival of learning in the 16th century, which tended for a time to subordinate arts and science alike to classical authority, reduced it within greatly narrower limits. Nevertheless, the fitness of the term for the most comprehensive definition in relation to all which pertains to the past could not be entirely overlooked, and it is even employed repeatedly by Dr Prichard as nearly synonymous with palæontology. In this, however, he has not been followed, and the name is now universally adopted to designate the science which deduces the history of man from the relics of the past. So comprehensive a subject necessarily admits of great subdivision. The most important general division will be treated of separately in the article on CLASSICAL ARCHÆOLOGY (p. 343, *sqq.*), while interesting branches of the study will be reviewed under the heads of Egyptian, Etruscan, Assyrian, Mexican, and Indian antiquities. Numismatics, pottery, heraldry, hieroglyphics, palæography, and other subdivisions in like manner deal with important details, and help to illustrate the comprehensiveness of the subject.

The innate cravings of the human mind for an insight into the future have shaped themselves into many forms of divination and astrology. But this desire is not more universal than that which prompts man to aim at a recovery of the secrets of the past. The question *Whence?* even more than that of *Whither?* is found to give shape to the mythic legends of the rude barbarian, and to constitute an important element in the poetry and mythology of every nation's oral and written history. With the progress of society such indices of the past are subjected anew to critical analyses; and we accordingly find abundant traces of an archæological spirit in the literature of every civilised nation. The influence of the same craving for a mastery of the past is seen adapting itself to the spirit of the age at every epoch of great progress. The revival of art and letters in the 14th and 15th centuries was signalised by a renewed appreciation of Greek and Roman models; and while the progress of opinion in the 16th century was accompanied by an abandonment of mediæval for classic art, the tendency of Europe in our own day, amid many elements of progress, has been singularly consentaneous in the return not merely to mediæval art, but to mediæval modes and standards of thought, and in the attempt to attain to higher excellence than has been yet achieved by a more perfect development of the ideal of the middle ages.

The alliance of archæology with geology, and the direction of geological research to the evidences of the antiquity of man, have largely contributed to its expansion, until in its comprehensive unity it embraces the entire range of human progress from the infantile stage of primeval arts to the earliest periods of written records. It has thus been developed into a systematic science, by which the intelligent investigator is enabled to pursue his researches with the aid of evidence older than all written chronicles, and to recover chapters of national infancy and youth heretofore deemed beyond recall. The geologist, with no aid from written records, follows out his inquiries through successive periods of the earth's history, and reveals the changes it has undergone, and the character of the living beings which animated epochs of the globe ages before man was called into being. Beginning with the traces of life in the primary fossiliferous strata, he passes on from system to system, disclosing a vast succession of long extinct life, until in the latest diluvial formations he points to the remains of animals identical with existing species, and even to traces of human art—the evidence of the close of geological and the beginning of archæological periods. Here archæological science ought to be ready to take up the narrative, and with a more comprehensive minuteness of detail and greater certainty as to the conclusions arrived at. Such, however, until very recently, has not been the case. The geologist himself long confused the records of the transitional period by his mistaken reference of all diluvial traces to the Noachian deluge; and when, pausing, as he thus believed, at the dawn of the historic period, he turned to the archæologist for the subsequent chapters of the history of life on our globe, it was only to receive a record of Roman traces at best but meagrely supplementing the minuter details of the historian. Nearly the same was the case with all historic antiquity, with the single exception of the wonderful monuments of Egypt, which preserve to us the records of a civilisation in which we can recognise the origin of arts, letters, and all else to which the culture of the oldest historical nations may be traced.

Nevertheless, the evidences of the primitive arts, and the traces of a native civilisation originating among the prehistoric races of Europe, had been long familiar to the antiquary, though he failed to form any intelligent conception of their significance as historical records. Their interpretation on an intelligent and systematic principle is mainly due to the archæologists and ethnologists of Denmark and Sweden, who from their very geographical position were happily freed from the confusing element of classical prejudices, and were compelled to seek in other than Roman sources an origin for the abundant traces of metallurgic art. Zealous British coadjutors speedily caught the hint, and freed themselves from the trammels which had so long narrowed their aim; the remains of primitive art were referred to true sources, or at least arranged under an intelligent system of chronological sequence; and thus the desultory and often misdirected labours of the antiquary have given place to researches characterised by scientific accuracy.

The system of primitive archæology thus introduced has since been modified and carried out into ampler details, as the fruit of more extended discoveries, chiefly effected in France and England; but the three primary divisions, the Stone, the Bronze, and the Iron Periods, are still retained. The arrangement is warranted alike by evidence and by its practical convenience, though later research has given to the stone period a comprehensiveness undreamt of before, and so led to its subdivision into two ages of prolonged duration, with distinctive characteristics of primitive art. (1.) The Stone Period, as the name implies, is that in which the rude aboriginal arts, which the commonest necessities of man call into operation, are assumed to have been employed entirely on such available materials as stone, horn, bone, &c. (2.) The Bronze Period may in like manner admit of subdivision, though the term is conveniently employed, in its most comprehensive sense, for that era of progress in which the metallurgic arts appear to have been introduced and slowly developed—first, by the simple use of native copper, followed by the application of fire, the construction of moulds, and the discovery of such chemical processes as the alloying of copper and tin, and the consequent production of the beautiful and useful alloy which gives name to this the earlier metallurgic era. (3.) The Iron Period marks the era of matured metallurgic arts, and the accompanying progress consequent on the degree of civilisation which is the inevitable concomitant of such a state of things. While, however, those divisions hold good in their general application, they must not in every case be applied too rigidly. The archæologist is constantly recalled to the distinction between the researches of the palæontologist, as dealing with the traces of organic life, and his own study of the works of a rational being marked by all the diversities traceable to the reasoning and volition of the individual workman. Local facilities have also modified the arts of primitive man in various ways. In some localities, as in North America, pure native copper abounds; while on the other hand, in certain districts of Africa iron occurs in such a condition that it appears to have been wrought by the primitive metallurgist from very remote times.

All those periods embrace eras concerning which no contemporary written records exist; and in relation to most of them nearly as little is known directly as of the older periods with which the geologist exclusively deals. It need not therefore excite surprise that the process of induction established on this basis has been challenged by historical writers of high standing, but whose exclusive labours on the records of periods admitting of documentary evidence and charter proof render them little disposed to sympathise with a course of reasoning relative to the history of man, such as has, in the hands of the geologist, revealed so much in relation to more ancient life. The further, however, that research is pursued, alike into the habits of living races of savages, and into the characteristics of the oldest traces of primitive art, the more clearly does such a process of development, from the first rude working in stone to the highest arts of the skilled metallurgist, become manifest.

The Australians, the Maories of New Zealand, and the whole widely-scattered races of the Polynesian Islands, the Caribs and other natives of the American archipelago, with all the nomade tribes of the New World, from Patagonia to the Arctic circle, were, when first discovered, without any knowledge of the metals as such, and supplied their wants by means of implements and weapons of stone, shell, bone, or wood. The civilised Mexicans and Peruvians, on the contrary, when first visited by the Spaniards in the 16th century, were familiar with the working of copper as well as gold,—though totally ignorant of iron, and also retaining for common purposes many of the primitive stone weapons and implements, only substituting the abundant obsidian of their volcanic region for flint. Greece passed from its bronze to its iron age within the period embraced in its literary history; and the mastery of the art of working the intractable iron ore is traceable with tolerable clearness in the early history of Rome, not very long before it came in contact with the trans-Alpine barbarians. Among most of the Germanic and Celtic tribes iron appears to have been already known when they first came in contact with the aggressive civilisation of the south; and from one of them, the Norici (in whose country, in the Austrian valleys of the Danube, this metal is still wrought with the highest skill), there is reason to believe that the Romans acquired the art of making steel.

If history is only to begin, as that of Britain has been made to do, with the date of the first collision with invading Rome, then, no doubt, stone and bronze periods are as meaningless as are eocene and miocene periods to the geologist who assigns the Mosaic deluge as the source of the earliest phenomena of his science. To those, however, who are willing to follow inductive reasoning to its legitimate conclusions it must be apparent that it is no visionary theory, but a system founded in well-established truth, which arranges the archæological records of primitive history and the remains of human art into stone, bronze, and iron periods. Even here, however, an important distinction in the employment of such materials as a basis of inductive reasoning indicates the greatness of the revolution involved in the introduction among the living creatures inhabiting this earth of a being endowed with intelligence, and supplementing the natural resources of animal life by arts even of the most primitive kind. It must indeed be borne in remembrance that geological and historical chronology are very different things, and that the idea implied in the contemporaneousness of strata bears a very slight approximation to the coincidence of contemporaneous events and productions of an historical era. The doctrine of geological continuity is indeed challenged in certain respects; but on the whole, the geological formations, with their included organic remains, may be assumed to obey a natural and unvarying order; and so, within the compass of geological periods, to be of contemporaneous origin. But, notwithstanding certain extreme assumptions, based on the theory of evolution, and involving the consequent existence of man in remote geological eras, so far as all actual evidence can yet guide us, it is correct to say that, geologically speaking, the entire history of man is embraced in one period. But in the works of art, which form the bases of archæological induction, a new element—that of mind, or the reasoning faculty, along with the imitative and social arts—is introduced, and greatly complicates its subdivisions. The stone period of Britain or Denmark is analogous to that of the Polynesian Islands. So closely do their tools and weapons resemble each other that it requires a practised eye to distinguish the stone axe or flint lance-head found in an ancient British barrow from implements brought by some recent voyager from the islands of the Southern Ocean. Nor could the most experienced archæologist undertake in every case to discriminate between the flint arrow-head dug from some primitive barrow of undated centuries before the Christian era, and the corresponding weapon brought by some recent traveller from Tierra del Fuego or regions beyond the Rocky Mountains. The inference is therefore legitimate, that in those Polynesians, Fuegians, or Indians of the North-West, we have examples of tribes in the same primitive stage as were the aborigines of Europe during its stone period. Chronologically, however, the stone period of Europe and that of the Pacific islands or the American continent are separated by thousands of years. In like manner, the bronze age of Mexico was undisturbed by all later elements when first brought into contact with the matured civilisation of Europe in the 16th century, while the close of that of Britain preceded the 1st century of our era. The same rule is applicable to the primitive archæology of all countries; and a fertile source of error and misconception has already had its rise in the assumption that because Greece and Italy, Germany, Gaul, Scandinavia, and Britain, have all had their primitive stone and bronze periods, therefore the whole must have been contemporaneous. It cannot therefore be too strongly enforced as one of the most essential points of variance in the reasoning of the geologist and the archæologist, that the periods of the latter, though synonymous, are not necessarily synchronous; but that, on the contrary, nearly all the phenomena which pertain to the *natural history* of man, and to the historic development of the race, may be witnessed in their various stages in contemporary races of our own day—from rudimentary barbarism, and the absence of all arts essential to the first dawn of civilisation, to a state of greatest advancement in the knowledge and employment of such arts.

Some progress has already been made in an approximation to certain chronological data of much importance relative to such primitive periods of the history of nations. But the archæologist, as well as the geologist, is learning to deal with periods of time which cannot always be measured either by years or centuries, but rather must be gauged by those chronological stages in the history of our planet in which epochs and periods take the place of definite subdivisions of solar time. Nevertheless, geological evidence of changes which are known to have occurred within the historic period supplies an important key to the approximate duration of certain eras characterised by traces of human art; and while by the intelligent observation of such remains in the superficial strata, mingling with the fossil evidences of extinct and familiar species of animal life, the link is supplied by which man takes his place in an unbroken chain of creative existence, sweeping back into so remote a past, the evidences of matured art pertaining to periods unrecorded by history supply later links of the same chain, and reunite the present with all former ages.

The system of primitive archæology which is found applicable to British antiquities so closely corresponds in all its essential features to that of Europe prior to the era of authentic history, that the purpose of such an abstract as this will be most conveniently accomplished by presenting its leading points as examples of the whole, illustrating these in passing by the analogous remains discovered in other countries. The apparent simplicity of a primitive stone period has been considerably modified by recent research; and the careful study of the remains of ancient art, in their relation to accompanying geological phenomena, or of the evidences of artificial deposition in caves, barrows, chambered cromlechs, cairns, or other sepulchral structures, suggests the subdivision of prehistoric archæology into a succession of epochs included within the period of non-metallurgic arts.

But before defining the archæological subdivisions of time it is indispensable to glance at the palæontological elements of the question, and the evidences they supply in relation to comparative chronology. One of the most remarkable phenomena affecting the conditions of life in Europe in recent geological epochs is the existence of a period, of long duration throughout the northern hemisphere, of a temperature resembling that of the Arctic regions at the present time. After a period more nearly approximating in its conditions the heat of the tropics at the present day, though otherwise under varying states towards the end of the tertiary epoch the temperature of the whole northern hemisphere gradually diminished, until the mountainous regions of Scotland and Wales—then probably of a much higher elevation—resembled Greenland at the present time; and this Arctic temperature gradually extended southwards to the Alps and the Pyrenees. The glaciers formed under the influence of perpetual frost and snow descended from those and other mountains into the valleys and plains over the greater portion of central Europe and northern Asia; and this condition of things, pertaining to what is known as the *glacial period*, was one of greatly prolonged duration.

After some partial modifications of this low temperature, and a consequent advance and retrocession of the glacial influences in France and elsewhere, along what was then the border lines of a north temperate zone, the glacial period drew to a close; a gradual but persistent rise of temperature carried the lines of ice and perpetual snow further and further northward, excepting in regions of great elevation, as in the Swiss Alps. This was necessarily accompanied by the melting of the vast glaciers accumulated in the mountain valleys throughout the protracted period of cold. The broken rocks and soil of the highlands were swept into the valleys by torrents of melted ice and snow; the lower valleys were hollowed out and re-formed under this novel agent; and the landscape received its present outlines of valley, estuary, and river-beds from the changes wrought in this *diluvian epoch*. The enormous power of the torrents thus acting continuously throughout a period of prolonged duration, and the vast deposits of sand, gravel, and clay, with the embedded remains of contemporaneous animal and vegetable life with which they everywhere covered the plains, were viewed till recently solely in relation to the Mosaic narrative of a universal deluge, and were referred implicitly to that source. But recent though the epoch is when compared with older geological periods, its antiquity is enormous in relation to historic chronology; and instead of being the product of a sudden cataclysm of brief duration, it represents phenomena which required a period of long protracted centuries for their evolution.

Within this late tertiary, or quaternary, period are found the remains of animal life contemporary with primeval man and his earliest arts. The very characteristics of some of the fossil mammals of the period, so diverse from all that we have been accustomed to associate with man, help to suggest ideas of even an exaggerated antiquity for the era to which they are assignable, and to relegate it to the remotest conceivable antiquity consistent with all other evidence of the oldest traces of man or his arts seemingly contemporaneous with them. Of those now wholly extinct, the mammoth or *Elephas primigenius*, the *Elephas antiquus*, the *Rhinoceros tichorinus*, the *Hippopotamus major*, and such great cave carnivora as the *Ursus spelæus* and the *Felis spelæa*, are most noticeable for their great size, and in some cases for their enormous destructive powers, in striking contrast to the seemingly helpless condition of primitive man. Yet even some of those formidable mammalia probably owed their extinction fully as much to the presence of man as to any change in temperature and consequent alteration in the required conditions of climate and habitat. We are accustomed to regard the lion, tiger, leopard, panther, and others of the great *Felidæ* as pertaining exclusively to tropical countries. They are in reality limited to tropical jungles and uncultivated regions of great extent, where the abundance of wild vegetable-feeding animals supplies their food. The existence of neither is compatible with the presence of man in any great numbers; but in his absence those beasts of prey greatly extend their range. The Indian tiger not only follows the antelope and deer in the Himalayan chain to the verge of perpetual snow, but the tiger, leopard, panther, and cheetah hunt their prey beyond that mountain range, even into Siberia.

The influence of man in the extirpation of the wild fauna is illustrated by another class of extinct animals of many historical regions, which yet survive in more favourable localities. The discovery of abundant evidence of a period in the history of central and southern France when the reindeer (*Cervus tarandus*) formed one of the chief sources both for the food of man and for the materials from which his weapons and implements were made, seems to carry us back to an era, inconceivably remote, when central France was in the condition of Lapland in mediæval or still earlier centuries. But the climate of North Britain is not even now incompatible with the existence of the reindeer, and its favourite moss abounds in many parts of the Highlands. It need not therefore surprise us to learn that traces of the reindeer are by no means rare in Scotland; and numerous examples of its horns have recently been recovered in more than one Caithness locality, with the marks of sawing and cutting for artificial use, and lying among other remains in stone-built structures of a primitive population of North Britain. How old they are may not be strictly determinable, but they help us to the acceptance of a very modern date for the presence of the reindeer there; for Torfæus states that so recently as the twelfth century the Jarls of Orkney were wont to cross the Pentland Firth to chase the roe and the reindeer in the wilds of Caithness. At the same date also we find the skin of the beaver rated for customs duties amongst articles of Scottish export specified in an Act of the reign of David I.

Another very characteristic animal pertaining to the prehistoric era of European man is the *Megaceros Hibernicus*, or gigantic Irish elk. Its bones occurred with those of the *Elephas primigenius*, the *Rhinoceros tichorinus*, the *Ursus spelæus*, and other extinct mammals, alongside of human remains and works of art, in the famous Aurignac cave of the Pyrenees; and in the recently-explored Brixham cave, on the Devonshire coast, similar remains of the fossil rhinoceros, horse, and reindeer, as well as of several extinct carnivora, lay embedded in the same breccia with flint knives. And not only have the horns and bones of the *Megaceros Hibernicus* been recovered from Irish bogs and marl-pits, with marks of artificial cutting, but a rude Irish lyre, found in the moat of Desmond Castle, Adare, has been pronounced by Professor Owen to be made from the bone of this extinct deer.

So is it with the ancient *Bovidæ*, not only adapted for the chase, but suitable for domestication; such as the *Bos primigenius*, the *Bos longifrons*, and the *Bison priscus*. Their remains have been found in submarine forests, or mingling in the drift or cave deposits with the *Elephas primigenius*, the *Felis spelæa*, and others of the most gigantic fossil mammals; while abundant traces reveal their existence not merely contemporaneous with man, but within definite historical periods.

The great alluvial valley of the river Forth has yielded another class of relics connecting the gigantic fossil mammalia of a prehistoric epoch with man. The disclosures of the Carse of Falkirk have repeatedly included remains of the *Elephas primigenius:* and in at least one case its tusks were found in such perfect condition as to be available for the ivory-turner, though lying embedded at a depth of 20 feet in the boulder clay. But in the neighbouring valley of the Forth the fossil whale (*Balænoptera*) has not only been repeatedly found far inland, buried in the alluvial soil, at levels varying from 20 to 25 feet above high-water mark, but in at least two instances the rude lance or harpoon of deer's horn lay alongside of the skeletons; and near another of them were found pieces of stag's horn, artificially cut, and one of them perforated with a hole about an inch in diameter. Flint implements, an oaken quern, and other ingenious traces of primitive art, recovered from the same alluvial soil, all tell of a time when the British savage hunted the whale in the shallows of a tide at the base of the Ochil hills, now between 20 and 30 feet above the highest tides and 7 miles distant from the sea.

There is no doubt that the disappearance of the whale from the British shores, like the reindeer from its northern valleys, is due far more to the presence of man than to any change of temperature so greatly affecting the conditions of life as to involve their extinction. Nevertheless it is convenient to recognise in the disappearance of such emigrant species from the historic areas the close of the palæontological age. The Urus, the Aurochs, the *Bos longifrons*, or native ox of the Roman period, and others of that important class of animals which man first began to turn to account for domestication, have also ceased to exist among European fauna; but this is clearly traceable to the destructive presence of man. Within three or four centuries the Urus (*Bos primigenius*) was still known in Germany; the Aurochs (*Bos priscus*) is even now preserved under special protection in Lithuania; and herds of British wild cattle in Cadzow forest, Lanarkshire, and at Chillingham Park, Northumberland, perpetuate varieties otherwise extinct.

Reverting, then, to the classification which prehistoric archæology admits of, in the light of its most recent disclosures, it appears to be divisible into four distinct epochs, of which the first two embrace successive stages of the age of stone implements.

1. The *Palæolithic Period* is that which has also been designated the Drift Period. The troglodytes, or cave-dwellers, of this primitive era were to all appearance contemporaneous with the mammoth, the woolly-haired rhinoceros, and the great cave carnivora already named. In England, France, Belgium, and other countries of Europe, numerous caves have been explored which were undoubtedly the habitations and workshops of the men of this period. These caverns vary in character and dimensions according to the geological features of the localities where they occur; but all alike involve the simple feature

of recesses, more or less ample, affording comparatively dry and commodious shelter, and so being resorted to as places of habitation alike by wild animals and by man himself But the most valuable for the purposes of the archæologist are a class of caverns which occur in limestone districts, and which, from the combined mechanical action of the water operating on a rock easily eroded, and its chemical action when charged with a certain amount of carbonic acid in dissolving the calcareous rock, are found expanded into long galleries and chambers of large dimensions. There the same chemical agents, acting under other circumstances, have dissolved the limestone rock, and sealed up the ancient flooring at successive intervals, thereby furnishing a test of the duration of long periods of alternate action and repose, and yielding evidence of the most indisputable kind as to the order of succession of the various deposits and their included bones and implements.

In Belgium, at Dordogne, and in some parts of the south of France, the caves and rock-recesses are of a much simpler character. Yet there also favouring circumstances have preserved contemporary deposits of the ancient cave-dwellers, their works of art, the remains of their food, and even their cooking hearths.

The caves of the drift period accordingly present peculiarly favourable conditions for the study of the post-pliocene period. Some of these caverns were evidently first occupied by the extinct carnivora of that period, as in the case of the famous Kent's Hole Cave of Devonshire, of which the lowest deposit is a breccia of water-worn rock and red clay, interspersed with numerous bones of the *Ursus spelæus*, or great cave-bear. Over this a stalagmitic flooring had been formed, in some places to a depth of several feet, by the long-protracted deposition of carbonate of lime held in solution in the drippings from the roof. Above this ancient flooring, itself a work of centuries, later floods had superimposed a thick layer of "cave-earth," in some cases even entirely filling up extensive galleries with a deposit of drift-mud and stones, within which are embedded the evidences of contemporaneous life—bones and teeth of the fossil elephant, rhinoceros, horse, cave-bear, hyæna, reindeer, and Irish elk; and along with these, numerous weapons and implements of chipped flint, horn, and bone—the unmistakable proofs of the presence of man. These, again, have been sealed down, in another prolonged period of rest, by a new flooring of stalagmite; and thus the peculiar circumstances of those cave deposits render them specially favourable for the preservation of a coherent record of the period. Here are the evidences of the animal life contemporaneous with the men of the caves during the drift period, here also are many of their smaller flint implements—the flint-cores and the chips and flint-flakes, showing where their actual manufacture was carried on; and the lances, bodkins, and needles of bone, which could only have been preserved under such favouring circumstances.

But besides the actual deposits in the caves, the river gravels of the same period have their distinct disclosures. The spear-heads, discs, scrapers, and other large implements of chipped flint are of rare occurrence in the cave breccia. Their size was sufficient to prevent their being readily dropt and buried beyond reach of recovery in the muddy flooring of the old cave dwelling; and the same cause preserved them from destruction when exposed to the violence involved in the accumulation of the old river drifts. In the north of France, and in England from Bedfordshire southward to the English Channel, in beds of ancient gravel, sand, and clay of the river valleys, numerous discoveries of large flint implements have been made—from the year 1797, when the first noted flint implements of the drift were discovered in the same stratified gravel of Hoxne, in Suffolk, in which lay bones of the fossil elephants and other extinct mammalia. The characteristics of the river-drift implements, as well as of the whole art of the stone age, have been minutely described and illustrated in various works, but especially in Evans's *Ancient Stone Implements, Weapons, and Ornaments of Great Britain.* It is sufficient, therefore, to refer to such authorities for details.

But besides the numerous specimens of the manufactures in flint, horn, and bone, illustrative of the mechanical ingenuity of this primitive era, special attention is due to the actual evidences of imitative and artistic skill of the sculptors and draughtsmen of the same period.

Different attempts have been made, especially by French *savans*, to subdivide the palæontologic age of man into a succession of periods, based chiefly on the character of the mammalian remains accompanying primitive works of art; and the two great subdivisions of the elephantine or mammoth age and the reindeer age have been specially favoured. Among the works of art of the cave-men of Perigord, in central France, contemporary with the reindeer, various drawings of animals, including the reindeer itself, have been found incised on bone and stone, apparently with a pointed implement of flint. But the most remarkable of all is the portrait of a mammoth, seemingly executed from the life, outlined on a plate of ivory found in the Madelaine Cave, on the river Vezère, by M. Lartet, when in company with M. Verneuil and Dr Falconer. If genuine—and the circumstances of the discovery, no less than the character of the explorers, seem to place it above suspicion—this most ancient work of art is of extreme value. The skulls and other remains of five individuals have been found to illustrate the men of this period. The cerebral development is good, and alike in features and form of head they compare favourably with later savage races. Their drawings embrace animals, single and in groups, including the mammoth, reindeer, horse, ox, fish of different kinds, flowers, ornamental patterns, and also ruder attempts at the human form. They also carved in bone and ivory. Some of the delineations are as rude as any recent specimens of savage art, others exhibit considerable skill; but the most remarkable of all is the representation of the mammoth. It has been repeatedly engraved, and as, to all appearance, a genuine contemporary effort at the portraiture of that remarkable animal, its worth is considerable. But this sinks into insignificance in comparison with its value as a gauge of the intellectual capacity of the men of that remote age. It represents the extinct elephant, sketched with great freedom of hand, and with an artistic boldness in striking contrast to the laboured efforts of an untutored draughtsman. Whatever other inference be deduced from it, this is obvious, that in intellectual aptitude the palæolithic men of the reindeer period of central France were in no degree inferior to the average Frenchman of the 19th century.

2. This first or palæolithic period, with its characteristic implements of chipped flint, belonging to an epoch in which man occupied central Europe contemporaneously with the mammoth, the cave-bear, and other long-extinct mammals, was followed by the second or *Neolithic Period*, or, as it has been sometimes called, the Surface-Stone Period, in contradiction to the Drift Period, characterised by weapons of polished flint and stone. The discovery and exploration of the ancient *Pfahlbauten* or lake villages of Switzerland and other countries, including the crannoges of Ireland and Scotland, and of the *kjökken-möddings* or refuse-heaps of Denmark, Scotland, and elsewhere, have greatly extended the illustrations of this period, and given definiteness to the evidences of its antiquity. But while it thus includes works of a very remote epoch, it also

embraces those of later regular sepulture, with the sepulchral pottery of rudest type, the personal ornaments and other remains of the prehistoric races of Europe, onward to the dawn of history. It even includes the first traces of the use of the metals, in the employment of gold for personal adornment, though with no intelligent recognition of its distinction from the flint and stone in which the workmen of this neolithic period chiefly wrought.

The nearly indestructible nature of the materials in which the manufacturers alike of the palæolithic and the neolithic period chiefly wrought, helps to account for the immense number of weapons and implements of the two prolonged ages of stone-working which have been recovered. The specimens now accumulated in the famous collection of the Christiansborg Palace at Copenhagen amount to several thousands. The Royal Irish Academy, the Society of Antiquaries of Scotland, the British Museum, and other collections, in like manner include many hundreds of specimens, ranging from the remotest periods of the cave and drift men of western Europe to the dawn of definite history within the same European area. They include hatchets, adzes, gouges, chisels, scrapers, discs, and other tools in considerable variety; axes, lances, spear and arrow heads, mauls, hammers, and other weapons and implements of war and the chase; besides a variety of utensils, implements, and ornaments, with regard to which we can but vaguely guess the design of their construction. Many of these are merely chipped into shape, sometimes with much ingenuity, in other cases as rudely as the most barbarous and massive implements of the palæolithic period. But from their association, in graves or other clearly-recognised deposits of the later period, with ground and polished implements, and even occasionally with the first traces of a time when the metals were coming into use, there is no room to question their later origin. In part they may be legitimately recognised, like the whole elements of archæological classification, to mark different degrees of rudeness in successive steps towards civilisation; in part they indicate, as in manufactures of our own day, the economy of labour in roughly-fashioned implements designed only for the rudest work, or for missiles the use of which involved their loss.

To the same primitive period of rude savage life must be assigned the rudiments of architectural skill pertaining to the *Megalithic Age*. Everywhere we find traces, alike throughout the seats of oldest civilisation and in earliest written records, including the historical books of the Old Testament Scriptures, of the erection of the simple monolith, or unhewn pillar of stone, as a record of events, a monumental memorial, or a landmark. There is the Tanist Stone, or kingly memorial, like that set up in Shechem when Abimelech was made king; the Hoar Stone, or boundary-stone, like "the stone of Bohan, the son of Reuben," and other ancient landmarks of Bible story; the Cat Stone, or battle-stone, a memorial of some great victory; and the stone set up as the evidence of some special treaty or agreement, like Laban and Jacob's pillar of witness at Galeed. To the same primitive stage of architecture belong the cromlech, the cairn, the chambered barrow, and other sepulchral structures of unhewn stone; as well as the weems, or megalithic subterranean dwellings common in Scotland and elsewhere, until, with the introduction of metals and the gradual mastery of metallurgic art, we reach the period of partially hewn and symmetrical structures, of which the great temple of Stonehenge is the most remarkable example. But it is in Egypt that megalithic architecture is seen in its most matured stage, with all the massiveness which so aptly symbolises barbarian power, but also with a grandeur, due to artistic taste and refinement, in which the ponderous solidity of vast megalithic structures is relieved by the graces of colossal sculpture and of an inexhaustible variety of architectural detail. There appears to be a stage in the development of the human mind in its progress towards civilisation when an unconscious aim at the expression of abstract power tends to beget an era of megalithic art. The huge cromlechs, monoliths, and circles still abounding in many centres of European civilisation perpetuate the evidence of such a transitional stage among its prehistoric races. But it was in Egypt that an isolation, begot by the peculiar conditions of its unique physical geography, though also perhaps ascribable in part to certain ethnical characteristics of its people, permitted this megalithic art to mature into the highest perfection of which it is capable. There the rude unhewn monolith became the graceful obelisk, the cairn was transformed into the symmetrical pyramid, and the stone circles of Avebury and Stonehenge, or the megalithic labyrinths of Carnac in Brittany, developed into colonnaded avenues and temples, like those of Denderah and Edfu, or the colossal sphinx avenue of Luxor.

Elaborately-finished axes, hammer-heads, cups, and vases of the late neolithic era serve to illustrate the high stage to which the arts of a purely stone period could be advanced, in the absence of any process of arrestment or change. But long before such a tendency to development into ornamental detail and symmetrical regularity of construction could be brought to bear on the megalithic architecture of the same era, the metallurgic sources of all later civilisation had begun to supersede its rude arts. To such remote eras we strive in vain to apply any definite chronology. At best we work our way backwards from the modern or known into the mysterious darkness of remotest antiquity, where it links itself to unmeasured ages of geological time. But by such means science has been able to add a curious chapter to the beginnings of British and of European story, involving questions of mysterious interest in relation to the earliest stages in the history of man. The very characteristics which distinguish him in his rudest stage from all other animals have helped from remotest times to perpetuate the record of his progress.

The evidences of the various acquirements and degrees of civilisation of the prehistoric races of Britain are derived not only from weapons, implements, pottery, and personal ornaments found deposited in ancient dwellings and sepulchres; but from still older traces supplied by chance discoveries of the agriculturist, miner, and builder, such as the implements of the ancient whalers of the Forth, or the monoxylous oaken canoes dug up from time to time in the valley of the Clyde, or even beneath some of the most ancient civic foundations of Glasgow. Both alike pertain to areas of well-defined historical antiquity, from the very dawn of written history, or of literate chronicles in any form; and both also have their geological records, preserving the evidence of changes of level in unrecorded centuries subsequent to the advent of man, when the whales of the Forth and the canoes of the Clyde were embedded in the alluvium of those river-valleys, and elevated above the ancient tide-marks of their estuaries. Another change of level, possibly in uninterrupted continuance of the ancient upheaval, has been in progress since the Roman invaders constructed their military roads, and built their wall between the Forth and the Clyde, in the 1st and 2d centuries of the Christian era.

By evidence such as this a starting-point is gained whence we may confidently deduce the colonisation of the British Islands, and of the north of Europe, at periods separated by many centuries from that in which our island first figures in history. The researches of the ethnologist add to our knowledge of this unrecorded era, by disclosing some of the physical characteristics of the aboriginal races, derived from human remains recovered in cave-drifts, ancient mining shafts, bogs, and marl-pits, or found in the most ancient sepulchres, accompanied by rudest evideuces of art; and the researches of Nillson, Eschricht, Gosse, Rathke, Broca, and other Continental ethnologists, along with those which have been carried on with minute care in the British Islands, disclose characteristic cranial types indicating a succession of prehistoric races different from the predominant types belonging to the historical period of Europe; and some of them probably contemporaneous with the changes indicated in the periods of archæological time.

The very latest stage of archæological antiquity, when it seems to come in contact with the dawn of historic time, was unquestionably one of complete barbarism, as is sufficiently apparent from its correspondence to that which the intercourse with European voyagers is bringing to a close among the islands of the Pacific. The ancient Scottish subterranean dwellings termed weems (Gaelic *uamhah*, a cave), or "Picts' houses," have been frequently found, apparently in the state in which they must have been abandoned by their original occupants; and from those we learn that their principal aliment must have been shell-fish and crustacea, derived from the neighbouring sea-beach, along with the chance products of the chase. The large accumulations of the common shell-fish of our coasts found in some of those subterranean dwellings is remarkable; though along with such remains the stone quern or hand-mill, as well as the ruder corn-crusher or pestle and mortar, repeatedly occur; supplying the important evidence that the primitive nomade had not been altogether ignorant of the valne of the cereal grains.

The source of change in Britain, and throughout Europe, from this rude state of barbarism, is clearly traceable to the introduction of metals and the discovery of the art of smelting ores. Gold was probably the earliest metal wrought, both from its attractive appearance, and from its superficial deposits, and the condition in which it is frequently found, rendering its working an easy process. Tin also, in the south of Britain, was wrought at the very dawn of history: and, with the copper which abounds in the same district of country, supplied the elements of the new and important compound metal, bronze.

3. This accordingly indicates the transition from the later stone age to the third or *Bronze Period*, which, beginning apparently with the recognition of the native copper as a malleable metal, and then as a material capable of being melted and moulded into form by the application of heat, was followed up by the art of smelting the crude ores so as to extract the metal, and that of mixing metals in diverse proportions so as to prepare an alloy of requisite ductility or hardness, according to the special aims of the artificer.

Along with the full mastery of the working in copper and bronze the skill of the goldsmith was correspondingly developed; and the ornaments of this period, including torques, armlets, beads, and other personal decorations and insignia of office, wrought in gold, are numerous, and often of great beauty. The pottery of the same period exhibits corresponding improvement in material, form, and ornamentation; though, considering the mimetic and artistic skill shown in the drawings and carvings of the remotest periods, it is remarkable that the primitive pottery of Europe is limited, alike in shape and decoration, to purely arbitrary forms. This in its crudest conventionalism consists almost exclusively of varieties of zigzag patterns scratched or indented on the soft clay. This primitive ornamentation seems so natural, as the first æsthetic promptings of the human mind, that it is difficult, if not in some cases impossible, to distinguish between the simple pottery of comparatively recent origin, recovered on the sites of old American Indian villages, and primitive pottery obtained from British barrows pertaining to centuries long prior to the Christian era. But the fictile ware exhibits an improvement in some degree corresponding to that of the metallurgic art, which everywhere throughout Europe furnishes weapons, implements, and personal ornaments of the bronze period, characterised by much grace and delicacy in form, and by an ornamentation peculiar in style, but not unworthy of the novel forms and material

It was long assumed, alike by historians and antiquaries, that the beautiful bronze swords, spear-heads, shields, torques, armillæ, &c., so frequently discovered, were mere relics of foreign conquest or barter, and they were variously assigned to Egyptian, Phœnician, Roman, or Danish origin. But this gratuitous assumption has been disproved by the repeated discovery of the moulds for making them, as well as of the refuse castings, and even of beds of charcoal, scoriæ, and other indications of metallurgy, on the sites where they have been found. It has not escaped notice, however, that the transition appears to be an abrupt one from stone to bronze, an alloy requiring skill and experience for its use; and that few examples are recorded of the discovery of copper tools or weapons, though copper is a metal so easily wrought as to have been in use among the Red Indians of America. The inference from this fact is one which all elements of probability tend to confirm, viz., that the metallurgic arts of the north of Europe are derived from a foreign source, whether by conquest or traffic; and that in the beautiful bronze relics so abundant, especially in the British Islands and in Denmark, we see the fruits of that experience which the more ancient civilisation of Egypt and Phœnicia had diffused. The direct intercourse between the countries on the Mediterranean and the Cassiterides, or Tin Islands,—as the only known parts of the British Islands are called in the earliest allusions which are made to them by Herodotus, Aristotle, and Polybius,—abundantly accounts for the introduction of such knowledge to the native Britons at a very remote period. Phœnician and Carthaginian merchant ships traded to Cornwall centuries before the white cliffs of Albion were first seen from the Roman war-galleys. Greece also, not improbably, proved a mediator in this all-important transfer. It is at least to be noted that the forms of weapons, and especially of the beautiful "leaf-shaped sword," as figured on the most ancient painted Greek vases, closely correspond to the most characteristic relics of the bronze period in the north of Europe and the British Isles.

In reviewing the characteristics of this bronze period, the disclosures of native art on the American continent supply some singularly interesting and suggestive illustrations. There, throughout the whole northern regions of the North American continent and in the ruder areas of South America, as well as in the West Indian archipelago, a population was found consisting exclusively of rude nomad hunters, in a pure stone period of primitive savage art. Nor does it at all conflict with this that they were to a certain extent familiar with the resources of the rich copper regions of Lake Superior, where that metal is found in enormous masses in a malleable state. This they procured, and not only themselves employed it in the manufacture of weapons, implements, and personal ornaments, but distributed it by barter far down the Ohio and Mississippi valleys, and eastward to the great lakes, to the St Lawrence valley, and to the Hudson river. Silver and lead are also found in the same rich mineral region in metallic crystals, and were not unknown to the native tribes. But everywhere those metals were cold-wrought, as a mere malleable stone capable of being hammered into any desired shape, but in total ignorance of the influence of fire or the use of alloys.

But wholly distinct from its rude Indian tribes, North America had its semi-civilised Mexicans and South America its more highly civilised Peruvians, who had learned to mine and smelt the ores of the Andes, and make metallic alloys wherewith to fashion for themselves bronze tools of requisite hardness for quarrying and hewing the solid rock. With these they sculptured the statues of their gods, and reared palaces, temples, and pyramids, graven with elaborate sculptures and hieroglyphics by a people wholly ignorant of iron, which have not unjustly suggested many striking analogies with the megalithic art of ancient Egypt. The *huacas*, or tombs of the Incas of Peru, and also their royal depositories of treasure, have disclosed many remarkable specimens of elaborate metallurgic skill,—bracelets, collars, and other personal ornaments of gold; vases of the same abundant precious metal, and also of silver; mirrors of burnished silver, as well as of obsidian; finely-adjusted silver balances; bells both of silver and bronze; and numerous common articles and tools of copper, or of the more efficient alloy of copper and tin,—all illustrative of the arts and civilisation of a purely bronze age.

4. The fourth or *Iron Period* is that in which the art of smelting the ores of the most abundant metal had at length been mastered; and so iron superseded bronze for arms, sword-blades, spear-heads, axes, daggers, knives, &c. Bronze, however, continued to be applied to many purposes of personal ornament, horse furniture, the handles of swords and other weapons; nor must it be overlooked that flint and stone were still employed for lance and arrow-heads, sling-stones, and other common purposes of warfare or the chase, not only throughout the whole bronze period, but far into the age of iron. The discovery of numerous arrow-heads, or flakes of black flint, on the plain of Marathon, has been assumed with good reason to point to the use of such rude weapons by the barbarian host of Darius; and the inference is confirmed by the facts which Herodotus records, that Ethiopian auxiliaries of the army of Xerxes, ten years later, were armed with arrows tipped with stone.

The essential change resulting from the maturing of the iron period lies in the unlimited supply of the new metal. Had bronze been obtainable in sufficient quantity to admit of its application to the endless purposes for which iron has since been employed, the mere change of metal would have been of slight significance. But the opposite was the case. The beautiful alloy was scarce and costly; and hence the arts of the neolithic period continued to be practised throughout the whole duration of the age of bronze. But iron, though so abundant in its ores, requires great labour and intense heat to fuse it; and it needed the prolonged schooling of the previous metallurgic era to prepare the way for the discovery of the properties of the ironstone, and the processes requisite to turn it to account. Iron, moreover, though so abundant, and relatively of comparatively recent introduction, is at the same time the most perishable of metals. It rapidly oxidises unless protected from air and moisture, and hence few relics of this metal belonging to the prehistoric period have been preserved in such a state as to illustrate the skill and artistic taste of the fabricators of that last pagan era, in the way that the implements of the three previous periods reveal to us the habits and intellectual status of those older times.

But the iron is the symbol of a period in which pottery, personal ornaments of the precious metals, works in bronze, in stone, and other durable materials, supply ample means of gauging the civilisation of the era, and recognising the progress of man in the arts, until we come at length to connect their practice with definite historical localities and nations, and the names of Egypt and Phœnicia, of Gadir, Massilia, the Cassiterides, and Noricum, illuminate the old darkness, and we catch the first streak of dawn on a definite historical horizon. Thus, with the mastery of the metallurgic arts is seen the gradual development of those elements of progress whereby the triumphs of civilisation have been finally achieved, and man has advanced towards that stage in which the inductive reasonings of the archæologist are displaced by records more definite, though not always more trustworthy, as the historian begins his researches with the aid of monumental records, inscriptions, poems, and national chronicles.

Within the later iron period, accordingly, we reach the era of authentic history. There is no room for doubt that whatever impetus the Roman invasion may have given to the working of the metals in Britain, iron was known there prior to the landing of Julius Cæsar. Within this archæological period, however, the examples of Roman art and the influences of Roman civilisation begin to play a prominent part. To this period succeed the Saxon and Scandinavian eras of invasion, with no less characteristic peculiarities of art workmanship, as well as of sepulchral rites and social usages. In these later periods definite history comes to the aid of archæological induction, while those intermediate elements of historical re-edification, the inscriptions on stone and metal, and the numismatic series of chronological records, all unite to complete a picture of the past replete with important elements for the historian.

The connection between archæology and geology has been indicated, but that between archæology and ethnology is of much more essential significance, and is every day being brought into clearer view. By the investigation of the tombs of ancient races, and the elucidation of their sepulchral rites, remarkable traces of unsuspected national affinities are brought to light; while a still more obvious correspondence of arts in certain stages of society, among races separated alike by time and by space, reveals a uniformity in the operation of certain *human instincts*, when developed under nearly similar circumstances, such as goes far to supply a new argument in proof of the unity of the human race.

The self-evident truths confirmatory of the principles upon which this system of primitive archæology is based, may be thus briefly summed up:—Man, in a savage state, is to a great extent an isolated being; co-operation for mutual and remote advantage, except in war and the chase, is scarcely possible; and hence experience at best but slowly adds to the common stock of knowledge. In this primitive stage of society the implements and weapons which necessity renders indispensable are invariably supplied from the sources at hand; and the element of time being of little moment, the rude workman fashions his stone axe or hammer, or his lance of flint, with an expenditure of labour such as, with the appliances of civilisation, would suffice for the manufacture of hundreds of such implements.

The discovery of the metallurgic arts, by diminishing labour and supplying a material more susceptible of varied forms as well as of ornamentation, and also one originating co-operation by means of the new wants it calls into being, inevitably begets social progress. The new material, moreover, being limited in supply, and found only in a few localities, soon leads to barter, and thence to regular trade; and thus the first steps towards a division of labour and mutual co-operation are made. So long, however, as the metal is copper or bronze, the limited supply must greatly restrict this social progress, while the facilities for working it admit of that isolation so natural to man in a rude state; and these, added to the frequent discovery of copper, in its natural condition much more nearly resembling a ductile metal than the ironstone, abundantly account for its use having preceded that of the more abundant metal.

Great experience must have been acquired in earlier metallurgy before the iron ore was attempted to be wrought. In this, co-operation was indispensable; but that once secured, and the first difficulties overcome, the other results appear inevitable. The supply is inexhaustible, widely diffused, and procurable without excessive labour. The material elements of civilisation were thereby rendered available, and all succeeding progress might be said to depend on the capacity of the race.

The simplicity which characterises the archæological disclosures of Scandinavia, Germany, Ireland, and other regions of trans-Alpine Europe lying outside of the range of ancient Greek or Roman influences, has contributed some important aids to the study of prehistoric arts; but the full significance of their teachings has yet to be tested by comparison with the primitive arts pertaining to Egypt, Greece, Asia Minor, and other ancient centres of earliest civilisation. To this certain singularly interesting disclosures of very recent date, which some have regarded as at variance with the foregoing classification of archæological epochs, help to furnish the desired materials. The researches of Dr Heinrich Schliemann on one of the most memorable sites which epic poetry has selected for the mythic beginnings of history, have brought to light what he believes to be actual remains of the Troy of the *Iliad*. Dr Schliemann began his systematic explorations in 1871, and pursued them, during the available seasons, till the month of June 1873. With patient assiduity the accumulated debris on the scene of ancient civic settlement was sifted and opened up by regular excavations, till the natural rock was exposed at a depth of upwards of 50 feet. Throughout the whole of this, abundant traces of former occupation were brought to light; and so great an accumulation of debris and rubbish upon an elevated site affords undoubted evidence of the vicissitudes of a long-settled centre of population. To this specific evidence lent additional confirmation. The foundations of a temple, supposed to be that of the Ilian Athena of the time of Alexander, along with coins, inscriptions, and numerous remains of architecture and sculpture, combined to fix the era of an ancient, but strictly historical, period. At a further depth of upwards of 6 feet, broken pottery, implements of bronze, and charred wood and ashes, showed the traces of an older settlement which had perished by fire. But the artificial character of the debris encouraged further research; and when the excavations had been carried to about double the depth, Dr Schliemann came upon a deposit rich in what may be styled neolithic remains: axes, hammers, spear-heads, and other implements of polished diorite or other stone, weights of granite, querns of lava, and knives and saws of flint abounded, associated with plain, well-executed pottery, but with only two pins of copper or bronze to indicate any knowledge of metal. Continued excavations brought to light additional stone implements and weapons; until at a depth of some 33 feet, well-wrought implements and weapons of bronze, and pottery of fine quality and execution, revealed the traces of an earlier civilisation on the same ancient site.

In all this, while there is much to interest, there is nothing to surprise us. Here, near the shores of the Hellespont, at a point accessible to the oldest known centres of civilisation,—to Egypt, Phœnicia, Assyria, Greece, Carthage, and Rome,—a civilised community, familiar with the arts of the bronze period of the Mediterranean shores, appears to have yielded to vicissitudes familiar enough to the student of ancient history. After a time the desolated locality tempted the settlement of some barbarian Asiatic horde, such as the steppes of that continent could furnish even now. They were ignorant of metallurgic arts; though probably, like the savage tribes of the New World at the present time, not wholly unaware of the manufacture of implements and weapons of bronze or other metals. Such a local alternation of bronze and stone periods in a region lying in close proximity alike to vast areas of Asiatic barbarism, and to the most important centres of ancient civilisation, in no degree conflicts with a general system of succession of archæological periods. Mexico and Peru, while in a purely bronze age, were overthrown by Spanish invaders. Large portions of their ancient territories were abandoned to utter barbarism, and even now are in the occupation of savage tribes. But the ancient city of Montezuma has been made the capital of a civilised state; the beds of its canals have been filled up, burying therein obsidian, stone, and bronze implements, pottery, sculptures, and much else pertaining to its ante-Columbian era; and it only requires such a fate as its modern history renders conceivable enough, to leave for future ages the buried strata of a civic site revealing similar evidences of the alternation of semi-civilised, barbarian, and civilised ages, on the same long-inhabited site of Toltecans and Aztecs Indian savages, and modern Mexicans and Spaniards.

That man has everywhere preceded history is a self evident truth. So long as no scientific evidence seemed to conflict with a long-accepted chronology in reference to the antiquity assigned to the human race, it remained unchallenged, though the like computation had been universally rejected in reference to the earth as the theatre of his history, and we were content to regard the prehistoric era of man as no more than a brief infancy of the race. But the investigations and disclosures of recent years in reference to the whole prehistoric period have involved of necessity a reconsideration of the grounds on which a definite antiquity of comparatively brief duration has been assigned to man; and the tendency at present is rather to exaggerate than to diminish the apparent antiquity of the race. The nature and extent of the evidence which has thus far rewarded intelligent research have been sufficiently indicated above; and as it is still far from complete, the student of archæology will act wisely in pushing forward his researches, and accumulating and comparing all available evidence, without hastily pronouncing any absolute verdict on this question. But, without attempting to connect with any historic chronology the men of the English drift, or the troglodytes of the mammoth or reindeer periods of France, it may be useful, in concluding this summary of primitive archæology, to glance at the origin of civilisation, and the evidences of the antiquity of what appear to constitute its essential elements.

Everywhere man seems to have passed through the same progressive stages: First, that of the *savage* or purely *hunter state;* a condition of precarious instability, in which man is most nearly in the state of a mere animal subsisting on its prey. It is the condition of nomad life, incompatible with a numerous or settled population; exhausting the resources of national being in the mere struggle for existence, and therefore inimical to all accumulation of the knowledge and experience on which human progress depends. In this primitive state, man is disclosed to us by the evidence with which the archæologist now deals. He appears everywhere in this first stage as the savage occupant of a thinly-peopled continent, warring with seemingly inadequate means against gigantic carnivora, the contemporary existence of which is known to us only by the disclosures of geological strata or ossiferous caves, where also the remains of still more gigantic herbivora confirm the idea of man's exhaustive struggle for existence. The nearest analogy to such a state of life is that of the modern Esquimaux, warring with the monstrous polar bear, and making a prey of the gigantic cetaceæ of Arctic seas. Through how many ages this unhistoric night of European man may have preceded the dawn of civilisation it is at present vain to speculate. But this is noticeable, that there is no inherent element of progress in a people in the condition of the Esquimaux. To all appearance, if uninfluenced by external impulse, or unaffected by any great amelioration of climate, they are likely to prolong the mere struggle for existence through unnumbered centuries, armed, as now, with weapons and implements ingeniously wrought of bone, ivory, and stone, the product of the neolithic arts of this 19th century.

To this succeeds the second or *pastoral state*, with its flocks and herds, its domesticated animals, and its ideas of personal property, including in its earlier stages that of property in man himself. It pertains to the open regions and warmer climates of the temperate zone, and to the elevated steppes and valleys of semi-tropical countries, where the changing seasons involve of necessity the wandering life of the shepherd. This accordingly prevents the development of the arts of settled life, especially those of architecture; and precludes all idea of personal property in the soil. But the conditions of pastoral life are by no means incompatible with frequent leisure, reflection, and consequent intellectual progress. Astronomy has its origin assigned to the ancient shepherds of Asia; and the contemplative pastoral life of the patriarchs Job and Abraham has had its counterpart in many an Arab chief of later times.

The third or *agricultural stage* is that of the tillers of the soil, the Aryans, the ploughers and lords of the earth, among whom are developed the elements of settled social life involved in the personal homestead and all the ideas of individual property in land. The process was gradual. The ancient Germans, according to the description of Tacitus, led the life of agricultural nomads, and such was the state of the Visigoths and Ostrogoths of later centuries. But this was in part due to the physical conditions of trans-Alpine Europe in those earlier centuries. Long ages before that, as the ancient Sanscrit language proves, the great Aryan family, of which those are offshoots, had passed from the condition of agricultural nomads to that of lords of the soil among a settled agricultural people. They had followed up the art of ploughing the soil with that of shipbuilding and "ploughing" the waves. They were skilled in sewing, in weaving, in the potter's art, and in masonry. Their use of numbers was carried as high at least as a hundred before they settled down from their nomad life. They had domesticated the cow, the sheep, the horse, and the dog, and their *pásu* or feeders already constituted their *pecus*, their wealth, before the *pecunia* assumed its later forms of currency. They had also passed through their *bronze* and into their *iron* period; for their language shows that they were already acquainted with the most useful metals as well as with the most valuable grains.

The whole evidence of history points to the seats of earliest civilisation in warm climates, on the banks of the Nile, the Euphrates, the Tigris, the Indus, and the Ganges. The shores of the Mediterranean succeeded in later centuries to their inheritance, and were the seats of long-enduring empires, whose intellectual bequests are the life of all later civilisation. But trans-Alpine Europe, which is now yielding up to us the records of its prehistoric ages, is entirely of modern growth so far as its historic civilisation is concerned, and wherever it extends towards the northern verge of the temperate zone it is even now in its infancy. Here, then, we trace our way back to the first progressive efforts of reason, and find man primeval, in a state of nature, in the midst of the abundance pertaining to a genial and fertile climate, which rather stimulates his æsthetic faculty than enforces him by any rigorous necessity to cultivate the arts for the purposes of clothing and building. Thus employing his intellectual leisure, he begins that progressive elevation which is as consistent with his natural endowments as a rational being as it is foreign to the instincts of all other animals. He increases and multiplies, spreads abroad over the face of the earth, clears its forests, drains its swamps, makes its rivers and seas his highways, and its valleys and plains his fertile fields and pasture-grounds. Cities rise, with all the fostering influences of accumulated wealth and settled leisure, and with all the stimulating influences of acquired tastes and luxurious desires. The rude pictorial art—not ruder on the graven ivory of the troglodytes of the Madelaine cave than on many a hieroglyphic drawing of the catacombs and temples of Egypt—employed in picture-writing, passes by a natural and inevitable transition from the literal representations of objects to the symbolic suggestion of ideas, to a word-alphabet, and then to pure phonetic signs. The whole process is manifest from the very infancy of Egyptian picture-writing, as crude as that with which the Indian savage still records his deeds of arms on his buffalo-robe, or carves the honours of the buried warrior on his grave-post. Letters lie at the foundation of all high and enduring civilisation, yet we can thus trace them back to their infantile origin; and so onward in their slow transformations, as in the mingled pictorial and phonetic writing of the Rosetta stone hieroglyphics of the age of the Ptolemies. Through Phœnician, Greek, and Roman modifications, they have come down to us as the arbitrary symbols of sounds which the voice combines into articulate speech.

And as it is with letters so it is with man's *arts*,—his drawing, carving, sculpture, architecture, weaving, pottery, metallurgy; and so with his *science*,—his astrology, astronomy, geometry, alchemy, and all else. The beginnings of all of them lie within our reach. We can trace back the measurements of solar time to the crudest beginnings of more than one ancient nation, with a year of 360 days. This, corrected to the definite approximation to the true solar year of a period of 365 days, became the vague year of the Egyptians, with the great Sothiac cycle of 1460 years, clearly pointing to a system of chronology which could not have been perpetuated through many centuries without conflicting with the most obvious astronomical phenomena as well as with the recurring seasons of the year.

Man is, after all, according to the boldest speculations of the geologist, among the most modern of living creatures. If indeed the theory of evolution from lower forms of animal life is accepted as the true history of his origin, time may well be prolonged through unnumbered ages to admit of the process which is to develop the irrational brute into man. But regarding him still as a being called into existence as the lord of creation, endowed with reason, the demonstration of a prolonged existence of the race, with all its known varieties, its diversities of language, and its wide geographical distribution under conditions so diverse, tends to remove greater difficulties than it creates. No essential doctrine, or principle in morals, is involved in the acceptance or rejection of any term of duration for the human race; and the idea of its unity, which for a time was scornfully rejected from the creed of the ethnologist, is now advocated by the evolutionist as alone consistent with the physical, mental, and moral characteristics common to savage and civilised man, whether we study him amid the traces of palæolithic osteology and arts, or among the most diverse races of living men.

The process of research and inductive reasoning thus applied by the archæologist to the traces of primitive art and the dawn of civilisation, is no less applicable to all periods. The songs and legends of the peasantry, the half-obliterated traces of ancient manners, the fragments of older languages, the relics of obsolete art, are all parts of what has been fitly styled "unwritten history," and furnish the means of recovering many records of past periods which must remain for ever a blank to those who will recognise none but written or monumental evidence.

Proceeding to the investigation of this later and, in most of the higher requirements of history, this more important branch of historical evidence, the archæologist has still his own special departments of investigation. Tracing the various alphabets in their gradual development through Phœnician, Greek, Roman, and other sources, and the changing forms which followed under the influences of Byzantine and mediæval art, a complete system of palæography has been deduced, calculated to prove an important auxiliary in the investigation of monumental and written records. Palæography has its own rules of criticism, supplying an element of chronological classification altogether independent of style in works of art, or of internal evidence in graven or written inscriptions, and a test of genuineness often invaluable to the historian.

Architecture, sculpture, and pottery have each their historical value, their periods of pure and mixed art, their successions of style, and their traces of borrowed forms and ornamentation, suggestive of Indian, Assyrian, Egyptian, Phœnician, Punic, Greek, Etruscan, Roman, Arabian, Byzantine, Norman, or Renaissance influences. Subordinate to those are the pictorial arts combined with sculpture and pottery, from earliest Egyptian, Greek, or Etruscan art to the frescoes and paintings of mediæval centuries; and the rise of the art of the engraver, traceable through ancient chasing on metals, mediæval niello-work, graven sepulchral brasses, and so on to the wood blocks, whence at length the art of printing with movable types originated. And as in the Old World so in the New, the progress of man is traceable from rudest arts of stone and copper to the bronze period of Mexico and Peru, where also architecture, sculpture, and pottery preserve for us invaluable materials for the elucidation of that prehistoric time which only came to an end there in the year 1492 A.D.

Heraldry is another element by means of which archæology provides trustworthy canons of criticism in relation to written and unwritten mediæval records. The seals and matrices, sepulchral sculptures, and engraved brasses, along with an extensive class of the decorations of ecclesiastical and domestic architecture, all supply evidence whereby names and dates, with confirmatory collateral evidence of various kinds, are frequently recoverable. From the same sources also the changing costume of successive periods can be traced, and thus a new light be thrown on the manners and customs of past ages. The enthusiastic devotee is indeed apt at times to attach an undue importance to such auxiliary branches of study; but it is a still greater excess to pronounce them valueless, and to reject the useful aids they are capable of affording.

No less important are the illustrations of history, and the guides in the right course of research, which numismatics supplies, both in relation to early and mediæval times. But on this and other sections into which the study of antiquities is divided, the requisite information will be found under the several heads of research. On many of those points the historian and the archæologist necessarily occupy the same field; and indeed, when that primitive period wherein archæology deals with the whole elements of our knowledge regarding it, as a branch of inductive science, and not of critical history, is past, the student of antiquities becomes to a great extent the pioneer of the historian. He deals with the raw materials: the charters, deeds, wills, grants of land, of privileges or immunities, the royal, monastic, and baronial accounts of expenditure, and the like trustworthy documents; by means of their palæography, seals, illuminations, and other evidence, he fixes their dates, traces out the genealogical relationships of their authors, and in various ways prepares and sifts the evidence which is to be employed anew by the historian in revivifying the past. Architecture and all departments of the fine arts, in like manner, supply much evidence which, when investigated and systematised by a similar process, adds valuable materials to the stock of the historian, and furnishes new sources for the illumination of past ages. Such is a sketch of the comprehensive investigations embraced under the name of archæology, which, carried on by many independent labourers, and in widely varied fields of research, have contributed important chapters of human history, and revivified ages long buried in oblivion, or at best but dimly seen through distorting media of myth and fable. (D. W.)

CLASSICAL ARCHÆOLOGY.

The province of classical archæology is to investigate and determine the results of artistic activity among the Greeks and Romans, so far as that activity manifested itself in works of form and substance as opposed to the artistic expression of thought by unsubstantial means, as in the case of poetry or music. It ranges from the Greek temple as the highest form of artistic expression in this sense to the other extreme of the simplest object shaped for a purpose by human hands. A stone, rudely hewn with some design, an artificial tumulus, and common clay utensil, each represent, in a humble fashion, a thought artistically expressed in substance, and each reflect more or less accurately the artistic spirit of the time at which they were made. It ranges also from the earliest examples of workmanship down through the historical periods of development and decline. So far classical archæology may properly be called a section of the general history of art. It owes its independent position entirely to the peculiar circumstances under which its investigations are conducted. For example, when called upon to determine the date of an inscription from the forms and disposition of its letters, which, as works of art, must reflect the taste of the period in which they were incised, it has to bring to bear on the question a knowledge of palæographical eccentricities. Or when the date of a coin has to be fixed, the standard on which it has been struck and the historical circumstances connected with it must be taken into consideration. Such, at least, is the practice of journals and societies devoted to classical archæology. On the other hand, recent writers desire to confine these collateral inquiries to within the narrowest possible limits. They have agreed to dismiss altogether mythological researches, which in Gerhard's time formed one of the principal occupations of archæologists. Most of them consent to epigraphy being classed under philology. With regard to numismatics, however, opinions are still divided as to whether it should be included under archæology, on the ground of the immense importance of coins as monuments of art, or whether, on account of their historical value, the study of them should be classed under philology. A similar question has been raised regarding topography. (See Conze, *Ueber die Bedeutung der classischen Archäologie*, Wien, 1869; Preller, *Ausgewählte Aufsätze*, pp. 384–425, *über die wissenschaftliche Behandlung der Archäologie;* Stark, in the *Philologus*, xiv p. 645, and xvi. p. 85.)

The material for the study of classical art consists of literary records and actual remains, among the former being included, though from another point of view belonging to the latter class, the inscriptions which have been found incised on sculptures, or more frequently on the bases left behind in Greece as worthless by the plundering Romans. The literary records have been collected by Overbeck, *Antike Schriftquellen*, Leipzig, 1868, and the inscriptions alone more recently by Hirschfeld, *Tituli Statuariorum Sculptorumque*, Berlin, 1871. The actual remains may be arranged under the three classes of architecture, sculpture, and painting, with the first mentioned being included the industrial arts, in which principles of construction were applied, *e.g.*, the furniture of temples and dwelling-houses, as opposed to the imitative arts. In the case of architecture proper, owing to the immovable nature of its monuments, dependence has to be placed on the trustworthiness of drawings and descriptions made on the spot by travellers. Sculpture, on the other hand, being comparatively easy of transport in all cases, and having been for centuries the object of extraordinary avidity among cultivated people, is now fairly represented in all its important stages in any one of the principal museums of Europe. Painting, in its highest sphere, may be said to exist only in the record supplied by the occasional statements of ancient writers. But these statements embody the opinions of those whose judgment in regard to sculpture we have the means of verifying, and unless there were reason to suppose that persons accustomed to exact the greatest refinement in sculpture were lightly gratified in the matter of painting, their desultory remarks will furnish some idea of the ancient manner for which the remains of wall painting at Pompeii will serve as a foundation, though apparently executed by workmen rather than artists, and that at a time when the art had sunk to its lowest ebb. The skill in drawing attained by ordinary workmen is amply displayed in the painted vases.

Without attempting to subject the history of art to systematic study, the Greeks and Romans nevertheless devoted much attention to special branches of it. The fruits of their labours have in great part perished; but from what remains, and from the notices of what is lost, it appears that their researches took the direction either of explaining the principles of art, and especially those of architecture, or of collecting facts concerning artists and their works, or of describing the works of art which existed in this or that place, as in a catalogue. Of the first class of works we have lost all—and they were many—except Vitruvius. Of the second the losses are known to have been great, and, poor though the substitute for them undoubtedly is, we are still fortunate in possessing such in the notices collected by Pliny in his *Historia Naturalis.* We have besides a long series of epigrams, for which there was no dearth of point, in the works of well-known artists. For a similar purpose the rhetoricians chose frequently to draw comparisons from or to describe works of art; but owing to the object they had in view, they have left little that is of much practical good for the history of ancient art.

The same applies to the epigrammatists. (See O. Benndorf, *De Anthologiæ Græcæ Epigrammatis quæ ad artes spectant*, Bonn, 1862.) With regard to Pliny, it seems that, though himself destitute of all critical faculty in matters of art, he frequently drew his notices from excellent authorities. The third class of ancient writers on works of art were the Periegetæ, of whom only Pausanias survives (A.D. 160–180), his Ἑλλάδος Περιήγησις, in ten books, being of the highest value from an antiquarian point of view. For the criticism of art it brings little benefit.

As to the fate of works of art during the early centuries of Christianity, the first record we possess is that of Nicetas Acominatus, of Chonæ in Phrygia, who died in 1216 (*Narratio de Statuis Antiquis quas Franci post captam, anno* 1204, *Constantinopolim destruxerunt*, Leipzig, 1830). In 1460 we have an anonymous description of Athens (Τὰ θέατρα καὶ διδασκαλεῖα τῶν Ἀθηνῶν, see L. Ross, *Archäologische Aufsätze*, i. p. 245), from which may be gathered a tolerable idea of the deep ignorance of the times. In Rome the rule was to destroy as far as possible all ancient sculptures, except such as were in some way identified with Christianity. The reaction against this manner of proceeding at first took the form of collecting ancient sarcophagi for the modern purposes of burying-grounds. By the 15th and 16th centuries this taste had developed into an enthusiasm, which spread even into the south of Germany, for the possession of ancient sculptures as models for the study of artists. In the beginning of the 17th century this enthusiasm gave way to a habit of viewing ancient works of art only as so many illustrations of ancient beliefs and modes of life, a habit in which the French and the Dutch were distinguished, and of which the results are nowhere more apparent than in Montfaucon's *L'Antiquité expliquée et representée en figures*, Paris, 1722, with its uncritical text and inaccurate engravings. The taste of the times preferred literature to art, and accordingly the collection of ancient monuments, adapted to the illustration of classical writers, and especially the poets, was assiduously followed. A typical example of the one-sidedness of this tendency is to be seen in Spence's *Polymetis, or an Enquiry concerning the Agreement between the Works of the Roman Poets and the Remains of the Ancient Artists*, London, 1755, fol. A really valuable work of the period, however, was the collection of passages in the ancient writers bearing upon artists, entitled *Catalogus Artificum*, by Fr. Junius (Francois Dujon), which retained the position of a standard work until supplanted by Sillig's *Catalogus Artificum*, Dresden, 1827, which in turn held its ground until the appearance of H. Brunn's *Geschichte der Griechischen Künstler*, 2 vols., 1853 and 1859.

Up to the middle of the 17th century no steps had been taken to visit and explore the monuments of Greece. The pioneers in this work were J. Spon, a physician of Lyons, and George Wheler, an Englishman, who travelled together in 1675–76 through Italy, Dalmatia, and Greece, and published each a separate account of their journey (J. Spon, *Voyage d'Italie, de Dalmatia, de Grèce, et du Levant*, Lyon, 1678; G. Wheler, *Journey into Greece*, London, 1682). In the year previous to their arrival in Greece, the Marquis de Nointel, French ambassador at the Porte, had paid a short visit to Athens, and set Carrey, a French artist, to work to draw the sculptures of the Parthenon and some of the buildings of the town. These drawings are now in the Bibliothèque at Paris, and though mostly sketched hurriedly, or from an awkward point of view, form an invaluable record of the sculptures of the Parthenon, destroyed shortly after (1687) by the bombardment of Athens by the Venetians under Morosini.

The discovery of Herculaneum in 1720 and of Pompeii in 1748 opened a new era in the history of archæology. The antiquarian spirit gave way to an historical and scientific method, of which Count Caylus (*Recueil d'Antiquités*, Paris, 1752–54, 7 vols.) may be regarded as the forerunner, and Winckelmann (1717–1768) as the actual founder. The fame of the latter rests on his two great

Greek Amphora, Late Style

Etruscan Sarcophagus. Late Style

works—(1.) the *Geschichte der Kunst des Alterthums*, Dresden, 1764, and with additions, 1767; and (2.) *Monumenti Antichi Inediti*, Rome, 1767, 2 vols. fol. It was in the former that he elaborated his two theories—first, that the quality of artistic productions is always in harmony with the character and the events of the times; and, secondly, that ideal beauty originates in the union of individually-beautiful forms observed singly and apart in nature. Whatever may be said of the narrowness or want of precision in his artistic and philosophical speculations, it still stands to his great praise and renown that he was the first to undertake a vigorous examination of the terms, beauty and ideal, in their relation to nature. It was through his influence that the history of ancient art was introduced into the course of academical study by Heyne, that Goethe, Lessing, and Herder turned each the force of his consummate genius to ancient art, and that the publication of ancient monuments with critical apparatus received a new impulse. Among the immediate disciples of Winckelmann were Zoëga (1755–1809), Visconti (1751–1807), and Millin. After Winckelmann, the next history of ancient art that appeared was Meyer's *Geschichte der bildenden Künste bei den Griechen und Römern*, Dresden, 1824–36, 3 vols.; contemporary with which the only important contributions to the subject were those of C. A. Böttiger and Hirt.

While German activity was engaged on theories of art based principally on the monuments existing in Italy, a practical view of the subject was taken in England, the first issue of which was that Stuart and Revett went to Athens in 1751, and spent nearly three years in exploring and drawing its remains, the result appearing in the work *Antiquities of Athens*, vol. i., 1762; vol. ii., 1787; vol. iii., 1794; and vol. iv., 1816. The task begun by them was taken up by the Society of Dilettanti (founded 1734), whose first expedition under Dr Chandler, Revett, and Pars, an artist, in Greece and Asia Minor, was productive of two works—(1.) *Ionian Antiquities* (published in 1769, and again, largely increased by the researches of William Gell, in 1797); and (2.) *Unedited Antiquities of Attica*, 1817. At this time, Lord Elgin, then British ambassador at the Porte, had a large force of workmen employed in removing the sculptures of the Acropolis of Athens, which, after years of tossing hither and thither in London, at last, in 1816, found a resting-place in the British Museum, of which they continue to form the greatest ornament. In 1811-12 a number of English, German, and Danish travellers (Cockerell, Forster, Stackelberg, Haller, Linckh, and Brönstedt) undertook the exploration of Ægina at their own expense, and were fortunate in the recovery of the sculptures of the temple of Athene, now in Munich.

In 1812 the temple of Apollo Epicurius at Phigalia was explored by Cockerell, its sculptured frieze recovered and obtained for the British Museum, and its architecture elucidated in the still unapproached work of Cockerell, *The Temples of Jupiter at Ægina, and of Apollo at Bassæ, near Phigalia*, 1860. Among the other researches undertaken about this period were—(1.) The French Expédition scientifique de la Morée, the chief result of which was the discovery of some fragments of the metopes of the temple of Zeus at Olympia. (2.) The excavations on the Acropolis of Athens, directed by L. Ross, in 1834–36. (3.) The excavations of Angell and Harris on the Acropolis of Selinus in Sicily in 1822–23, resulting in the recovery of three sculptured metopes of a very archaic style, and fragments of three more metopes (Samuel Angell and Thomas Harris, *Sculptured Metopes of the Ancient City of Selinus in Sicily*, London, 1826, fol.) (4.) The exploration of the same site by the duke of Serradifalco (*L'Antichità della Sicilia*, Palermo, 1834), with the further gain of four metopes sculptured in a more advanced style (O. Benndorf, *Die Metopen von Selinunt*, Berlin, 1873). These sculptures are in the Museum of Palermo. (5.) The extensive operations in Etruria from 1828 onwards, the enormous spoils of which, consisting of painted vases, bronzes, &c., led to the foundation of the Instituto di Corrispondenza Archeologica at Rome, which has continued uninterruptedly, with the support of the Prussian Government, its publication of *Annali*, *Bullettino*, and *Monumenti*, furnishing a complete repertory of archæological research up to the present day. (6.) The removal of the sculptures on the Acropolis of Xanthos (Fellows, *Asia Minor*, 1839, and *Travels in Lycia*, 1841), and the remains of the Mausoleum at Halicarnassus (Newton, *History of Discoveries*, &c., 1862, and *Travels in the Levant*, 1865), have been the principal additions of that class to our national collection, which, however, has been immensely enriched in objects of minor artistic importance, but of great archæological interest, from excavations in Greece, at Camirus and Jalyssus in Rhodes, in Sicily, in the Cyrenaica, and in Cyprus. In the Crimea the excavations of the Russian Government have brought very important treasures to light (*Antiquités du Bosphore Cimmérien conserves au Musée Impérial de l'Ermitage*, Petersburg, 1854; *Comptes Rendus de la Commission Archéologique*, from 1859).

The rapid and vast accumulation of new material after the time of Winckelmann required a new informing spirit. The first to assume this function was Thiersch, in three articles, "Ueber die Epochen der bildenden Kunst unter den Griechen," 1816, 1819, 1825, in which he endeavoured to prove the influence of the Egyptians and Phœnicians on early Greek art. Against him appeared K. O. Müller, denying altogether an exoteric influence, and comparing the development of Greek art to the organic development of plants, its various periods being coincident with the marked periods of political history. These opinions he propounded first in a series of articles (*Kleine Schriften*, ii. pp. 315–398), and afterwards in the celebrated *Handbuch der Archäologie* (1830; 2d ed. 1835; 3d ed. 1848, with additions by Welcker), which, with the plates by Oesterley (*Denkmäler der alten Kunst*), is still unsurpassed in its kind. Müller's view has continued to be adopted by all the leading archæologists since his time, among whom may be here mentioned Gerhard, Welcker, Otto Jahn, and the historians of art generally, Schnaase, Kugler, and Lübke. Besides the *Handbuch*, however, with its additional volume of *Denkmäler* by Wieseler, it is necessary, for the most recent information, to consult Brunn's *Geschichte der Griechischen Künstler*, 2 vols.; Overbeck's *Geschichte der Griechischen Plastik*, 2d. ed., 1872; Friederichs's *Bausteine*, Berlin, 1868; *Kleine Kunst und Industrie*, Berlin, 1871, by the same author; G. Semper, *Der Stil in den technischen und tektonischen Künsten*, Munich, 1860–63; C. Bötticher, *Die Tektonik der Hellenen*, 2d. ed., Berlin, 1872–3; Helbig's *Wandgemälde Campaniens*, 1868, vol ii. of Schnaase's *Geschichte der bildenden Kunste*; Helbig's *Untersuchungen über die Wandgemälde Campaniens*, 1873, the publications of the Instituto di Corrispondenza Archeologica of Rome, and the *Archäologische Zeitung* of Berlin. It is not assumed that this list exhausts the number of books that may be consulted with profit, but it is hoped that no essentially important work has been overlooked.

First Period.

The oldest remains of workmanship in Greece, if we except the series of stone implements discovered within the last few years in various localities, are the ruined walls of Tiryns and several other ancient citadels, the stupendous masonry of which, together with the primitive manner of construction by means of unhewn polygonal blocks of

Earliest Greek remains

immense size, led the later Greeks to believe that they had been the work of a mythical race of giants, Cyclopes, and to designate such masonry as Cyclopean. It was further said that these Cyclopes had come from Lycia, between which and Argolis, where the most remarkable of these walls are, there existed (whatever may be the value of this belief) a very frequent intercourse in the heroic times. Pausanias (ii. 25, 8), speaking of the walls of Tiryuth, which still, apparently, present the same aspect as when he saw them, remarks that the smallest of the blocks would be more than a load for a yoke of mules. Again (ix. 36, 5) he compares them with the pyramids of Egypt as regards the difficulty of the task of building and their colossal dimensions. Instead of the unsatisfactory Cyclopes, the Pelasgians, who preceded the Greeks in the occupation of the soil, are now accredited the authors of this primitive masonry, to which accordingly the much-abused term Pelasgic is applied. Pausanias (i. 28, 3) describes the oldest part of the walls of the Acropolis at Athens as the work of Pelasgic settlers there. In what relation of blood this race may have stood to the Greeks who succeeded them cannot be determined, but it is known that the Greeks adopted from them, among other religious beliefs and rites, those of Dodona; and since even this primitive style of masonry commended itself to them for a time, the Pelasgians must be regarded as having in some degree assisted in the artistic progress of their successors. The walls of Mycenæ furnish an example of the fine skill with which the Greeks afterwards employed the Pelasgic construction, the blocks of stone being carefully jointed and hewn on the outer surface, while the interior of the wall is filled up with mortar and small stones. Mycenæ claimed to be one of the very oldest towns of Greece, and its walls may fairly be regarded as the oldest known monument of Greek workmanship. A considerable advance of skill is noticeable in the masonry of the treasure-houses (*thesauri*), or dome-shaped and partly subterraneous buildings, which occur in several districts of Greece, and of which the treasury of Atreus (so named by Pausanias) at Mycenæ is a typical example. It is built of circular courses of evenly hewn and jointed stones, the courses narrowing towards the top, and there held together by a keystone. It is not, however, an instance of vaulting in the true sense. The most remarkable features in the building are—first, the pilasters and tablets of coloured marble, decorated with a peculiar style of ornament, the elements of which are spirals and zigzags; and secondly, the sheets of bronze with which the interior walls were plated. Of the latter little more than the nails have been found with which they were attached. Of the former a number of fragments, some of which are now in the British Museum, have come to light. The disposition, and especially the profusion of ornament which they display, differ strikingly from the simplicity of Greek work as we know it, and have given rise to a theory which is now accepted as proved, that the Greeks at this time must have been strongly influenced by the example of Oriental artists (Schnaase, *Geschichte der bildenden Künsten*, ii., fig. 28, Düsseldorf, 1866). Meantime, it is a fact of the first importance that this building, which Pausanias appears to have had good grounds for naming the treasury of Atreus, and thus assigning it to the heroic age before the time of Homer, furnishes a remarkable illustration of the descriptions of princely palaces given by the poet, according to whom the walls were plated with dazzling bronze, and the cornices, pillars, and doors enriched with work in other metals. When, therefore, a building in the remains of which a complete absence of Greek simplicity and a powerful suggestion of Oriental influence have been unanimously recognised, was found to correspond accurately with the descriptions of Homer, it was both time to inquire whether the frequent notices of works of art in his pages also point in the same direction, and reasonable to assume that his testimony elsewhere in matters of art was equally reliable. From the poet's evidence on the condition of art in his time we gather that the various processes of working in gold, silver, iron, tin, and bronze were known, with the exception of casting and soldering in the last-mentioned material, and of welding iron. Wood and ivory were carved and jointed, the art of pottery was known, and weaving and embroidery, the foundation of pictorial art, were practised. We hear of richly-ornamented articles of furniture, armour, and dresses. We read of the τέκτων, χαλκεύς, and σκυτοτόμος. Occasionally the names of particular artists are mentioned, as of Tychius, who made the shield of Ajax (*Iliad*, vii. 222), and of Icmalius, who made Penelope's chair (*Odyssey*, xix. 60). On the other hand, the work of amateurs is often praised, as the couch made by Odysseus (*Odyssey*, xxiii. 189), and the figured garments worked by Andromache and Helena (*Iliad*, iii. 125, and xxii. 441). When the workmanship of an object is of surpassing beauty and the artist unknown, as in the case of the Sidonian crater (*Odyssey*, iv. 617), it is ascribed to the artist god Hephæstus, to whom also the same honour is done when the work, as in the case of the shield of Achilles, was a poetic creation. That Homer should in the same breath speak of an object as Sidonian and the work of a Greek god, is a singular mistake, which would hardly have been committed had the articles imported from the Phœnicians differed in style from articles of the same class produced by native workmen. So far, artistic feeling seems to have been directed exclusively to the decoration of objects of daily use. It had not yet aspired to the production of one object which could rest on its merits as a mere work of art,—as, for example, a statue. We have, indeed (*Iliad*, vi. 301), mention of a statue of Pallas at Troy; but the fact that women are described as placing drapery on its knees is sufficient proof of its having been a mere rude Xoanon, such as we find frequently represented on the painted vases. The same phenomenon occurs in the remains of Assyrian art, among which, with all the wealth of sculpture in relief and of the highest excellence, there are only three or four statues, and those of such exceeding rudeness that we are compelled to suppose that they were intended to be draped like the figure of Pallas just mentioned. We have seen that the ornaments of the treasury of Atreus at Mycenæ pointed clearly to an Oriental origin. It is agreed that the relief of two rampant lions from above the gateway to the citadel of Mycenæ (Müller's *Denkmäler der alten Kunst*), which is the solitary existing instance of Greek sculpture from about Homeric times, is of an Oriental character in the composition, in the flatness of the relief, and in the design of the pillar which stands between the lions. We find further, as was pointed out by Layard (*Nineveh*, Appendix), among the many remains of the inferior arts from Nineveh, illustrations of the references to such matters in Homer, which are admirable in themselves, and are found nowhere else, except occasionally in the oldest Etruscan tombs. Now, as Assyrian art reached its culmination by about the 9th century B.C., we may assume that, contemporary with Homer, it was being practised with great activity. On the testimony of Herodotus we know that Assyrian wares were imported into Greece by the Phœnicians and sold in the heroic times; and, on the testimony of Homer, these same Phœnicians were in the habit of selling costly articles of furniture and dress to the Greeks of his time. Of early Phœnician art, however, we have no authentic remains, nor indeed any proof of its having had an independent existence at any time. We know the Phœnicians mainly as traders, and it is highly probable that in matters of art their

Connection of Greek and Oriental art.

trade lay chiefly between the Assyrians on the one hand and the Greeks on the other. "It was the Phœnicians," says Brunn (*Die Kunst bei Homer*, München, 1868), "who brought from the East to the Greeks an alphabet which they modified and employed for a language peculiar to themselves; and it was the Phœnicians who brought to them from the same quarter an alphabet, so to speak, of art, which they also modified and employed for a language of art equally their own." He proceeds to define this alphabet of art as consisting of a knowledge of the processes of weaving and embroidery, of working in wood, ivory, and the various metals, with the exception of casting in bronze —with which and with sculpture in marble, which he also excludes, commenced the art of statuary, and commenced, therefore, the independence of true Greek art. Besides these processes of working, the Greeks derived from the same source at least some of the decorative patterns which we find in use in later times, though greatly modified. But, above all, they obtained from the Assyrians that manner of sculpture in low flat relief, and in parallel horizontal bands, which they appear to have practised almost exclusively down to the 7th century B.C.,—that is, down to the collapse of the Assyrian empire,—and after that to have retained as one of the charms of their architecture. If, then, an intercourse such as is assumed actually took place in Homer's time between the Greeks and the Assyrians, who were then artistically in a very advanced condition, it will be necessary, before lightly calling the shield of Achilles a poetic dream, as has frequently been done, to see whether the poet may not have had before his mind some manner of a counterpart for it in Assyrian art. We need not suppose that such a shield ever existed. But a poet cannot create out of nothing; and it is clear from his division of the shield into five concentric bands, resembling the large bronze shields found at Cære some years ago in a tomb of very high antiquity, that he had before his mind the customary arrangement of ornaments in works of this kind. Now, on an Assyrian bronze bowl in the British Museum (Layard, plate 61), which exactly resembles in shape and is of about the same size as a boss of a shield, we have a representation of the earth and heavens which very strikingly recalls the decoration of the boss on the shield of Achilles; while in the comparatively few remains of Assyrian sculpture we have cities at war, cities at peace, and many scenes from daily life, which vividly illustrate the Homeric description of the shield (see Brunn *Die Kunst bei Homer*, who deals with the various subjects in detail). It should be observed, however, that though the evidence of the Homeric poems and the remains of Greek art from the Homeric age both point to an Assyrian influence, the Greeks of later times looked rather to Egypt as the land whence their ancestors had experienced their first impulse both in religion and in art. They believed that Dædalus, the first Greek sculptor who knew how to give movement to his figures, and was regarded as the father of Greek sculpture, had learned his art in Egypt. Diodorus of Sicily asserted that Telecles and Theodorus of Samus had visited Egypt, and on their return executed a statue of Apollo in the Egyptian style for a temple in Samus, each having made a half of it, and that apart from the other. Strabo (p. 806) compares the old Greek sculpture with the Egyptian; while Pausanias in several places (ii. 19, 3; iv. 32, 1) speaks of Egyptian statues in Greek temples, or (i. 42, 3; vii. 5, 5) of statues resembling the Egyptian in style. According to another theory, the influence of Egypt on Greek art, though admitted, is relegated to the time of Psammetichus, in whose service it is known many Greek mercenaries were employed, and through whose inclination towards the Greeks an active intercourse sprang up between the two countries. Among the Greeks who visited Egypt at that time were Thales, Cleobulus, Solon, and Pythagoras.

Remains in Asia Minor. Of the connection which is assumed to have existed between the earliest monuments of Greek art and the contemporary art of Assyria, evidence is cited from remains of undoubtedly early workmanship in the countries of Asia Minor, Lycia, Lydia, and Phrygia, of which the two latter were intimately associated with the oldest traditions and religious beliefs of Greece. The peculiar feature of Lycian art is its tombs cut in the rock, of which the oldest class are direct imitations of wooden structures such as we may conceive the primitive temples of an Oriental race to have been. In Phrygia we have another class of rock-cut tombs of very remote antiquity, of which that of Midas (Semper, *Der Stil*, i. p. 429) is the best preserved example. Here the style of decoration is obviously derived from Assyrian tapestry. In Lydia we have tombs again, but they are in the form of immense tumuli,—as, for instance, that of Alyattes near Sardis, which astonished Herodotus by its size, being 1300 feet in diameter at the base, and over 250 feet high. Similar tumuli occur among the old Chaldeans.

Progress of Architecture. With the immigration of the Dorian race commenced the development of an independent style of architecture in Greece, the first step apparently being the invention of a house supported by columns as the design for a temple From the description given by Pausanias (v. 16) of one of these early Doric temples—that of Hera at Olympia, erected shortly after the Dorian immigration—we gather that it had the form of a temple *in antis*, surrounded by columns, and with not only a *pronaos* led into by two columns, but also a similar chamber at the back. One of the two columns of this latter chamber was of wood, apparently a reminiscence of a former style of construction in that material. About the same time originated also, it is supposed, the Ionic order, which though presenting a certain Asiatic richness of ornament strongly opposed to the severe simplicity of the Doric, was still a pure Greek invention. The fact of it having first appeared among the Greeks of Asia Minor is enough to account for its admission of a greater softness and flow of lines than was admitted in the Doric. With the new movement in architecture a fresh impetus was given to the art of sculpture. **Sculpture.** At first the reports sound somewhat fabulous,—as, for example, that in which Butades the Corinthian potter is described as having hit on the idea of modelling a face in clay and baking it along with his vases. Butades himself, however, is an historical person, and Corinth is known to have been a flourishing seat of potters and other artists as early as the time of the tyrant Cypselus (650 B.C.), through whose oppression it is said the artists, Eucheir, Diopus, and Eugrammus emigrated to Etruria, which afterwards became celebrated for its sculptures in terra-cotta. At the commission of Cypselus, or of his successor Periander, a colossal statue of Jupiter was executed at Corinth, and dedicated at Olympia. But the most remarkable specimen of early sculpture, presumably Corinthian, was the chest in which the infant Cypselus was concealed, and of which a detailed description is given by Pausanias (v. 17, 5, fol.) The chest, itself of cedar, was ornamented with a wealth of figures in gold and ivory, arranged in parallel horizontal bands, and representing heroic legends and scenes from daily life, the names of the individual figures being inscribed *boustrophedon*, that is, in the manner characteristic of early times, and in what Pausanias calls very ancient letters. The François vase in Florence (*Monumenti dell' Instituto di Corrispondenza Archeologica*, vol. iv. pls. 54–58) gives a tolerable notion of what the composition must have been. Artistic activity was not then confined to Corinth. A school of sculpture in marble existed in Chius as early as 660 B.C., and there also Glaucus is said to have discovered the art of welding iron (692 B.C.), the substitute for which had previously been nails. At this period we have frequent mention of splendid metal utensils, as, for instance, the enormous cauldron (Herodotus, iv. 152), with projecting gryphons' heads and a support formed of kneeling figures, seven ells in height. As the oldest example of sculpture in bronze which he had seen, Pausanias (iii. 17, 6) describes a statue of Jupiter at Sparta, the work of Clearchus of Rhegium, whom some called a pupil of Dædalus. It was made of plates of bronze, beaten out to express the whole figure, and then fastened together with fine nails, the arts of soldering and of casting being still unknown. Of sculpture in this manner we possess only one example, the bronze bust found at Polledrara, near Vulci, and now in the British Museum. Throughout this early period the statues or images of deities seem to have retained their helpless primitive form, feelings of piety and gratitude being apparently expressed rather in gifts of metal utensils to the temples than in statues of the gods as in later times. No such statues exist now, but we have sufficient evidence of their want of artistic merit in the numerous representations of them which occur on the painted vases of a later period, when the sanctity of a spot is frequently indicated by such a figure. Apparently to this early and as yet barely historical period belongs a

FIG. 1.—Fictile vase. Brit. Mus. From Athens. Design in black, on drab ground.

class of painted vases decorated with figures of animals and flowers arranged in parallel horizontal bands, and therefore both in the choice and disposition of the decorations presenting a marked instance of Assyrian influence. From their shape it appears that many of these vases were made to hold precious liquids, such as perfumes; and it is very probable that they were imported from the East with those perfumes, the names of which in the Greek language have an obvious Oriental origin. A considerable advance is noticeable in a second class of these vases, in which the human figure is introduced as the principal subject in the decoration, the designs being in general chosen from the heroic legends of Greece. These vases still retain the shape of the former class, the method of disposition in parallel bands, and the choice of subordinate ornaments. The names of the heroes are frequently written beside them, and sometimes the artist adds his own name. The alphabet in which these names are written is the old Corinthian, and hence the vases in question are also styled Corinthian. As to their date, it is agreed that they cannot be later than 620 B.C. With the introduction of the human figure as the subject most worthy of artistic rendering, commenced in vase painting also the independence of the potter's art in Greece (Brunn, *Probleme in der Geschichte der Vasenmalerei*).

Second Period.

From the date of the earliest historical notices of sculptors, backward to that usually assigned to the Homeric poems, there is an interval of several centuries, during which it would at first sight appear that the art of sculpture had made no sensible advance, if indeed it had not declined. This being improbable, an explanation must be sought for, either with Ulrichs (*Die Anfänge der Griechischen Künstlergeschichte*, Würzburg, 1871) in the confusion which seems to reign among the dates of the earliest sculptors, or with Brunn (*Die Kunst bei Homer*) in the theory that the art of sculpture in Greece during that interval was, like the contemporary art of Assyria, strictly confined to working in relief, and that in this direction it may well have made steady progress, though particular artists are not singled out for praise. It is with sculpture in the round, and with some particular invention, as that of welding iron or casting bronze, or with some new technical procedure, as the working of marble, that the first records of artists begin. With regard to the confusion in the dates of these records, it is true that in ancient times the artistic faculty was handed down in certain families, among whom there was also a partiality for certain names. But to assume on the strength of this, as Ulrichs does, that later writers, finding a recurrence of the same name, generally identified it with the most distinguished and hence probably the latest of the artists who bore it, is a means of peopling an apparent void which ought to be supported with better evidence than that which Brunn has controverted at almost every point. For example, in treating of Theodorus of Samus, of whom it is said that he invented the process of casting in bronze, and supposed that he was a contemporary of Polycrates, Ulrichs argues that there must have been two artists of that name (and suggests that there may have been several), because the one who invented bronze-casting must have lived before 576 B.C., previous to which date this art may be inferred to have been known from the remark of Herodotus (v. 82), that the Epidaurians were ordered by an oracle to obtain figures of Damia and Auxesia, not χαλκοῦ ἢ λίθου, but ξύλου. Why χαλκοῦ should not refer to hammered as well as to cast bronze, Brunn is unable to see. Again, it was Theodorus of Samus who built the substructure of the temple of Diana at Ephesus, and Ulrichs is at a loss to conceive how the people of that town could have remained till 576 B.C. without a temple worthy of their goddess. That the previous temple was unworthy of Diana cannot be proved by us, who are ignorant of the feelings of the Greeks in these matters, and who are aware that Jupiter himself had not even in his favourite Olympia a great temple till 456 B.C.

The view taken by Brunn is, as has been said, that until the invention of casting in bronze the Greek sculptors continued to work in relief except when images were required for the purposes of worship, and that in these cases, whether the figure was of wood, stone, or bronze, the rude helpless form of ancient times was preserved. Stimulated, it may be supposed, by the achievements of the newly-invented art, sculptors now began to look to the possibility of producing in marble also a resemblance to the human figure in its substantial roundness. The scene of the first success in this direction was Chius, where a family which for three generations (Melas, Micciades, and Archermus) had been celebrated for its workers in marble, was at this time represented by the brothers Bupalus and Athenis. Works from their hands were to be seen in their native place, in Delus, Iasus, and Smyrna, and consisted, so far as we know, of draped figures of goddesses, with the one memorable exception of a statue by Bupalus intended as a caricature of the poet Hipponax, which was set up in Clazomenæ. The poet took his revenge by circulating some verses which stung the sculptor so severely as to drive him to suicide by hanging. The school of Chius had a rival in that of Magnesia on the Mæander, at the head of which was Bathycles, whose fame is associated with the reliefs and figures on the colossal throne of Apollo at Amyclæ (Pausanias, iii. 18, 9; Overbeck, *Gesch. d. Griech. Plastik*, i. p. 86). He and a number of his pupils or assistants had been purposely invited to the task, and what they accomplished was probably the best that could then be done, however short of the standard of later times it may have fallen in the eyes of Pausanias. One noticeable fact is, that after completing their work, they left behind portraits of themselves, and this, in connection with the portrait of Hipponax, may serve to show that sculptors had already begun to direct their attention to the individual features of the human face. As to the date of Bathycles, Pausanias was uncertain and modern critics are divided, some supposing him to have left Magnesia before its destruction, 636 B.C., others on the occasion of its capture by the Persians, 546 B.C. In favour of the latter date is the statement (Pausanias, iii. 10, 8) that the gold received from Crœsus (563–549 B.C.) by the Lacedæmonians was made a gift of by them for the decoration of the figure of Apollo at Amyclæ.

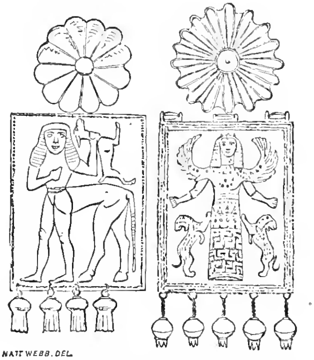
The new phase of art thus entered on, according to tradition, by the Ionians, was now taken up vigorously by the Doric sculptors, among whom the first to attain distinction were Dipœnus and Scyllis, natives of Crete, and members of the ancient guild of sculptors there, which took its name from the mythic Dædalus. Leaving Crete, they settled in Sicyon, probably on the invitation of the tyrant Clisthenes, and were there commissioned to execute at the public cost a group of statues of deities. Their work was, however, interrupted by a disagreement which ended in the artists having to leave the town. They established themselves in Ætolia, and were allowed to remain there until, a plague having fallen on Sicyon, the oracle traced it to the wrath of the gods at seeing their statues incomplete. Dipœnus and Scyllis were recalled, and finished their work at a greatly increased price, from which it may be inferred, perhaps, that the original dispute lay in the matter of payment. Among the many sculptures which they executed in Sicyon and other Greek towns, as Cleonæ, Argus, Tiryns, and Ambracia, some, it is said, were of wood and ivory, a combination of material which may be regarded as having suggested the chryselephantine sculpture of later times (Pliny, xxxvi. 4, 9, 14; Pausanias, ii. 15, 1; 22, 5; Brunn, *Gesch. d. Griech. Künstler*, i. p. 43). For determining their date, we have a passage of Pliny in which he says, "Primi omnium inclaruerunt marmore sculpendo;" adding, "Before Cyrus ascended the throne of Persia, about 576 B.C." From their school proceeded Doryclidas and Dontas, who executed several figures and groups of deities in cedar and gold at Olympia for the Heræum and the treasuries of the Epidaurians and Megaræans; Clearchus of Rhegium, who worked in bronze; and Tectæus and Angelion, from whom Callon, the celebrated Æginetan sculptor, learned his craft. As a work of Tectæus and Angelion, Pausanias (ii. 32, 5; ix. 35, 3) mentions a figure of Apollo at Delus, representing the god in a rigid attitude, the upper arms close to the sides and the fore-arms advanced; in his right hand a bow, and in his left a diminutive group of the three Graces. Contemporary with Doryclidas were Smilis of Ægina and Gitiades of Sparta, the former of whom is known to have executed a group of the Horæ, to be placed with a figure of Themis by Doryclidas. From his hand was also a figure of Hera at Samus. Gitiades, who was at once sculptor, architect, and poet, erected the temple of Athene Chalkioikos, and made the figure of the goddess for it. The temple was coated with plates of bronze, on which were reliefs representing scenes from the legends of Hercules and Perseus, and from mythical incidents, among them being the birth of Athene.

School of Sicyon.

Remaining sculptures.

Turning now to the remains of Greek sculpture, which may with more or less certainty be assigned to the period in which the foregoing sculptors were at work, we begin with the three metopes from the oldest of the temples on the Acropolis of Selinus, in Sicily, which up to now have been regarded as furnishing the first authentic, and as yet the clearest, glimpse of that early stage of Greek art when the foreign elements with which it had grown up were being fast eliminated, and the basis laid of a perfectly independent art. It is not within the range of absolute proof, though it is nearly so, that these metopes belonged to the temple erected by the Selinuntians soon after their settlement as colonists, 651 B.C., or, as others prefer, 628 (Benndorf, *Die Metopen von Selinunt.*) They are sculptured in tufa, and represent —(1), Perseus cutting off the head of Medusa in the presence of Athene; (2), Hercules carrying the Cercopes, bound by the heels, over his shoulders; and (3), a quadriga to the front. In the first two, while the movement proceeds from left to right, the faces are all turned broadly to the front, as if looking to the spectator for applause. It may be that the artist, in thus rendering the grimness and grotesqueness of his subjects with a more staring and vivid effect, had recourse, as is argued, to an innovation on the older manner of representing the figures altogether in profile. This much appears to be certain, from the minute attention which he has devoted to the structure of the knees, the lower parts of the legs, the feet, and the movement of the flesh on the shoulders, that the loss of half a face, entailed by a position in profile, would have grieved him. The drapery is stiff, and studiously arranged in neat folds, which are not always produced by the manner in which it is worn. The hair is disposed in a system of circular locks independent of each other. The proportions of the figures vary considerably, though uniformly characterised by a solidity and heaviness which, from the similar appearance of Doric columns, has been designated as Doric in style. The remains of colour found on these sculptures showed that the ægis of Athene had been sketched on the breast with a reddish brown, and that the same colour had been applied to the ground of the relief. The mæander pattern on the broad fold of Athene's chiton was painted brown, her eyes and eyebrows black. The eyes of the Gorgon were red. The folds of the short chiton worn by Hercules were partially left to be indicated by colour. The muscles are strongly exaggerated, so as to mark the extraordinary physical strength attributed to the heroes of the subject.

Markedly contrasting with these metopes is a marble relief found in Samothrace in 1790, and now in the Louvre, distinguished for the flatness of the figures, which present the appearance of sections of men (Friederichs, *Bausteine*, i. p. 18). The subject, as we learn from the names inscribed by each figure, consists of Agamemnon seated, with the herald Talthybius, and Epeius, the sculptor of the wooden horse, standing behind him. The figures are lean and spare compared with those of Selinus; the folds of the draperies are merely indicated, and appear to have been completed in colour.. The character of the inscriptions, which are in the old Ionian dialect, corresponds with that of the early vases. That this relief cannot be later than 500 B.C. there is no doubt; but all means of determining its date beyond that period fail. Nor is it safe to assign it higher antiquity than the Selinus metopes, on the ground that the figures are all in profile; for a position in profile was by no means an invariable characteristic of early sculpture, as may be seen by reference to fig. 2, in which are given two examples of the ex-



NATT WEBB. DEL.

FIG. 2.—Gold ornaments. Brit. Mus. From Camirus.

tremely early gold ornaments from Camirus in the British Museum, in all of which the figures are placed full to the front (Millingen, *Ancient Unedited Monuments*, ii. pl. 1; Müller, *Denkmäler*, pl. 11, No. 39). From the sacred way leading up to the temple of the Branchidæ at Miletus there are ten marble statues of seated figures now in the British Museum, for which they were obtained by C. T. Newton. Apart from their importance as works of art assignable to this early period, one of them possesses the additional interest of being, as we learn from the inscription on it, a portrait of Chares, a ruler of the neighbouring Teichiousa. The other important examples of sculpture in this period are—(1), the architrave of the temple at Assus, in the Troad (Friederichs, *Bausteine*, i. p. 9); (2), three statues of Apollo—one found at Thera, and now in Athens, the second found at Tenea, and now in Munich, the third in the British Museum, where it is known as the Strangford Apollo. All three stand in the Egyptian manner, resting the weight of the body on both legs. The head sits rigidly on the shoulders, the brow retires, the eyes project and slope inward towards the nose, the lips are close, and the corners of the mouth turned up, producing something like a smile. The hair appears to have been completed with colour (Overbeck, *Gesch. d. Griech. Plastik*, 2d ed., i. fig. 8; Friederichs, *Bausteine*, i. p. 5).

Retrospect. In the course of our notice of this early period certain facts have assumed a prominence which calls for remark. First, it is to be observed that the earliest important schools of sculpture arose in the islands, particularly the islands of Chius, Crete, and Ægina. To what circumstance this was due—whether, for example, to a more active intercourse with Oriental nations—remains unexplained. Next to the islands, the coast of Asia Minor, Magna Græcia, and Sicily were productive of artists. From Crete the new impulse spread to the Peloponnesus, Sicyon, Argus, and Corinth. Secondly, for some reason, the sculptors then mostly worked in pairs. Thirdly, the various materials—bronze, marble, wood and ivory, and gold and ivory—were already in use as in later times. Fourthly, the subjects were—(1), religious and mythological, the epos being the main source; and (2), portraits and statues of successful athletes. Individual artists had at last begun to assert their peculiarities in the conception of the human form. They had begun to give up those general types which bear the same resemblance to a man as does his shadow cast by the sun. In the infancy of art, as in the early morning, the shadows are grotesque. As it advances they improve, till at noon the shadow is lost in the living figure.

School of Sicyon. In the earlier part of our period it is to be observed that the Dorian race still continued to furnish the sculptors of distinction, but the main centres of the art were now in the Peloponnesus instead of the islands. In Sicyon the reputation acquired by Dipœnus and Scyllis was enlarged by Canachus, whose works were spoken of in later times (Cicero, *Brut.* 18, 70) as models of the severe restrained style of the early schools. Statues of deities were his favourite subjects. His material consisted sometimes of wood, as in the figure of Apollo Ismenius at Thebes (Pausanias, ix. 10, 2); sometimes of gold and ivory, as in the figure of Aphrodite at Sicyon (Pausanias, ii. 10, 4); and sometimes of bronze, as in his celebrated statue of Apollo Philesius at Miletus, which is said to have differed from the Apollo at Thebes only in the material. A figure of Apollo answering in general terms to the description of this statue, occurs on certain coins of Miletus and in a remarkable bronze statuette in the British Museum. The attitude of the statuette is stiff, but less pervaded with rigidity than, for example, the Apollo of Tenea. The form, which is quite nude, shows an advance in the study of proportions. The shoulders are still square, but the chest is much fuller, and apparently rendered as if with a reminiscence of its expansion and heaving after athletic exertion. Canachus worked with his brother Aristocles, also a sculptor of high reputation, though of his works all we know is that he took part with Ageladas in the execution of three statues of Muses.

School of Argus. The schools of Argus and Ægina appear to have mostly confined themselves to working in bronze. At the head of the former stood Ageladas, whose principal reputation consists in his having been the instructor of the three great masters, Myron, Polycletus, and Phidias.. Nine of his works are mentioned, including two statues of Zeus, but no description of his style is added, nor is anything regarding it to be inferred from the very diverse manner of his three great pupils. His date falls between 508 and 452 B.C. Argus had also Aristomedon, Glaucus, and Dionysius. **School of Ægina.** In Ægina, where the quality of the bronze (Æginetica aeris temperatura—Pliny, *N. H.*, xxxiv. 2, 5, 10; 8, 19, 75), as well as the artistic excellence of its sculptors, obtained a wide recognition, the first name of importance is that of Callon, a pupil, as has been said, of Tectæus, and Angelion of Sicyon, and a contemporary of Canachus (Pausanias, vii. 18, 10), with whom, in respect of the severity of his style, he has been compared. Of his works we know only of a statue of Athene at Trœzene, and a tripod with a figure of Cora at Amyclæ. Possibly, like his contemporaries, his chief study was that of the finely-developed forms of successful athletes. Greatly beyond him in distinction was Onatas, under whose hands the art of Ægina achieved a reputation which was perhaps only surpassed by that of Athens, and, owing to the political collapse of the island, was never obscured by the inferiority of later schools. His works, which appear to have been mostly of bronze, consisted of large compositions as well as of single statues of gods and heroes. After Onatas we have Anaxagoras, who was employed by the united Greek states to execute the bronze statue of Zeus (15 feet high) for Olympia, in commemoration of the battle of Platææ. On the same occasion the Greeks dedicated two other works of art—a bronze statue of Poseidon ($10\frac{1}{2}$ feet high) for his temple on the Isthmus; and a golden tripod, standing on a bronze support formed of three serpents, for the entrance of the temple at Delphi. In both cases the names of the artists are unrecorded, and probably it will not be wrong to assume that they also were of Ægina. The golden tripod was melted down during the Phocian war; but the support remained *in situ* till the time of Constantine, by whose orders it was removed to Constantinople and placed in the Hippodrome, where it still stands. In 1855 the earth which had accumulated round its base was removed by C. T. Newton, and the names of the Greek states inscribed on it revealed. (Newton, *Travels in the Levant*, ii. p. 25. For the discussion raised on the antiquity of this monument, see Friederichs, *Bausteine*, i. p. 64.)

School of Athens.

In Athens we find in this period Endœus, of whom the scanty records permit us to know almost nothing, and Antenor, the author of a bronze group representing the Tyrannicides, Harmodius and Aristogiton, and erected in the Agora at the foot of the Acropolis. That these figures were executed shortly after the incident which they were intended to commemorate, 550 B.C., is very probable. It is recorded that Xerxes carried them off to Susa in 480 B.C., and that they were restored to Athens by Alexander, or Seleucus, or Antiochus. In the meantime, to repair the loss, two sculptors, Critius and Nesiotes, were employed to replace the group (Pausanias, i. 8, 5; Arrian, *Exped. Alex.* iii. 16, 7; vii. 19, 2; Pliny, xxxiv. 19, 70). Whether the new sculptors were expected to reproduce the composition and the style of the lost figures—as, for example, Onatas did in replacing the figure of the black Demeter at Phigalia—cannot be ascertained. On the other hand, if the two marble statues in the museum of Naples (*Mus. Borbon.*, viii. pls. 7, 8) have been rightly described as copies of the new group, and if it is right to conjecture that the group represented on certain tetradrachms of Athens, and, we may add, on a Panathenaic prize vase in the British Museum, was copied from the older group, on the ground that they were executed about the time when it was recovered from Susa, and therefore probably to commemorate that event, this much at least will be clear, that the composition of both groups was very much the same. On the other hand, the frequency with which statues and groups of statues of various kinds occur on the late tetradrachms of Athens, would equally perhaps require to be explained on the same hypothesis of a restoration, and for this we are not prepared. With respect to the marble statues just mentioned, it is to be observed that the expression of physical energy in them, side by side with a spareness and sinewiness, recalls the characteristic of Myron, and accordingly may be better ascribed to the later artist Critius, than to his predecessor Antenor. As comparable in many respects with one of the statues in Naples we give fig. 3.

School of Magna Græcia.

At Rhegium, in lower Italy, the mantle of Clearchus had fallen on Pythagoras, unless it be true, as is also stated, that he had received his instruction from an otherwise unknown artist, Euchirus of Corinth. A list of the sculptures by Pythagoras (Overbeck, *Antike Schriftquellen*, *s.v.* Pythag.) shows that he worked exclusively in bronze, that his subjects, with the exception of a group of Europa on the bull, in Tarentum, consisted of male figures, and these of a kind in which either a strongly-pronounced

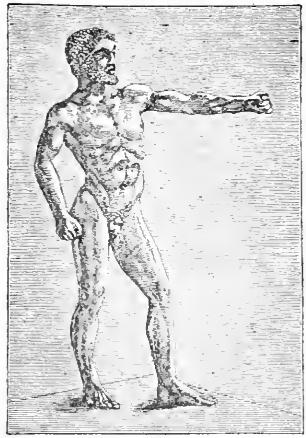


FIG. 3.—Bronze statuette. Brit. Mus. From the collection of the late Mr Woodhouse, Corfu.

muscular action, or a marked capacity for it, must have been expressed. The most famous of them was his statue of Philoctetes at Syracuse, of which the epigram writers declared that the expression of pain in it was such as to move the spectator. To disprove the conjecture that the pain might have been expressed in the face alone, there is a gem in the Berlin Museum (Overbeck, *Gesch. d. Griech. Plastik*, 2d, fig. 42) bearing what there is little doubt is a copy from the statue, from which Philoctetes appears to be suffering contortion through every limb from the wound in his foot as he tries to walk. And this, it may be added, while itself an accurate observation of the effect of such a wound, is an admirable illustration of the talent of Pythagoras for strained, and, what is more, a concentrated straining of, muscular action. From a statement of Pliny, it appears that he was the first to express the veins and sinews of the human form, and from Diogenes Laertius we gather that he was the first to apply rhythmus and symmetry to his figures. The precise meaning of these latter words it is difficult to understand, with nothing better before us than a gem copy of one of the artist's works. It will not, however, be far wrong if we take them to refer to that concentration of the entire action of the body upon one point which has been recognised in the figure of Philoctetes, and which we assume to have been the key to the composition of his groups. This interpretation is further in harmony with the statement of Pliny, seeing that an artistic purpose of this kind could not be carried out without the studious expression of veins and sinews (Brunn, *Gesch. d. Griech. Künstler*, i. p. 132).

Existing sculptures

We have seen how few of the existing monuments can be traced even conjecturally to the artists of this early period, whose names and praises have been handed down to us. Monuments of sculpture there are, manifestly assignable to this period, and some of them worthy of the fame of a great master. But whether the men who executed them were unhonoured in their time, or whether from the insufficiency of our literary records names well known in antiquity may have escaped us, or whether, in fact, the best of these works at least may really have come from the hands of men otherwise well known, remains unexplained. The last-mentioned possibility has been placed in a strong light by Brunn's discussion on the sculptures from the temple of Athene at Ægina, now in Munich. Not that he would trace them directly to the hands of the artists Callon and Onatas of Ægina. What he aims at is to connect the characteristics of the sculptures intimately with the style recorded of these two men, and to leave the rest for conjecture. (*Die Æginetische Giebel-Gruppen, Bayer. Akad.* 1869; and *Ueber das Alter der Æginetischen Bildwerke, Bayer. Akad. d. Wissenschaft,* 1867.)

Sculptures from Ægina.

Of the figures in the western pediment, in which the combat over the dead body of Achilles was represented, only one is lost. From the eastern only five complete figures remain. The subject of it was a combat corresponding in its main features with that of the other pediment. In both the central object of the strife is a fallen hero; in both the goddess Athene appears on the scene. In the one group her figure is entire; in the other only her head remains. In the eastern pediment the only recognisable figure is that of Hercules, and from his presence it has been supposed that the subject of the composition was the combat of that hero and Telamon against Laomedon of Troy. The statues of this pediment are of a bolder and more advanced style than the others, from which it has been inferred that they may have been the work of a younger man, carried away by a new movement in art, while the others may have been the work of an older artist, hardened in the traditions of his school. One thing, however, is plain from the remarkable uniformity which reigns among the figures of both groups, that the artist or artists had hitherto been limited in their study to one type of the human form, and that the nude form of finely-developed athletes. Nowhere is there individuality, but everywhere an excessive carefulness in rendering the forms. The goddess Athene has all the rigidity of the ancient figures intended for a worship which little brooked innovations. The expression on the faces is throughout the same, and the hair is always rendered in one conventional manner. The figures are spare and hard, with as little flesh as possible. In both pediments the scene—a combat over a fallen hero—is intended to stir our sympathy, but entirely fails. There is no straining of muscles, no expression of grief, and no sense of the emergency. We turn from the figures as a whole to the pleasing truthfulness with which the parts are rendered. To give them a greater air of vitality, the lips and eyes of the statues, with such accessories as drapery, sandals, and weapons, were originally coloured blue and red, while many small holes remain to show that part of the armour and ægis on the breast of Athene had been attached in metal, a fact which bears with great importance on the question of the polychromy of ancient statues. With regard to the date of these sculptures, the opinion is, that they could hardly have been executed more than fifty years before the time of Phidias (engraved, Müller, *Denkmäler*, i. pls. 6–8).

Bas-relief.

Among the other existing examples of sculpture assignable to this period we would select as most characteristic—(1.) A marble stele found (1838) in the east of Attica, and now in the Theseum at Athens (Friederichs, *Bausteine* i. p. 26), representing an armed warrior standing in profile, whose name, as appears from the inscription, was Aristion. The sculptor's name, which is also inscribed, was Aristocles. The relief is low and flat, and executed with the greatest care and attention to details, particularly those of the armour. The ground of the relief was painted red and the armour blue, the ornaments on it being picked out with red. Remains of colour were also found on the lips and eyes, while the crest of the helmet appears to have been added in metal. Altogether, Aristion presents a touching picture of the old upright and severe warrior who fought at Marathon. (2.) Another marble stele in Orchomenus, inscribed with the sculptor's name, Anxenor of Naxus, and representing, in low flat relief and in profile, a man of years wearing a mantle, and standing, resting on his staff, holding a beetle towards the dog at his feet (Overbeck, *Gesch. d. Griech. Plastik*, 2d ed., i. fig. 23; Friederichs, *Bausteine*, i. p. 29). (3.) Another marble stele in Naples (*Mus. Borbon.*, xiv. pl. 10; Friederichs, *Bausteine*, i. p. 28), in which the drapery and the forms are still archaic, though showing a considerable advance on the stele of Aristion. (4.) Part of a metope from one of the temples of Selinus in Sicily (Benndorf, *Die Metopen von Selinunt*, pl. 5), representing a goddess, either Athene or Artemis, trampling on an armed male figure, probably a giant, whom she has hurled to the ground. As an example of the archaic manner of relief in this period, this fragment has no equal among existing monuments. The anguish on the face of the giant is depicted with deep feeling; nor is our emotion interrupted by observing that the beard retains its formal trimness, and that the hair remains in graceful ringlets, in no way partaking of the confusion. (5.) Marble relief found on the Acropolis of Athens, and preserved there, representing a female figure, possibly a goddess, stepping into a car (Friederichs, *Bausteine*, i. p. 25). This relief has been supposed, but without sufficient reason, to be a fragment of the frieze of the older pre-Periclean Parthenon. With more justice has it been compared in point of style with (6), the reliefs of the so-called Harpy tomb discovered at Xanthus in Lycia in 1838 by Sir Charles Fellows, and now in the British Museum (Friederichs, *Bausteine*, i. p. 37). (7.) From Xanthus the British Museum possesses another archaic frieze of higher merit, representing a procession of chariots, in which the horses are modelled with extraordinary care (Prachov, *Antiquissima Monumenta Xanthiaca*, 1872). (8.) Marble relief in Thasus representing Apollo, Hermes, and nymphs (Overbeck, *Gesch. d. Griech. Plastik*, 2d ed., i. fig. 28). The figures have an Ionic slimness, such as we found on the architrave from Assus, but with finer proportions than that early work. (9.) Three small reliefs in terra-cotta from Melus (Overbeck, *Gesch. d. Griech. Plastik*, 2d ed., i. figs. 27, 26*a*, and 26*b*), representing Orestes and Electra at the tomb of their father; Perseus mounted on Pegasus and carrying off the head of Medusa; and Sappho,

Fig. 4.—Terra-cotta. Peleus [ΠΕ[Λ]ΕΥΣ] and Thetis. Brit. Mus. From Camirus.

seated, resting from her lyre and looking up towards Alcæus, as at the moment when he said, "You sweet, black-haired, modest Sappho, I have something to say to you." A fourth relief of this style is given in fig. 4.

The trimness and grace of these early reliefs had a charm for the artists and patrons of later times, especially the times of the first emperors, such as has been exercised in our day by the paintings of the pre-Raphaelite masters, and between the imitations then produced and the original models it is frequently difficult to draw a clear distinction. A critical list of these imitations—whether sculptured in relief or in the round—is given by Friederichs, *Bausteine*, i. pp. 71–95, and, with illustrations, by Overbeck, *Gesch. d. Griech. Plastik*, 2d ed., i. pl. 14. As examples of early sculpture in its inferior walk may be mentioned (10), a series of bronze statuettes which have served as stands of mirrors or otherwise as decorations of furniture. Those which have been or are still stands of mirrors are generally female figures, and it is to be observed that the oldest of them, as distinguished from the later examples, wear a heavy under-garment or chiton, apparently of worsted material, and over this again an ample and by no means light peplos.

Gem-engraving. If we are to credit the Greeks with having been introduced by the Assyrians to one branch of art more than another, we should say it was the art of gem-engraving. Not that we possess Greek gems which compare in style and antiquity with those of Assyria, but, if for no other reason, because we find a technical process of so great difficulty existing at all in Greece at an early period. Perhaps the earliest examples of the art in Greece possessed of artistic merit are two scarabs from Ægina, one with the figure of a bowman in pure Æginetan style, and the other bearing the inscription Κρεοντίδα εἰμί (*Bullettino d. Inst. Arch.* 1840, p. 140); three from Asia Minor, two of them being inscribed, the one Σήμονος, the other Ἀριστοτείχης (Brunn, *Gesch. d. Griech. Künstler*, ii. pp. 633 and 604). The only glyptic artist mentioned in this early period is Mnesarchus of Samus, the father of Pythagoras. In contrast with the paucity of early gems from Greek soil is the immense number of scarabs yielded by the tombs of Etruria, which at least reflect the style of this period. The material consists principally of rock-crystal, carnelian, and banded agate, and the subjects, it is worthy of remark, are mostly taken from the heroic legends of Greece, figures of deities being exceedingly scarce, as indeed is also the case on the Etruscan bronze mirrors, which, however, are obviously of a later date.

Painting, or rather colouring, as it would be more properly described in its earliest phase, in which it was entirely subservient to architecture and ceramography, is said to have been first elevated to an art by Cleanthes of Corinth, who introduced the drawing of figures in outline; by Telephanes of Sicyon, who improved on this by indicating the principal details of anatomy; and finally by Ecphantes of Corinth or Craton of Sicyon, by the introduction of colours (Pliny, *N. H.*, xxxv. 3, 15). Again we have Eumarus of Athens, who is said to have first distinguished in his paintings men from women, probably by the means adopted in the early vases, that is, by painting the flesh white in the case of women. The historical truth of these statements may be doubted; not so, however, those that refer to Cimon of Cleonæ, who made an unquestionable advance in the treatment of draperies, and in exchanging the conventional manner of rendering the human form for an approach to truthfulness to nature (Ælian, *Var. Hist.*, viii. 8; Pliny, *N. H.*, xxxv. 8, 6). Cimon appears to have been the founder of the early Peloponnesian school of painting. As the task imposed on painters at that time was mostly the decoration of the cella walls of temples, we must suppose that they executed their paintings on the prepared stucco of the wall either when it was fresh (*al fresco*), or when it was dry, by means of some binding material, *a tempera*. Like their followers down to the time of Apelles, they used only the simple colours, white, yellow, red, and bluish black, in the mixing of which to obtain other shades they seem to have advanced very little, greater attention being directed to the drawing than to the colouring. From the school of Asia Minor, which, from the proximity of the Lydians, Phrygians, and Phœnicians, with their long practice in working in colours, may have arisen earlier than that of the Peloponnesus, the first name we hear of is that of Bularchus, who, according to Pliny (*N. H.*, vii. 38, 126; xxxv. 8, 55), produced a large painting of the taking of Magnesia, which he sold to Candaules, king of Lydia, for its weight in gold. From the coast of Asia Minor our records of painting pass to Samus, an island which was conspicuous in early times for the grand scale of its undertakings. There Mandrocles, who made the bridge of boats across the Bosphorus by which Darius crossed with his army 515 B.C., executed a large historical painting of this passage of the Persians across the bridge, with Darius seated, enthroned, on the shore. This picture, according to Herodotus (iv. 88), was placed in the Heræum of Samus. To the Samian school belonged Calliphon and Agatharchus. It is also not unlikely that it had exercised some influence on Aglaophon of Thasus, the father and instructor of Polygnotus. From Corinth the art of painting, coupled with that of modelling in clay, passed to Etruria, lower Italy, and Sicily. At present the only examples of early Greek painting which we can adduce are furnished by the vases, a branch of the art which the ancients themselves regarded, it appears, with sufficient disrespect. For us, the vases, which have been preserved in great numbers, have this special value, that they present in an unbroken line, if in a comparatively degraded form, the various stages of Greek painting from its first beginnings under Oriental influence to its decline. The class which belongs to the period now before us is distinguishable from the others by the fact that the figures upon them are first scratched in outline on the red ground of the vase, and then filled in with black, the whole being covered with a varnish which seems to have lost nothing of its brilliancy. The other colours employed are white for the flesh parts of women and the hair of old men, white and a dark purple for the details of draperies and other accessories. The eyes are always placed full in profile, and the drawing of the figures is exceedingly stiff and angular. By far the greater part of this class of vases have been found in the tombs of Etruria, and for this reason they were called Etruscan, a designation which they retained till the frequency of Greek inscriptions, recording the artists' names upon them, contrasted with the total absence of Etruscan inscriptions, led to their being correctly traced to Greek workshops. As to their date, it has recently been argued by a high authority (Brunn, *Probleme in der Geschichte der Vasenmalerei*) that the greater part of these vases—in fact, all that have been found in Etruria, with at most two or three exceptions—are the production of Greek vase painters at a period not earlier than the end of the 3d century B.C., when a taste for the archaic manner must have revived. This theory has encountered much opposition. Applying it to the large collection of vases of this class from Etruria in the British Museum, one vase alone remains as a genuine example of the work of an early period. Whether we regard these vases as spontaneous productions or as imitations, they will serve to convey at best a dim idea of early Greek painting as a fine art. Of the next class of vases—those with red figures on black ground—some appear, from the severity of the drawing, to belong to the end of this period. The whole question of ancient vase-painting has been very fully and ably discussed by Otto Jahn in his Introduction to the *Vasen-Sammlung zu München*.

Painted vases.

Architecture.

In temple architecture the principles of both the Doric and Ionic orders were already fully established, the latter in Asia Minor and the former in Greece proper; and it is characteristic of the national importance attached to this branch of art, that not only was the best available talent of the time procured, irrespective of local connection, but also that architects appear to have found a public for the writings in which many of them narrated their proceedings, and described the appliances used by them in building, as did Chersiphron and his son Metagenes in regard to the temple of Diana at Ephesus; or laid down the principles they had followed, as did Theodorus with regard to the temple of Hera at Samus. Among the remains of Doric architecture assignable to this period, the first to be mentioned are the two temples at Pæstum (Major, *Les Ruines de Pæstum ou de Posidonie,* 1768; *cf.* Schnaase, *Bildende Künste*, ii. fig. 36), of which the larger derives a special interest from the two rows of columns, one above the other, with which it is furnished in the interior, for the purpose of supporting, as it appears, a hypæthral roof. Differing in many details from the Pæstum temple is that of Selinus, the sculptured metopes of which have already been described, and assigned to the commencement of this period. The columns are here slimmer, being 4½ times the lowest diameter in height; but the architrave has gained in height and heaviness. A transition from the heaviness of the old Doric temples—of Pæstum and Selinus, for example—to the graceful proportions of the Doric order in Attica is presented by the temple of Athene in Ægina, the columns of which, however, are still too short, being a little over 5 times the lowest diameter in height, and the architrave and frieze too high for the Attic-Doric style. Of the Ionic order during this period the principal example was the temple of Diana at Ephesus, the construction of which, begun by Theodorus of Samus, was carried on by Chersiphron of Crete and his son Metagenes, and completed by Demetrius and Pæonius about the time of Crœsus, 565–551 B.C., 120 years having, it is said, from first to last been consumed on the work (Strabo, xiv. 640; Vitruvius, vii. praef.; Pliny, *N. H.*, xxxvi. 14, 95). This temple having been burned by Herostratus, was restored under the direction of Alexander's architect Dinocrates. The oldest instance of the Ionic order in Greece proper, so far as we know, was found in the treasury erected at Olympia by Myron, the tyrant of Sicyon, after his chariot victory, 658 B.C. This building consisted of two chambers, the walls overlaid in the ancient manner with bronze plates, and the one executed in the Ionic, while the other was of the Doric order. The architects of this early time were not, however, restricted to the erection of temples, but had other problems to solve, as, for example, in the Scias of Sparta, a round building with tent-shaped roof, used originally for musical performances and afterwards for public assemblies. Theodorus of Samus was the architect of the Scias. Probably the Odeum erected at Athens by Solon or Pisistratus had the same round form, and was intended for meetings of the same kind. Then followed the construction of theatres, that in Athens, which was of stone, having been commenced shortly after 500 B.C.

Third Period.

The splendid victories of Salamis, Platææ, and Mycale, gave an immediate and powerful impulse towards public undertakings, and especially, so far as we are at present concerned, towards the erection of temples and monuments worthy of the just pride of the nation. A sense of freedom and relief from long and troublous fears must have been the ruling feeling of the time; and of the efforts, both intellectual and artistic, which such new-born feelings engender, history has its examples. Of all the Greeks, the Athenians had in that crisis earned the best title to patriotic emotions, and in Athens, above all Greece besides, the aspirations were highest. Nor were means wanting to second the boldest designs. The Peloponnesians had loitered in the great conflict with the Persians, and in sharing the new impulse they loitered also. The Persian invasion had not, however, been hurled back by a stroke of fortune, but, on the contrary, by the united action which discipline and severe habits of life gave to the Greek forces; and in the same way the men who thereafter achieved the first triumphs in art, who diffused freedom throughout its realm, were men who had been trained in severe schools, where close study, no less than respect for popular feeling, restrained the exercise of the imagination. Accordingly, before we can appreciate the artistic freedom established by Phidias, we must see how far his early training prepared him to fight the battle. This can only be done by examining the works of other sculptors, either pupils of the same master, as were Myron and Polycletus, or probably contemporary, though more hardened in the traditions of their school, as was Calamis the Athenian, with whom we begin, remarking that the only known approximate date in his lifetime is from 468 to 464 B.C. The works of Calamis extended over a tolerably wide field of subject, and were executed partly in marble and partly in bronze; but with the exception of two copies of his statue of Hermes Criophorus at Tanagra, on the coins of that town, and in a marble figure in Wilton House, none of our remains of ancient sculpture have as yet been identified with his style. Cicero (*Brut.*, 18, 70) and Quintilian (xii. 10, 7) speak of him as less rigid and hard in his rendering of the human form than Callon and Canachus; but the real advance with which his name is associated was in the rendering of expression in the female face, and in the treatment of draperies. A figure of Alcmene by him was highly praised (Pliny, *N. H.*, xxxiv. 19, 71), while his statue of Sosandra, on the Acropolis of Athens, is spoken of in the highest terms by Lucian (*Imag.*, 4, 6; *Dial. Meretr.*, 3, 2) for its chaste and tender expression, for its taste in dress, and for the noble bearing of the whole figure. His horses were always incomparable. To have attained the power of expressing modesty and mobile character in a figure was to have laid the foundation for idealism in its true sense; and Calamis was therefore on the same path with Phidias. Calamis

We come now to Myron, a native of Eleutheræ in Attica, and a pupil of Ageladas of Argus. With rare exceptions, he worked in bronze, and that of the Æginetan kind, while Polycletus employed the bronze of Delus. His works, which were numerous, and scattered from Asia Minor to Sicily, may be divided into the four classes of deities, heroes, athletes, and animals, with a considerable variety ranging within each of the classes. He avoided female figures almost throughout; and though he was the author of statues of Dionysus and Apollo, it should be remembered that these deities had not become soft of form till Praxiteles made them so. He preferred the well-knit figures of athletes, or of Perseus or Hercules. His animals were marvels to the ancients; and the human figures in which he succeeded best were those in which purely physical qualities were pronounced. "Corporum tenus curiosus, animi sensus non expressit," says Pliny of him. But, according to the same authority, he was careless in rendering the hair, from which it is to be inferred that his study of the human form did not lead him, as it did Pythagoras, to an anxious reproduction of all its details. Then we have the further statement of Pliny—"Primus hic multiplicasse veritatem videtur, numerosior in arte quam Polycletus, et in symmetria diligentior." As we understand "multiplicasse veritatem," it would mean that he exaggerated the truth of nature to give effect to the momentary attitude of his Myron.

figures. "Symmetria" we take to refer to the manner in which every member and part of the body was made to work together for the expression of one moment of action. Such a style at least presents a very obvious contrast to that of Polycletus, and would answer our expectations when we read that Myron's statue of Ladas seemed about to leap from its base to seize the victor's wreath, the last breath leaving his lips. (For a different interpretation see Brunn, *Gesch. d. Griech. Künstler*, sub Pythagoras). Among his figures of animals, that of a bronze cow which stood on the Acropolis of Athens, and was afterwards removed to the temple of Peace in Rome, was celebrated by numerous epigrams. Of his other works, some have been preserved in copies down to our own time. A copy of the figure of Marsyas (from his group of Athene and Marsyas) has been recognised in a marble statue in the Lateran Museum (*Mon. d. Inst.*, vi. pl. 23; *Annali*, xxx. p. 374). Of his bronze statue of a Discobolus, famous in antiquity (Quintilian, ii. 13, 10; Lucian, *Philops.*, 18) for the boldness of its movement and the carefulness of its execution, we have several copies, of which the best is the marble statue in the palace Massimi at Rome (Müller, *Denkmäler*, i. pl. 32, No. 139, *b*). Another marble copy in the British Museum has not only had its head (if original) placed on the shoulders the wrong way, but has been made smooth on the surface by a vigorous rubbing down, which has destroyed the original lines. A third copy of bronze, about a foot high, is in Munich. (For a list of his other works, known only by name, see Overbeck, *Ant. Schriftquellen*—Myron.) From the few copies of his statues which we possess, and the few ancient remarks as to his style, it seems impossible to frame a conception of his work which would justify the extraordinary reputation he enjoyed. We can picture the action of his figures, but we cannot estimate the equivalents for actual life and organism which he must have employed to have almost completely satisfied eyes accustomed to the work of Phidias. This, however, we gather from the remarks on his statue of Ladas and the Discobolus, that he seized for his representation the moment when the whole breath was held back for a final effort of strength—that moment, in fact, when the human figure is most truly statuesque. For an instant the body is then lifeless, so to speak, like the statue itself: the spectator suspends breathing, in sympathy.

We have reached the time of Phidias, and have now done with imperfections in sculpture, so far at least as they originated in want of knowledge either of the human form or of technical means. Phidias, the son of Charmides, was an Athenian, and must have been born about 500 B.C., or a little before, if we can trust the statement (Plutarch, *Pericl.*, 31) that in the portraits of himself and Pericles, which he placed on the shield of Athene Parthenos, he appeared a bald-headed old man, while Pericles appeared handsome and full of vigour (K. O. Müller, *De Phidiæ Vita et Operibus Commentationes Tres*, Gotting. 1827; Brunn, *Gesch. d. Griech. Künstler*, i. p. 157). A fragment of a marble shield in the British Museum, found on the Acropolis of Athens, and representing a combat of Greeks and Amazons, in which a bald-headed old man appears, has been recognised as a rough copy of the shield in question. Phidias began his career as a painter; then turning to sculpture, studied first under his townsman Hegias, and afterwards under the Argive master Ageladas. It may have been due to his training in this school that his first two important works were executed in bronze. The first was a large group, commissioned by the Athenians to be paid for out of their booty from the Persian war, and to be dedicated at Delphi. The second was a colossal statue of Athene, the Promachos, also commissioned by the Athenians out of the Persian booty, and when finished erected on the Acropolis, between the Propylæa and Erechtheum, the top of the spear which she held, and the crest of her helmet being visible at sea from Cape Sunium (Pausanias, i. 28, 2). On certain coins on which the Acropolis is figured occurs a statue which seems to correspond with the description, except that the goddess there stands placidly, an attitude that does not suit the idea of a Promachos. This idea is finely embodied in a small bronze statuette (fig. 5), found on the Acropolis and now in the British Museum, representing the goddess striding forward. Otherwise it has little of Phidias in it. Possibly the Promachos statue was wrongly ascribed to Phidias in ancient times. Again profiting by the Persian spoils, he was employed by the Platæans to execute a figure of Athene Areia for their new temple (Pausanias, ix. 4, 1). The figure was of wood, covered with gold; the face, hands, and feet, of Pentelic marble; the whole being of colossal proportions. He had previously made a figure of Athene in gold and ivory for a temple at Pallene in Achæa, and this must be regarded as the first of his works executed in the material in which he afterwards achieved his greatest triumph (Pausanias, vii. 27, 2).

FIG. 5.—Bronze statuette. Brit. Mus. From Athens.

We must suppose that his faculties were now at their best, that he was fully aware of the peculiarities of treatment required by the different materials in which sculptors then worked, and had found the best scope for his own talent in chryselephantine sculpture. The two works with which his fame was chiefly associated were in gold and ivory,—the colossal statues of Athene for the Parthenon at Athens, and of Zeus for the temple at Olympia. After the completion of the former statue, Phidias accepted the invitation of the people of Elis to exert his highest power in fashioning for their temple of Zeus at Olympia a statue worthy of the majesty and grandeur of the supreme god of Greece. His workshop was near the Altis or sacred grove, where through successive centuries down to the 2d A.D. it was preserved and pointed out with feelings of reverence. The finished work was over 40 feet high, and represented the god seated on his throne, his right hand holding forward a figure of Victory, and his left resting on a sceptre on which the eagle was perched. On his head was a wreath of olive. The drapery was of gold, richly worked with flowers and figures in enamel, in the execution of which he was assisted by his brother or cousin Panænus. On the footstool was inscribed the verse—

Φειδίας Χαρμίδου υἱὸς Ἀθηναῖος μ' ἐποίησε

(Pausanias, v. 10, 2). The throne was mostly of ebony and ivory, inlaid with precious stones, and richly sculptured with reliefs, and in parts painted. Of this, the greatest work of Phidias, nothing but the description now remains (Pausanias, v. 15). The figure of Zeus seated on a throne, which occurs on coins of Elis struck in Roman times, may have been intended as a reminiscence of it. On the other hand, there is in the British Museum a silver coin of Elis, struck in the best period of Greek art, on which is a head of the god so singularly powerful in type that we are tempted to believe it to be a copy from the head of the statue of Phidias, appealing to the analogy of the coins of Argus with what is accepted as a copy of the head of the figure of Hera by Polycletus. Among the existing examples of Greek sculpture there is only one which claims to be a direct work of Phidias, and that is one of the two colossal marble statues on the Monte Cavallo at Rome; inscribed respectively "opus Phidiæ" and "opus Praxitelis" (Clarac, *Musée de Sculpture*, pl. 812 A, No. 2043). Grand as both are, the marking of the pupils of the eyes and the treatment of the armour prove them to have been executed in Roman times, probably as copies of celebrated statues. The originals must clearly have been the work of one master, and the inscriptions being thus wrong in ascribing them to two, must be held as worthless. On the other hand, we possess in the sculptures of the Parthenon a large series of works in marble at least designed or modelled by Phidias, and executed under his immediate care, if not in many cases finished by his own hands. These sculptures consist of figures in the round from the pediments, the metopes in high relief, and the frieze in low flat relief. The statues of the pediments have suffered most, and that mainly from two causes—the antipathies or necessities of the early Christians, who converted the temple into a church; and the fatal explosion produced by the falling of a shell among the powder stored in it during the Venetian bombardment under Morosini, 1687. The extent of the mischief on this occasion is known from the drawings previously made of the temple as it stood, 1674, by Carrey, an artist in the employment of the French ambassador at the Porte. In 1805, Lord Elgin, then British ambassador at the Porte, removed all the sculptures that could be removed with safety to the building, shipped them to London, where, after a long dispute as to their merits, they at last, in 1815, found a permanent resting-place in the British Museum. (For a narrative of these proceedings, but especially for an exhaustive work on the Parthenon, see Michaelis, *Der Parthenon*, Leipsic, 1871; the sculptures are best engraved in *Museum Marbles*, vol. vi.; the fragments in Athens, in Laborde, *Le Parthénon*, pls. 26–28). The subject of the eastern pediment was the birth of Athene; of the western, her contest with Poseidon for supremacy over Attica; but beyond the simple statement of Pausanias to this effect, we have no ancient record to enable us to identify the personages before whom these events took place. Hence the many different names which have been proposed from time to time for the surviving figures, especially for those of the eastern pediment, from which all the principal statues had disappeared before Carrey's time. Assuming, however, with the most recent authority (E. Petersen, *Die Kunst des Pheidias*, 1874), that the birth of Athene took place in Olympus, and that the deities assembled at the birth of Aphrodite, as represented by Phidias on the base of the statue at Olympia, were the recognised Olympians of his time, we obtain, beginning from Helios on the left, Dionysus, Demeter, and Core, Iris [Apollo, Artemis, Hephæstus, Athene, Zeus, Hera, Poseidon], Nike [Ares, Hermes], Hestia, Peitho, Aphrodite, and Selene, those in brackets being missing. The western pediment has suffered a much harder fate, though the difficulty of recalling the lines of the original composition is less, owing to the preservation of drawings made by Carrey before the bombardment which destroyed it. The metopes were ninety-two in number; those of the east and west only remain on the building, but have suffered severely from malicious destruction. Those of the north side, which survived the explosion, remain in Athens in bad condition; those of the south were removed by Lord Elgin, with the exception of one now in the Louvre and some fragments in Copenhagen. The subject—a favourite one in the decoration of Greek architecture—was a combat between Centaurs and Lapithæ. Traces of red colour were found on the ground of the relief and of green on the draperies. The armour had been attached in metal, as is proved by the existing holes for that purpose. Differences in style as well as in execution prove the variety of hands employed in the work, though everywhere is apparent the oneness of design which bespeaks the overseeing master. The variety of hands is equally manifest in the frieze, but here it takes the form of insufficiency of execution, which no doubt arose from the difficulty of supervising work which had to be done up on the building. The subject of the frieze is a long festal procession, in which, though every variety of movement of horse and foot, of young and old, of men and women, perhaps of gods and goddesses, is introduced, the calm dignity of national pride and the knowledge of national worth reign supreme. Its entire length is 524 feet, its height from the ground 40 feet, its relief very low and flat. About two-thirds of it is preserved, nearly the half being in the British Museum. As to the procession itself, there are two opinions: either it is the procession with which it was usual to accompany annually the newly-made robe for Athene Polias, or it is the procession in which the victors at the Panathenaic games advanced to the Parthenon to receive their prizes and to attend a sacrifice in honour of Victory.

Sculptures of the Parthenon.

The mantle of Phidias fell on his pupil Alcamenes (Pausanias, v. 10, 8), an Athenian, or, as others said, a Lemnian, the lofty conception in his figures of deities being highly praised (Quintilian, xii. 10, 8), while in point of gracefulness in womanly forms he appears to have excelled his master. His most celebrated work was a statue of Aphrodite for her temple, ἐν κήποις, of which, however, the merit of the last touch was ascribed to Phidias (Pliny, xxxvi. 5, 16). Her cheeks, hands, and fingers were specially admired; but as to the attitude and general effect we have no information, and are not justified in accepting the Aphrodite of Melus in the Louvre as a copy of it, much less the original work. How far he may have been possessed of the power of creating new ideal types is not expressly recorded, except in the instance of his statue of a triple Hecate, probably such as we know her in later works. On the other hand, there was doubtless scope for extending the new influence of Phidias in such types as those of Æsculapius, Hephæstus, and Ares, and it has been conjectured that in his statues of these deities he succeeded in infusing the spirit of his master.

Alcamenes.

Scarcely less famous was another pupil of Phidias, Agoracritus of Parus, who so far identified himself with the master's style that two marble statues of deities by him were sometimes ascribed to Phidias. The one was a figure of Nemesis in Rhamnus; the other, a statue of Rhea in the Metroon at Athens (Pausanias, i. 3, 5). From his hand were also the bronze statues of Athene Itonia and of Zeus, in the temple of that goddess between Alalcomenæ and Coronea (Pausanias, ix. 34, 1). Next we have Colotes and Thrasymedes of Parus, both of whom occasionally aspired to retain the chryselephantine technique of the master, and finally, Theocosmus of Megara.

Successors of Phidias.

How far the immediate successors of Phidias remained, whatever their peculiarities or eccentricities, still faithful to the general sentiment and manner of the master, merely varying but always preserving essentially the theme struck by him, cannot be ascertained, unless we take the sculptures of the temple of Athene Nike at Athens, or of the Erechtheum, as typical examples of their work. And indeed they are well calculated to produce the impression of having been executed during the lull which must have followed his great impulse. (For the relief on the frieze and balustrade of the temple of Nike, compare Friederichs, *Bausteine*, i. pp. 187–193; Ross, *Der Niketempel;* Kekulé, *Die Balustrade des Niketempels*.) The treatment of the draperies has entirely lost the stiffness and formality of an early period, and become flowing, as in the style of the best times, but with the addition of a studied grace which seems due to a desire to elaborate more and more the simplicity of the draped figures of the Parthenon. The most probable date as yet suggested for this temple is 407 B.C. As to the Erechtheum, we have 406 B.C., on the authority of an inscription, as a year in which a report was made concerning the amount of work that remained to be done upon it. Of its sculptures the chief remains are the statues of the Caryatides, and certain fragments of the frieze, which had this peculiarity, that the reliefs were executed in Pentelic marble, and then attached to a ground of black Eleusinian stone. Of the original six Caryatides which supported the portico, five were in position in the time of Stuart and Revett in the first half of last century; the sixth, having been broken to pieces, was recovered in 1837. One of the five was removed by Lord Elgin, and is now in the British Museum. In the arrangement of the draperies vertical lines prevail; but only enough to show the architectural purpose of the figures, not to destroy their character as robes, or to affect their gracefulness. It is usual to compare with the sculptures of these two temples another series of reliefs which, though not found in Attica, are stated to have been the work of Ictinus, the architect of the Parthenon. We refer to the frieze from the temple of Apollo at Phigalia which was discovered in 1812, and is now in the British Museum. The subjects represented are combats between Greeks and Amazons and between Centaurs and Lapithæ. In the composition the old ethos has given way to pathos; but the figures are still large in conception, and obviously studied with a view to truth as well as effect, though in the execution probably by provincial hands, many minor details have been overlooked. The energy of action throughout is not equalled in any other ancient sculpture now in existence, while the sense of pain in the wounded, or of fright in the helpless women who run with their infants in their arms, makes the spectator shudder. From the fact that such vigour of action and intensity of pathetic expression have not been found in the metopes of the Parthenon or the frieze of the Theseum which are devoted to the same subject, but recur in a less degree in the frieze of the Mausoleum, there is an inclination to place the Phigalian reliefs by Ictinus in as late a period as possible after the erection of the Parthenon. (Engraved, *Museum Marbles*, vol. v.; Stackelberg, *Der Apollotempel zu Bassæ*, 1828; see Friederichs, *Bausteine*, i. pp. 178–181.)

The difference of temperament between the Athenians and Peloponnesians was strongly marked in the schools of sculpture peculiar to each. Political rivalry had its exact counterpart in artistic rivalry, in which Phidias

Polycletus. represented Athens, and Polycletus the Peloponnesus. The works of the latter appear to have been always chastened with an hereditary severity, to have been attractive by the purity of their style and the finish of execution, but not commanding in aspect. "Non explevisse deorum auctoritatem videtur," the judgment of Quintilian (xii. 10, 7) is endorsed by the statement, that his great work, the chryselephantine statue of Hera at Argus, yielded to the statue of Zeus at Olympia by Phidias in grandeur and imposing aspect, but outrivalled it in finish (Strabo, viii. p. 372). Copies of the head of this statue have been identified on coins of Argus, and in three marble heads of colossal size. The first, in Naples, is severe in style, and may have been executed about the time of Polycletus; the second, in the British Museum, has more freedom, but is still chastened by a severe expression; the third, in the Villa Ludovisi, bears the marks of having been executed at a still later period. It was not, however, in producing statues of deities that Polycletus delighted most; and if surpassed by Phidias in that instance, he was quite without a rival in his own province, the rendering of the form of ideal athletes. Of this class were his Diadumenus, his Doryphorus, and a third figure (unless the Doryphorus was meant by Pliny) known as the Canon. Of the first, several presumed copies in marble exist, two of them in the British Museum (fig. 7), but in no case furnishing an adequate illustration of his style. The same may be said of the copies of the Doryphorus. More in the nature of *genre* work was his bronze group of boys playing with knuckle-bones (ἀστραγαλίζοντες), which afterwards stood in the palace of Titus in Rome, and was by some regarded as the most perfect work of the master. This motive occurs in several existing sculptures, in no case characterised by a trace of the hand of Polycletus. Among them are, in the British Museum, a small group in terra-cotta of two women playing at this game, and a marble figure of a boy, part of a group, biting his companion's hand. Coupled with his statue of Hera, that of an Amazon, executed by him for Ephesus, in competition with the foremost of his contemporaries, and adjudged the prize, will prove that the range of his talent was by no means confined to figures of athletes; and this is made further apparent by his bronze statues of maidens carrying sacred vessels on their heads, afterwards in the possession of Heius the Mamertine, from whom they were taken by Verres (Cicero, *In Verr.*, iv. 3, 5), as also by his statue of the Samian, Artemon, nicknamed ὁ περιφόρητος.

FIG. 6.—Bronze statuette. Brit. Museum. From the collection of the late Mr Woodhouse, Corfu.

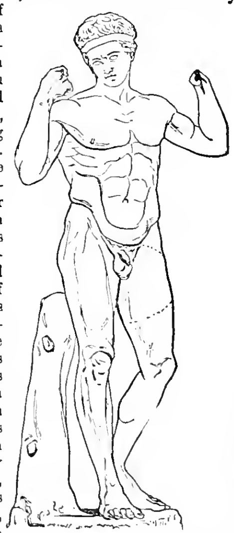

FIG. 7.—Diadumenus. Marble statue. Brit. Mus. Found at Vaison (*Vasio*), Dept. Vaucluse, France.

None of the pupils of Polycletus arrived at distinction. On the other hand, his **Pupils of Polycletus.** style appears to have been closely followed by his younger contemporary, Naucydes of Argus, who executed a chryselephantine statue of Hebe, to accompany that, of the same material, by the master already described (Pausanias, ii. 17, 5; Kekulé, *Hebe*). A pupil of Naucydes was Polycletus the younger, of Argus, who is known as the author of several statues of victors at Olympia, and of a statue of Zeus Philius (Pausanias, viii. 31, 4), in which the expression resembled that of Dionysus.

In addition to the existing sculptures already mentioned in connection with one or other of the ancient masters, there are others which, though their authorship has not been ascertained, undoubtedly belong to the period now before us. From these we select—(1.) A marble relief in Athens, found at Eleusis in 1859, and representing Demeter, Cora, and boy, for whom the name either of Triptolemus or Jacchus would be applicable (*Monumenti*, vi. pl. 45.) With the exception of a marked severity both in the composition and in the details, which may be due either to archaism or to a studied solemnity, this relief compares admirably with the frieze of the Parthenon. (2.) From Eleusis also comes the upper part of a female figure supporting a basket on her head (Calathephorus), now in Cambridge, in a large fine style (Wieseler, *Denkmäler*, ii. pl. 8, No. 92). (3.) Marble relief of Orpheus and Eurydice, in the Villa Albani, with its two replicas in Naples and Paris. (4.) Fragments of the metopes from the temple of Zeus at Olympia, found in 1829, and now in Paris. Doubtless these reliefs were executed at the time when Phidias was at Olympia engaged on the statue for this temple, and when his pupil Alcamenes was at work on the figures for the western pediment of it. In style, however, they differ considerably from that of the Attic sculptors; nor are there any means of identifying them with the style of Pæonius of Mende, who executed the statues for the eastern pediment (*Expédit. Scientifique de la Morée*, i. pls. 74, 78.) (5.) The metopes and inner frieze of the temple of Theseus at Athens are still in their original place, the style being compared with that of the metopes of the Parthenon, though the temple itself is usually believed to have been built by Cimon (Stuart's *Antiquities of Athens*, 2d ed., ii. pl. 19)

Examples of what may be called a lower branch of sculpture (gem-engraving) are exceedingly rare in this period. So far as Athens is concerned, this will appear less remarkable if we suppose that gem-engraving and die-sinking were one profession, and remember that at least the latter must have been, with few exceptions, unpractised there in the best period, the coins being allowed, probably for commercial reasons, to retain the old stamp with which people were familiar. Possibly also the high ideal of the times was above the grasp of such artists, though it was seized pretty generally by the sculptors of stelæ, who could hardly have been men of note. In the British Museum is a carnelian (fig 8) representing a youthful figure, seated, and playing on a harp-shaped instrument, which, with a little severity, admirably reflects the style of the Parthenon frieze. Of the coins of Sicily, the large piece known as the Demaretion, and struck in the year 479 B.C., furnishes an example of the rendering of horses, which compares finely, if more advanced, with the archaic frieze from Xanthus. Similarly worthy of study are the coins of Gelon, which are probably as early as 470 B.C., and certainly are anterior to 410 B.C.

FIG. 8.—Carnelian intaglio. Brit. Mus. From the collection of the late Mr Woodhouse, Corfu.

Painting. In the records of painting during the previous period it was noticeable that painters even then, in what appeared to be one of the earliest stages of the art, were accustomed to execute large compositions, such as battle scenes. The essentially decorative character of the art required that it should be so, just as in early sculpture, in which also the decorative element prevailed, our principal records are those of large compositions, such as the chest of Cypselus or the shield of Achilles. While the epos flourished, and the country was full of heroic legends, there can be little doubt but that the principal pleasure derived from works of art lay in the variety of the subject and the manner in which it was presented, that is, in the composition, and not in the truthful rendering of individual forms. To heighten the interest of the spectator, it was usual to write the name beside each of the persons that appeared in a picture, as we see it done on the early vases. The same was the case with the sculptured reliefs on the chest of Cypselus, which on this account presents a remarkable contrast to the shield of Achilles, on which, as in Assyrian sculptures, there is no prominence of individuals, and therefore no accurate study of the human form. It is not to be supposed that in the early stage of Greek painting individual forms were studied with any other view than that of rendering the characters more intelligible; but with this a beginning was made to lift the art into a higher sphere. At this stage appeared Polygnotus, a native of Thasus, and a son of the painter Aglaophon, of whose probable connection with the early Samian school mention has already been made. Attracted to Athens by the opportunity presented by the new buildings which were then being erected, Polygnotus, either owing to some family tie or through the recommendation of his own ability, found favour with Cimon, to whose zeal and taste the new impulse for the improvement of the city was due. In company with, or perhaps rather with the assistance of, the Athenian painters Micon and Panænus (the brother or cousin of Phidias), he was employed to execute wall paintings for the Stoa Pœcile, the Theseum, and the Anaceum, or temple of the Dioscuri, at the northern foot of the Acropolis. For his services, and especially for the disinterestedness of his character, Polygnotus received what was then regarded as the highest distinction—the freedom of the city of Athens. His friendship with Cimon was intimate, and led, it was said (Plutarch, *Cimon*, 4), to an affectionate acquaintance with Cimon's half-sister, the beautiful Elpinice. From Athens he was called to Delphi to execute a series of paintings for the two long walls of the Lesche, a building erected there by the people of Cnidus. The paintings, however, appear to have been commissioned by the Amphictyonic council, if it is right to be guided to that conclusion by the statement that the painter was rewarded with the rights of hospitality throughout the states included in the Amphictyonic league. On the wall to the right after entering the Lesche were painted scenes illustrative of the old epos of the taking of Troy (Ἰλίου πέρσις). On the left was the visit of Ulysses to the lower world, as described in Book xi. of the *Odyssey*. The names of most of the persons were written by the side of the figures. The various groups and incidents depicted we know from the description of Pausanias (x. 25–31); and with the help of existing works of art in which the same subject recurs, we can form an idea of the composition (O. Jahn, *Die Gemälde des Polygnotus in der Lesche zu Delphi*, 1841; Welcker on the same subject in the *Abhandlungen* of the Berlin Academy, 1847; Watkiss Lloyd, in the *Museum of Classical Antiquities*, i. p. 44). Heydemann (*Iliupersis*, Berlin, 1866) republishes, for the illustration of his other figures, the famous Vivenzio vase in Naples (*Mus. Borb.*, xiv. pls. 41, 43), which, pregnant with pathos as no other vase in existence, cannot well be identified with the style of Polygnotus, unless perhaps as regards the composition. He was employed at Thespiæ on a stoa or temple, but from some defect his work had perished so far within a century after it was

Polygnotus.

finished that it had to be restored by Pausias of Sicyon. At Platææ he painted for one of the walls of the pronaos of a temple the scene in which Ulysses appeared with the dead suitors at his feet. The companion picture was by an otherwise unknown artist, Onasias, the subject of it being the Expedition of the Seven against Thebes (Pausanias, ix. 4, 2). Lastly, Pausanias (i. 22, 6) ascribes to Polygnotus a series of paintings in the so-called Pinakotheke on the Acropolis of Athens. If he is right, the painter must then have been full seventy years of age. The subjects were—(1.) Ulysses carrying off the bow of Philoctetes; (2.) Diomede carrying off the Palladium of Troy; (3.) Orestes and Pylades slaying Ægisthus and the sons of Nauplius, who had come to his aid; (4.) Polyxena about to be sacrificed to the manes of Achilles; (5.) Achilles in Scyrus; and (6.) Ulysses meeting Nausicaa and her maids. The other pictures had become unrecognisable through the effects of time. This second mention of the decay of his works reminds us of the fleeting nature of the material with which the fame of the great painter was bound up. It was well that high honours were paid him in his lifetime. The enduring marble in which Phidias worked has preserved his fame to our times, to mock the indignities which he suffered in life. As regards the style of Polygnotus, we have the distinction drawn by Aristotle (*Poet.*, 2, 6; *Polit.*, viii. 5) between it and that of Zeuxis—a distinction which he expressed by the words *ethos* and *pathos*. By ethos, as applied to the paintings of Polygnotus, we understand a dignified bearing in his figures, and a measured movement throughout his compositions, such as the Parthenon frieze presents, compared with the pathetic rendering of scenes in the frieze from the temple of Apollo at Phigalia, or in the frieze of the Mausoleum at Halicarnassus. It was also said (Pliny, *N. H.*, xxxv. 35, 58) that in place of the old severity and rigidity of the features he introduced a great variety of expression, and was the first to paint figures with the lips open; and further, he was accredited (Lucian, *Imag.*, 7) with great improvements in the rendering of drapery, so as to show the forms underneath. He painted in monochrome on a white ground; so that, in fact, the principal charm of his work must have been in the drawing. His brother Aristophon appears to have also inherited an elevated conception and a power of carrying out large compositions. Among the younger contemporaries of Polygnotus were Dionysius of Colophon, laboriously accurate, and Pauson, the butt of Aristophanes (*Thesmoph.*, v. 949, and elsewhere), remarkable for his talent of caricature and animal painting.

Painted vases. The works of these painters have entirely perished, nor in what remains of the work of their humble imitators, the vase painters, is there much that can be justly regarded as reflecting their style. Besides the Athenian lecythi, which give some sort of an idea of the effect of colours as employed by Polygnotus, there is a class of vases, with red figures on a black ground, which, by the treatment of the drapery as a transparent substance, recall the statement to the same effect made in respect of the great painter. In many cases, also, the figures are large in conception and measured in their movement.

Architecture. The history of architecture during this period is an unexampled record of great undertakings throughout Greece, but more especially in Athens, which, if it had suffered most from the Persian invasion, had also in the end acquired the most ample means of repairing its ruins and adding fresh lustre to its aspect. Themistocles having been banished, the administration and the carrying out of works begun by him—such, for example, as the long walls connecting the city with the harbour—fell to Cimon. The city walls on the south side of the Acropolis were rebuilt, and a tower erected to command the entrance, which, however, being afterwards rendered useless by the erection of the Propylæa, was removed to make way for the temple of Athene Nike. Among the new temples the first to be mentioned is the Theseum, which is not only well preserved still, but is also the oldest existing example of the Attic-Doric order (Stuart and Rivett, *Antiquities of Athens*, iii. pl. 7). The other temples, the erection of which may with great probability be traced to Cimon, are the Anaceum, or temple of the Dioscuri, at the foot of the Acropolis, on the north side; and a small temple, now quite destroyed, on the left bank of the Ilissus, which existed in Stuart's time, and, from his drawing (*Antiquities of Athens*, i. pl. 7), is seen to have been of the Ionic order, differing from the Attic-Ionic in wanting the dentils of the cornice, in having the base of its columns composed of a trochilus between two spirals, and in having its architrave quite plain. Cimon was succeeded by Pericles, under whose administration the resources of the city, not only in means, but in the talent of using the existing means, were applied with the greatest judgment and energy, foremost among his advisers being Phidias. According to Plutarch (*Pericl.*, 133), Phidias exercised a general supervision over all the public works then going on. Apparently at this time was erected the Odeum, a building intended for musical performances, circular in form, and, as appears from the records of it (Vitruv., v. 9; Pausanias, i. 20, 4), brilliantly decorated with numerous columns in the interior, and with a tent-shaped roof of wood. It was the Acropolis, however, that was reserved for the crowning effort of architecture in this period. Within the space of probably not more than five or six years there rose on the site of an old temple of Athene, which had been destroyed by the Persians, the Parthenon, a model for all time of the Doric order, pure and perfect in its architectural forms and proportions. The architect was Ictinus, who was assisted by Callicratidas (Stuart, *Antiquities of Athens*, ii. pl. 7; Penrose, *An Investigation of the Principles of Athenian Architecture*, 1851; Beulé, *L'Acropole d'Athènes;* Bötticher, *Bericht über die Untersuchungen auf der Akropolis von Athen*, 1862; Michaelis, *Der Parthenon*, 1871). The next undertaking was the so-called Propylæa, a building which, though practically serving as an entrance to the Acropolis, aspired to a highly decorative character (Stuart, *Antiquities of Athens*, ii. pl. 42). The architect was Mnesicles. Contemporary with the building of the Propylæa, it appears, was that of the small temple of Athene Nike, on the Acropolis, which, on the removal of a Turkish structure in 1835, was recovered in almost all its parts, except some slabs of the frieze, brought by Lord Elgin to England, and now in the British Museum (Beulé, *L'Acropole*, p. 124; Kekulé, *Die Balustrade des Niketempels*). Outside of Athens the example of the Periclean activity was felt at Eleusis, where a great temple for the Mysteries was commenced, from designs by Ictinus, and carried to completion by the three successive architects, Corœbus, Metagenes, and Xenocles. The small temple, *in antis*, of Artemis Propylæa at Eleusis probably belongs to this period, as does also the temple of Nemesis at Rhamnus, of which we have still important remains. There is yet to be mentioned the Erechtheum, or temple of Athene Polias, on the Acropolis of Athens, which, though the only date we possess of it falls after the death of Pericles, bears the strongest impress, both in its architectural and sculptured forms, of the great age. The date referred to is the twenty-third year of the Peloponnesian war, and occurs in an inscription found on the Acropolis in several pieces, in which is given the report drawn up by a commission appointed to inspect the progress of the works (Inwood, *The Erechtheum of Athens*, 1827; Rangabé, *Ant. Hell.*, Nos. 56–60; *Corpus*

Inscript. Græc. No. 160). In the British Museum, besides part of this inscription, are several specimens of the architectural decoration, and one of the Caryatides (or draped female figures who supported the portico), in which the simplicity of the drapery and the dignity of the pose are quite in the spirit of the Parthenon sculptures. The temple of Apollo Epicurius at Phigalia, in Arcadia, the work of Ictinus, the architect of the Parthenon, necessarily belongs also to this period (Cockerell, *Temples of Jupiter at Ægina and Apollo at Phigalia*). The great temples at Olympia and Delphi, though begun earlier, may also be reckoned among the works of this period, to which also belongs a large séries of Doric temples in the Greek towns of Sicily and Magna Græcia, particularly those of Syracuse, Agrigentum, Selinus, Egesta, and Metapontum. Of these the most remarkable are the southern temple in the lower town of Selinus, and the somewhat more recent temple of Zeus at Agrigentum.

Fourth Period.

Since the beginning of our last period, the political and social circumstances of Greece have suffered a marked change. More or less it was then accepted as a dogma that, provided the state was flourishing, the prosperity of individuals mattered little. All were for the state, and by their union in the state's emergency had achieved a glorious freedom, the sense of which filled the national mind, and prepared it to respond with a fostering sympathy to the efforts of artists, whom it also inspired. Yet, conscious as they must have been of their own services, the men of that generation turned rather in pride to the deeds of their ancestral heroes, and in humility to the assistance of the gods. They sought to frame their conduct on the traditions of the past. They were rigorous and strong in thought. Passion was a thing to deplore, not to study, analyse, and represent. The national history was still unchequered. Nor was the house of Hellas as yet to any degree openly divided against itself. There was no need of artists—whether poet, as Æschylus, or sculptor, as Phidias—to depict the struggles of passion or other conditions of the mind. Now this is all changed. The nation has lost its unity, and the Peloponnesian war has made havoc of its resources. Æschylus has given way to Sophocles and Euripides, Phidias to Scopas and Praxiteles. Poets and sculptors of the new generation have chosen as their theme the representation of pathos and of the conditions of the mind generally. That such was the character of what is called the second Attic school of sculpture is known principally from the records of artists. Of works directly from the hand of any of the masters of this school there is no example in existence, so far as we know at present. On the other hand, there are many copies of their works, from which, with the aid of records, some idea may be formed of their style.

The first of the artists of this school was Scopas, a native of Parus, and, as it would seem, the son and pupil of Aristandrus, a worker in bronze, in which material the son appears to have commenced his career as a sculptor. An example of his work in bronze was the statue of Aphrodite sitting on a goat, in Elis (Pausanius, vi. 25, 2). This subject occurs on a fragmentary cameo in the British Museum. Marble, however, was a material more congenial to his style. The first years of his activity were spent in the Peloponnesus, and particularly at Tegea in Arcadia, where the erection of a temple, in honour of Athene Alea, in the place of one that had been burned 395 B.C., was under his direction as regards both the architecture and the sculpture. About 380 B.C. he settled in Athens, where for nearly thirty years he maintained a reputation for an unparalleled power of rendering the human or divine figure, not imposing, but attractive by the charm of bearing, and the expression of that feeling which for the moment the person was most sensitive to. Sometimes this feeling was one of excited passion accompanied by great bodily agitation, as for example, in the case of his statue of a Mænad at Athens, in the attitude of rushing with head thrown back and streaming hair, and holding a slain kid in her hand. At other times the passion he sought to express was one of peaceful inspiration, as in the statue of Apollo Citharœdus, with long flowing robe and head thrown back as in a dreamy enjoyment of the strains from his lyre. When considerably advanced in life, possibly over sixty years of age, Scopas was invited by Artemisia, the queen of Caria, to assist or direct the sculptures for a monument which she was erecting at Halicarnassus in memory of her husband Mausolus. Accompanied by Bryaxis, Leochares, and Timotheus (or Praxiteles, as others said), he proceeded thither, but as to what part he had in the work we have no information. The site of the Mausoleum was discovered and excavated by Mr C. T. Newton in 1856–7, the result being the recovery of an important part of the sculptures, which, with the slabs of the frieze previously known, now constitutes the principal illustration of the art of that time (Newton, *Discoveries at Halicarnassus, Cnidus, and Branchidæ*, 1862). While occupied on the Mausoleum, or after its completion, Scopas executed several sculptures for other towns in Asia Minor, as at Cnidus, Ephesus, and Chryse in the Troad. In a temple of Neptune, erected in Rome by Cn. Domitius Ahenobarbus, was a large composition by Scopas, representing Poseidon, Thetis, and Achilles, attended by nereids riding on dolphins and hippocamps, and by tritons and other marvellous creatures of the sea. Not as a copy of this work, but as reflecting vividly the manner of this sculptor, has been accepted the large marble relief in Munich (O. Jahn, *Berichte der Sächs. Ges. d. Wiss.*, 1854, pls. 3–8), representing the marriage of Poseidon and Amphitrite. How far the merit belongs to Scopas of having introduced into Greek art the ideal types of those marine beings who personified the element of the sea, is unknown. In a temple of Apollo at Rome there was further a large composition, representing the slaughter of the children of Niobe, about the authorship of which there were two opinions,—the one ascribing it to Scopas, the other to Praxiteles. While this dubiety is itself proof that the two artists were rivals in the power of expressing pathos and suffering, there is a considerable probability that the composition in question was more adapted, of the two, to the genius of Scopas. Of this work there exists what is believed to be a more or less complete copy in the series of marble statues in the gallery of the Uffizi at Florence. The work is very uneven throughout, as might be expected in Roman copies; but the dramatic character of the action, and the powerful rendering of pain and suffering in the faces, still bespeak the style of the original sculptor, who, whether Scopas, Praxiteles, or another, was certainly an Athenian artist of the first half of the 4th century B.C. (Friederichs, *Bausteine*, i. pp. 230–246). Another example of the style of this period, in the combination of beauty with a lovable and touching expression of face, is the so-called statue of Leucothea, in the Glyptotheke of Munich, which there are grounds for assigning to Cephisodotus, the father, it would seem, of Praxiteles, who is recorded to have made for Athens a statue of Irene with the boy Plutus in her arms, which, as it appears on the coins of Athens, closely resembles the Leucothea. This Cephisodotus, standing as he did in the period between the old and the new Attic schools, seems to have shared the qualities of both, but to have inclined rather to the latter.

Praxiteles.

That Praxiteles was directly a pupil of Scopas is not proved even by the fact that he worked in the same artistic vein and spirit, with a result which rendered his style undistinguishable from that of the older master to the eyes of Roman connoisseurs. Still, it will be safe to assume that he was largely influenced in his youth by the then favourite sculptures of Scopas. The scene of his labours was mostly Athens and the neighbouring towns. That he accompanied Scopas to Halicarnassus to assist with the sculptures of the Mausoleum, as is stated, is probably true; but from the fact that elsewhere in place of his name occurs that of Timotheus, it has been inferred that he may there have abandoned his original intention, and confined himself to the execution of those statues for towns in that district of which we have records. About 340 B.C. he returned to Athens, and there remained till his death, studying, with Phryne as his model, the expression of sensual beauty in its highest type. Like Scopas, he had little taste for bronze in comparison with marble, with its surface finely sensitive to the most delicate modulation. Unsatisfied with even this, he endeavoured to soften the asperity of the marble in the crude parts by a process of encaustic, in which, or perhaps rather in the colouring of the draperies, he employed in difficult cases the contemporary painter Nicias (Pliny, *N. H.*, xxxv. 39, 122). That he was peculiar in thus tinting the marble, and an exception among other Greek sculptors, cannot be meant, in the face of so many instances as we now have of the application of the *circumlitio* in the remains of Greek sculpture and architecture (Semper, *Der Stil*, i. pp. 498 and 514). The fact, however, of his being mentioned in connection with it may be taken as a proof that the process was an exceedingly refined one, since his favourite subjects were those of youthful or feminine ideal beauty, in which it is to be supposed that the tints corresponding to those in nature would appear almost evanescent in their delicacy. Of his works, the number of which was unusually large, the most celebrated were—(1.) The marble statue of Aphrodite at Cnidus, of which the more or less modified copies, as the Venus of the Capitoline Museum and the Venus de Medicis, together with the ancient records, show that the goddess was represented standing nude at the moment when she has left her bath, and, being sensitive to the air, presses her left leg against her right, and looks towards the drapery which she has already laid hold of with her left hand. Originally commissioned by Cos, but declined on account of its nudity, this statue was replaced by another of Aphrodite, with which the marble statue in the Louvre, found in Melus in 1820, has frequently been compared. But before accepting it as an illustration of the type of Aphrodite by Praxiteles, or of the more highly praised figure of the goddess by Scopas, it is necessary to bear in mind that on a base found with it, which, though now lost, is vouched for on creditable authority, was inscribed the name of the artist, Alexandrus, son of Menides of Antioch, who must have lived after Alexander the Great (Friederichs, *Bausteine*, i. pp. 331–334). (2.) A statue of Aphrodite at Thespiæ; beside which was placed (3) a portrait statue of Phryne; and (4), a statue of Eros, in Parian marble, of which there are two accounts,—either that it was given by him to Phryne in token of his admiration, or that she contrived to obtain it by a ruse, and then dedicated it at Thespiæ. The figure of Eros was here not that of a boy, as in later art, but was taken from the period of youth at which love is purely ideal, and the whole being is pervaded by an elevating ardour. Apparently exhibiting the same refinement of youthful form was his statue known as the "Celebrated Satyr," in Athens. Of his Apollo Sauroctonus several copies of inferior merit exist. His statue of Artemis Brauronia at Athens had a mouth inviting to a kiss.

The ablest of the contemporaries of Scopas and Praxiteles were Bryaxis, Timotheus, and Leochares, of whom the last worked chiefly in bronze, and travelled over a wide field of conceptions, including deities, portraits, mythological and allegorical subjects. Another new type which belongs to this period is that of Serapis by Bryaxis. From the time of Philip and Alexander the Great, portrait statues furnished a large part of the occupation of sculptors, and in this they were not confined to living models, as we gather, for example, from the portraits of Sappho and Corinna by Apollodorus, a sculptor of this time,—a fact from which it may be inferred that portraiture was still inclined to idealism, though doubtless a strong tendency to realism had already set in.

Argive-Sicyonian school.

The development of the art of sculpture in the Argive Sicyonian school, corresponding to that just described in the second Attic school, was begun by the Corinthian Euphranor, whose principal study was directed with the view of modifying the hitherto canonical proportions of Polycletus, to suit the changed tastes with which he had probably become impregnated during his long stay in Athens. To this end he introduced a smaller head and a slimness of the arms and legs which gave a greater lightness to the figure, and which, under the hand of his follower Lysippus, became the favourite type of ideal athletic statues. Lysippus, a native of Sicyon, and originally employed as an ordinary worker in bronze, rose by dint of study to the position of a sculptor of the first order. Nor was the quality of his work more surprising than the quantity. About 1500 statues and groups in bronze were counted as having been produced in his workshop, and among them two at least of colossal size—the statue of Jupiter at Tarentum, 60 feet high, and that of Hercules in the same place. The masterpieces which he appears to have studied most were those of his townsman Polycletus. Like Euphranor, however, he was compelled to seek a new system of proportions,—to exchange the immovable dignity and repose by which the old masters suggested the possession of physical power, for new attitudes, in which the exercise of physical power should be made apparent by its effect on the body and on the face. The colossal frame of Hercules was a favourite study with Lysippus, for this reason especially, we presume, that of all the ancient heroes he was represented in the legends as bearing about with him always the effect of the arduousness of his labours. There was no gaiety or elasticity in his composition. A figure of an athlete in the act of scraping the sweat and dust from his body, Apoxyomenus, which enjoyed a high reputation in Rome, where it stood before the baths of M. Agrippa, has an additional interest for us in the fact that a marble copy of it still exists, which, though of inferior work, forms an admirable illustration of the statements re

FIG. 9.—Bronze figure, originally applied as a relief. Brit. Mus. Found at Tarentum. Apparently in the style of Lysippus.

garding the proportions adopted by Lysippus, viz., a small head and comparatively long slim arms and legs (*Monumenti d. Inst. Arch.* v. pl. 13; Friederichs, *Bausteine*, i. p. 286). That he was also equal to the times in the production of allegorical figures may be gathered from the description (see Overbeck, *Schriftquellen*, Lysippus) of his bronze statue of Cairus, a personification of what is vulgarly called the "nick of time." It remains to point out, with reference to the style of Lysippus, that he confined himself mostly to the rendering of male forms, and that in regard to the few female figures by him there is no mention of the charm of sensual beauty which characterised the second Attic school; nor, again, do we find that other characteristic of theirs, the expression of pathos, in the male figures by him. His *animosa signa* must be taken as expressing physical life—*anima*, not *animus*.

Among the remaining sculptures which belong to this period the most remarkable are—(1.) The sculptnres of the so-called Nereid monument discovered at Xanthus, in Lycia, by Sir Charles Fellows, and now in the British Museum. These sculptures consist of (*a*) a series of female figures in the round, about the size of life, wearing a thin long drapery through which the forms are entirely visible; (*b* and *c*) a broad and a narrow frieze, both representing battle scenes. While the design of the narrow frieze is singularly Assyrian in conception, that of the broader frieze and the statues in the round is purely Greek, at one time suggesting the style of the Parthenon sculptures, at another the refining and movement of the second Attic school (Fellows, *An Account of the Ionic Trophy Monument excavated at Xanthus*, London, 1848; W. W. Lloyd, *The Nereid Monument*, London, 1845). (2.) The reliefs on the monument of Lysicrates, a round building in Athens, popularly known as the Lantern of Demosthenes. The victory which it was erected to commemorate was gained in the year 334 B.C. The subject is Bacchus and his suite transforming the Tyrrhenian pirates into dolphins. The figures are powerful, but light of foot and tall. The unusually large spaces between the groups and figures is suggestive of the lonely distances on the sea-shore, and in this respect the frieze seems to encroach on the province of painting (*Marbles of the British Museum*, ix. pls. 22–26). (3.) A series of portrait sculptures, for which reference is made to Friederichs, *Bausteine*, i. pp. 290–308. The great bronze head (fig. 10) placed here may, on further consideration, require to be moved to an earlier period, though the pany carelessnesses in details which it exhibits seem at present to render such a step unadvisable.

Silver-smiths. Besides sculptors, otherwise famous, who applied themselves to toreutic art, there were others who made this their principal occupation. Of these we know Mys, who executed the designs on the shield of the bronze Pallas of Phidias on the Acropolis of Athens; and, more celebrated, Mentor, who worked chiefly on silver bowls and cups, for which fabulous sums were afterwards paid by Roman collectors. He must have lived before the time of Alexander the Great, since some of his works perished in the burning of the temple of Diana at Ephesus. Two other cælatores apparently of this period were Acragas and Bœthus.

Die-sinking. A branch of art allied to the cælatura is that of die-sinking and gem-engraving. Of the former the finest examples during this period are the silver coins of Syracuse, especially the decadrachms with the head of Arethusa on the obverse and a quadriga on the reverse. The presence of the engraver's name on many of these coins is testimony of the value attached to their work. From this source we know the engravers Cimon and Euænetus. Other names, such as Euclides, Eumenus, Eumelus, Phrygillus, and Sosion, also occur on smaller silver coins. With the exception of Athens, where the archaic type was preserved, there is a general feeling for beauty throughout the Greek coinage of this period, the specimens most deserving of

Fig. 10.—Colossal bronze head. Brit. Mus. Said to have been found at Satala in Armenia.

study being those of Arcadia, of the Opuntian Locri, of the Macedonian kings Philip and Alexander, of the Chalcideans of Thrace, of Cydonia in Crete, where the name of

Fig. 11.—Marble head of Alexander the Great. Brit. Mus. From Alexandria.

the engraver Neuantus occurs, and of Lesbus. **Gem-engraving.** In gem-engraving during this period the fame of Pyrgoteles is known, but of all the existing gems which bear his name it may be questioned whether one reflects adequately his style. It may be taken as certain that some of them are from his hand. He was the court engraver of Alexander the Great, whose portrait he made on an emerald. The marble head here given (fig. 11) shows a distinctly realistic tendency, compared with the head on the coins. Possibly the portrait of Alexander which appears on the coins of his successor Lysimachus was in some way drawn from the gem (Brunn, *Gesch. d. Griech. Künstler*, ii. p. 629). Among the few examples of gems that can be unhesitatingly assigned to this period is the chalcedony with the figure of a crane found in K tch, and now in the Hermitage, St Petersburg, bearing the signature of Dexamenus of Chius, ΔΕΞΑΜΕΝΟΣ ΕΠΟΙΕ ΧΙΟΣ (*Compte Rendu de la Comm. Arch. pour l'ann.* 1861, p. 147, pl. vi. 10).

In painting, the transition from the style of Polygnotus to that of the new school was again, as has been said, a transition from ethos to pathos, from character and noble bearing to beauty and effect. The change, as elsewhere, was in harmony with the spirit of the times; but of the steps by which it was brought about two deserve attention; the first is the exigencies of scene-painting, on which Sophocles, and, after his example, his older contemporary Æschylus, laid great value. In this direction the artist of the day was Agatharchus of Samus, who also wrote an account of the decorations executed by him, and by this led to the investigation of the principles of perspective in painting by Democritus and Anaxagoras. The second step was the gradation of light and shade and of colours introduced by Apollodorus, who for this service is regarded as the founder of the new school. At the door opened by Apollodorus entered Zeuxis, as he himself is reported to have said, into the sanctuary of art. Not that Zeuxis was directly a pupil of the older master. All that is known of their relations to each other consists of mutual compliments. That the charm of Zeuxis's popularity was in great part due to novelty of situation and effect might be inferred from the statement regarding his picture of a centauress suckling her young, the spectators of which forgot the painter in the subject. On the other hand, the story of his having constantly before his eyes five of the most beautiful maidens of the town of Croton while he was painting his figure of Helena, suggests that he must have been a close student of form and perhaps also of colour. His figures were of a large mould, as in the earlier school, and for this reason his heads and limbs appeared a little coarse to Roman connoisseurs accustomed to the elegance of a later time. In this direction a great step in advance was made by his contemporary Parrhasius of Ephesus, who like Zeuxis also lived some time in Athens, enjoying the society of Socrates, and vaunting his personal appearance as well as his artistic powers. The dominant faculty of drawing in Parrhasius led him to choose his subjects from male heroic figures, and led him also, it will be charitable and not without analogy to conjecture, to produce the immoral scenes with which his name is connected. From excellence in drawing and colouring the next step was towards a just conception of the subject on hand, and this step was taken by Timanthes, of the island of Cythnus. One of his great pictures was the tragic scene of the sacrifice of Iphigenia, in which the expression of sorrow was rendered with a masterly gradation, from the bystanders (Calchas, Ulysses, Ajax, and Menelaus) up to Agamemnon, in whom the deep grief of a father was expressed by his covering his face and turning it away from the spectator. This subject, with various modifications, and particularly with the absence of the gradation of grief among the bystanders, but still obviously preserving the profound pathos of a great original, occurs in Pompeian paintings, and on a Greek relief in the gallery of Florence (O. Jahn, *Archäol. Beiträge*, p. 378). Whether or not a resident at Ephesus, the centre of Asiatic painting, it is clear that Timanthes stood in close relation to the school there. Contemporary with the Asiatic school existed in Greece proper two schools of painting, of which the one, with its seat in Sicyon, seems to have studied most drawing and a system of form and proportions; while the other, centred at Athens, but including some Theban painters, looked rather to the expression of pathos and the emotions of the mind. The founder of the Sicyonian school was Eupompus (401–381 B.C.) It was, however, to his pupil Pamphilus that it owed most of its reputation, and became a school for practical instruction which attracted students from remote quarters. From his distinction in mathematics and geometry, and from the fact of his having introduced drawing as a general element of instruction for youth, it is inferred that his teaching was mainly directed to the reproduction of form. On the other hand, it is also known that his researches led to an improvement in the colours employed in encaustic painting, and further that this art was carried to its highest perfection by his pupil Pausias. In a middle position between the Sicyonian and Attic schools stood Euphranor the Corinthian, of whom as a sculptor mention has already been made. His subjects were of the higher grade of historical painting, being mostly large compositions of mythological scenes or historical events, of which an example was to be seen on the portico of Zeus Eleutherius in the Agora of Athens. In Thebes, where since the recovery of freedom from the Lacedæmonians a new impulse for art as well as politics had been felt, a school of painting was formed, apparently at first under the influence of that of Sicyon. At its head was Nicomachus, a son and pupil of Aristiæus. A greater fame was achieved by his son Aristides, as an example of whose work, Pliny (*N. H.*, xxxv. 36, 98) quotes a picture from the capture of a town in which a mother appeared mortally wounded, and with a harrowing expression of dread on her face lest the child clinging to her breast should suck blood instead of milk. His activity extended to portraiture and to *genre* subjects; but he worked by preference in the encaustic process, the credit of inventing which has been wrongly ascribed to him. Among the other painters of note who followed the manner of the second Attic school of sculpture there remains only Nicias, a son of Nicomedes of Athens, and a pupil of Antidotus, from whom he learned the extreme care of execution originally taught by Euphranor.

In the person of Apelles, the son of Pytheas, a native of Colophon, were combined, if we may judge from his reputation, all the best qualities of the hitherto existing schools of painting. It should, however, be remembered that what we know of him comes entirely from Roman and late Greek sources, and represents rather the taste of these times than a critical judgment on his works. He was a pupil of the otherwise unknown painter Ephorus of Ephesus, which town, already celebrated as a centre of painting, he adopted as his home. But so high was then the reputation of the Sicyonian school, headed by Pamphilus and Melanthius, that on completing his studies at Ephesus he repaired to Sicyon, either to see for himself or to profit by the fame of these masters. From Sicyon he proceeded, perhaps through the influence of Melanthius, to the court of Macedonia, where he was employed, first by Philip, and afterwards, under circumstances of the greatest intimacy, by Alexander, whom he accompanied as far as Ephesus on his expedition into Asia. Of the figures of deities painted by him the most renowned was that of Aphrodite Anadyomene, originally in the temple of Æsculapius in Cos, represented rising out of the sea, and wringing the wet out of her hair, with swelling bosom and an expression of desire in her eyes. A second figure of the goddess, also intended for Cos, remained unfinished at his death. Of personifications and allegorical figures or groups, such as delighted the age in which he lived, we have examples—of the former in his group of Bronte, Astrape, and Ceraunobolia; and of the latter in his famous picture of Calumny. Partly of this character also were his two pictures of Alexander grouped with Castor, Pollux, and Victory; and Alexander in a triumphal car, beside a personification of war, in the form of a captive with hands bound behind back and seated on armour. The execution of subjects of this nature, for which thought and reflection are mainly required as opposed to the poetic and spontaneously creative faculty of a true artist, has been urged as detracting from the greatness of Apelles, and to this extent, no doubt, he was subject to the weakness of his times. Like Correggio, with whom he has been compared, he lived at a time when the great creative spirit had passed away, and it remained for him, as for the Italian master, to discover the last resources of his art for the attainment of powerful effect and absolute finish simultaneously. To refine the harmony of his light and tones, as well as to protect his paintings from dirt, he employed a peculiar black glaze which broke the sharp contrasts of colours (Pliny, *N. H.*, xxxv. 97) required for such powerful effects as the appearance of Zeus hurling lightning. With regard to his colours little is known. The statement that he used only four (Pliny, *N. H.*, xxxv. 50, 92) may or may not be correct (Cicero, *Brut.*, 18). Of his mere skill we have an example in the figure of Hercules, afterwards in Rome, of which it was said that the face, though turned away from the spectator, was suggested almost as vividly as if it had been actually painted (Wustmann, *Apelles' Leben und Werke*, 1870). In technical skill Apelles confessed himself equalled by his contemporary Protogenes the Rhodian, claiming, however, as his own special superiority, that he knew when to stop. The fault of Protogenes was over-elaboration. On one painting he is said to have worked seven or eleven years, finishing it with four separate glazes to protect it from injury. Of the painters of this period there are still to be mentioned Antiphilus, a native of Egypt, and a pupil of Ctesidemus; Theon of Samus, who was praised for his happy choice of the right moment at which to seize an action; and Aetion.

Though the works of the masters of this period have wholly perished, there remain two sources from which some idea may be gathered of their manner,—first, a number of Pompeian paintings, which, though executed in a later age, and often intentionally varied from the originals, are still copies of the spirit and manner of the works of this time; and secondly, a large series of painted vases, which, though the production of inferior workmen, display a wonderful facility of execution, a splendour of glaze, and an application of colours which show that the example of the great painters had not been neglected. The figures stand out in red from the black ground of the vase; for the accessories, red, yellow, violet, black, blue, green, and gilding are employed. It is not, however, alone from their possession of certain traits which are assumed to have characterised the style of painting in this period that these vases are assigned to it. There exists a small but increasing series of painted vases which had been gained at the Panathenaic games at Athens, on several of which is inscribed the name of the archon for the year in which they were obtained. We have thus the exact years in which these vases were made, and at the same time specimens of the art of the time, from which a comparison is easily made with the larger series of undated vases (see Catalogue of the Vases of the British Museum).

Architecture.

With the close of the Periclean period in Athens the public desire for more temples seems to have ceased; so that the architecture of the period now before us is to be traced rather in works of utility, whether public or private. Of the former class are—(1), the stadium at Agræ for the athletic competitions at the Panathenaic festival; (2), the gymnasium; (3), the store-house at the Piræus, built to contain the equipments of 1000 ships. From private sources were (4), the temple of the Muses, said to have been erected by Plato, in the Academy; and (5), the choragic monument of Lysicrates, which is the only existing example of Athenian architecture of this time (Stuart, *Antiquities of Athens*, i. pls. 23–30). A greater architectural activity prevailed in the Peloponnesus. At Tegea was erected, under the direction of Scopas, a temple which scarcely yielded in splendour to that of Zeus at Olympia. The laying out and building of new towns which followed upon the recovery of freedom by Thebes under Epaminondas, gave abundant scope for architects. A remarkable example of this was Megalopolis in Arcadia, which was built in an elliptical form, on the principle laid down by Hippodamus of Miletus, and carried out in the Piræus, Thurium, and Rhodes. A more magnificent example of a new town erected in this period was Alexandria, founded by Alexander to be the first city of the world of which he was master, and built in that spirit by his favourite architect Dinocrates. The model of Alexandria was adopted by the successors of Alexander for the many new towns raised by them, as, for example, Antioch on the Orontes, the architect of which was Xenæus. The temples of Asia Minor erected in the time of Alexander may be judged from the ruins of those of Athene Polias at Priene, of Artemis at Magnesia on the Mæander, and of Artemis at Ephesus, of which last the site has lately been excavated, with the result of confirming the few existing statements regarding its dimensions and style. The Mausoleum at Halicarnassus, and the Nereid monument of Xanthus, are instances of temple architecture modified for the purposes of a tomb.

Fifth Period.

The conquests of Alexander had opened to the Greek gaze the East, gorgeous in its personal attire and equipments, and unlimited in its resources for the encouragement of personal vanity. Alexander appeared in Asiatic costume, and what became the monarch was shortly found becoming to the subject. Under his successors, in what is called the Macedonian, or, better, the Hellenistic period, the opulence and taste for luxury of the times led artists to aim at producing works conspicuous for picturesqueness; not, however, that picturesqueness which is born of a fine fancy, but that which originates in a studied effort to throw a gleam of romance over a plain historical incident. The creation of ideal types of deities ceased, and the production of allegorical figures, which had found acceptance in the preceding age, took its place. These figures were simply studies of character, and implied a faculty of observation which the existing portraits of this period on coins and in marble warrant us in estimating highly. To this, no doubt, was added a power of generalisation which enabled the artist to deduce a type from a number of individuals, as, for example, in the type of Gauls introduced by the school of Pergamus. In figures of deities or heroes the old types were retained. It was in portraiture that the essential characteristic of the time consisted. With art in this condition Græcia Capta enthralled her Roman captors, and the further development of this phase of art was transferred to Rome. For this reason we shall here follow the unusual plan of classing the Hellenistic and Roman art under one period.

The two principal schools of sculpture of the last period

School of Athens. are represented in this by the sons of the two great masters of each,—the Athenian school by the sons of Praxiteles,

FIG. 12.—Bronze statuette of a Philosopher. Brit. Mus. Found in harbour of Brindisi (*Brundusium*).

Cephisodotus and Timarchus, who worked together. The former appears to have been the more gifted of the two, if we may judge from the pains bestowed on certain statues of deities by him alone. Of their contemporaries little is known beyond that their chief occupation was in portrait sculpture. School of Sicyon. The traditions of the Sicyonian school were left in the hands of the sons and pupils of Lysippus, of whom the ablest was Euthycrates, who preserved the severity of the older schools in opposition to the tastes of his times. The effect of this upon his pupil Tisicrates led to so close a reproduction of the manner of Lysippus, that in many cases it was difficult to distinguish his work from that of the old master. In the same spirit, and with greater success, worked Eutychides of Sicyon, and Chares of Lindus in Rhodes. From the hands of Eutychides we know of a bronze statue of the river Eurotas, in which the mobility of water was finely suggested in the human form (Pliny, *N. H.*, xxxiv. 8, 78), and a highly-praised statue of Tyche (Pausanias, vi. 2, 7) for the town of Antioch, of which several copies exist, including a small one in silver in the British Museum. School of Rhodes. Chares is known mainly as the author of the bronze Colossus of Helius at Rhodes, a statue 105 feet high, which after standing a marvel to all for fifty-six or sixty-six years, was broken across the knees and thrown to the ground by an earthquake. The rising importance of Rhodes encouraged the foundation of a school of sculpture which adopted the manner of Chares, and aimed at effect by colossal proportions and picturesque situations. To this school belonged Apollonius and Tauriscus, the authors of a colossal marble group which has been identified with that in the museum of Naples, known as the "Farnese Bull," and representing Amphion and Zethus in the act of binding Dirce to the horns of a bull in presence of their mother Antiope, and, whether copy or original, an admirable illustration of the Rhodian school. The moment seized by the artists is one of profound pathos; but, justly deserved as the punishment of Dirce may have been, it is impossible to look upon it without pain. The same feeling, it may be imagined, was awakened in the spectator by the bronze group of Athamas seized with insanity after slaying his son Learchus, by Aristonidas, another artist of the Rhodian school. From the instances of subjects in which cruelty and deep emotion were combined, it has been argued that the group of Laocoön, which was the work of three Rhodian artists—Agesander, Athenodorus, and Polydorus—may properly be assigned to the Rhodian school of this period. On the other hand, it is argued by critics of seemingly equal competence, that the subject of the Laocoön is too harrowing for the Greek taste even then, and must have been executed under the influence of the favourite cruelties practised in the Roman circus. The decision between these two opinions is left entirely to taste, owing to the ambiguity of the words of Pliny. School of Pergamus. From Rhodes we pass to Pergamus, where, under the courtly influence of Attalus I. (241–197 B.C.) and Eumenes II. (197–159 B.C.), was formed a school of sculpture which derived a vigorous impulse as of a new life from the strange class of subjects it was called upon to undertake. It was called upon to glorify the decisive victory of Attalus over the Gauls (239 B.C.) by groups and large compositions of battle scenes, in which the first difficulty was to produce the type of these barbarians, and to carry it out consistently in the various attitudes and incidents of a battle; as, for example, in their dogged submission under captivity, or their grim expression under pain; or, again, the abject misery of their wives when a battle had been lost. Nor was Attalus content to adorn his own capital with artistic productions. To Athens he made a present of four groups representing battles between gods and giants, between Athenians and Amazons, between the Greeks and Persians at Marathon, and between his own army and the Gauls in Mysia, showing in each case the defeat of a barbarous race. The height of the figures was 3½ feet, and that there must have been a considerable number of them is clear from this, that the occurrence of Bacchus in the group of the Gigantomachia presupposes the existence of the other superior deities. Of the entire series nine figures have been identified in various museums (Engraved, *Monumenti dell' Inst. Arch.*, ix. pls. 19–21; Brunn, *Annali dell' Inst. Arch.* 1870, pp. 292–323; and *Bullettino*, 1871, pp. 28–31; Clarac, pl. 280, No. 2151); while to the same school belong the dying Gaul in the Capitoline Museum, known as the "Dying Gladiator," and the group of a Gaul and his wife in the Villa Ludovisi (Müller, *Denkmäler*, i. pl. 48, No. 218).

New Attic School. After the loss of national independence little remained for the Greeks to do but to profit by the liberal patronage of their Roman masters, whose cupidity in matters of art was by no means satisfied with carrying off as many as possible of the existing sculptures. The increased demand led to a new energy, of which Athens was at first naturally the centre, whence the term "New Attic" is applied to the sculpture of this period. As, however, this new energy was chiefly directed to the reproduction of the favourite types of the old masters, the result was not, as under other circumstances it might have been, the formation of a new school properly so called. At this time the principal sculptors were Polycles of Athens, his son Timarchides, his grandson Dionysius, and another Dionysius, all of whom, after earning a reputation by their work in various parts of Greece, appear to have followed Metellus to Rome, which now became the artistic centre of the world. Towards the end of the republic there lived in Rome a sculptor, Pasiteles, who, if not superior to the artists of the new Attic period in point of creative power, was certainly more gifted than they with skill and carefulness in the execution of his work, which ranged over statuaria, sculptura, and cælatura, including chryselephantine figures, for which a taste had revived. As, however, none of his works exist now, we can only judge of his manner by that of his pupil Stephanus, from whose hands we have the statue of Orestes in the Villa Albani (*Annali dell' Inst.* 1865, pl. D; Friederichs, *Bausteine*, i. p. 112). It is called Orestes from its resemblance to the male figure in the group of Orestes and Electra in Naples, with which, as an imitation of the archaic style, it may be compared. In both, however, it has been observed that the archaism is limited to the proportions, attitude, and general aspect, but that the details of anatomy have been worked in from the living model. This, which constituted the peculiarity of Stephanus, is assumed to have characterised the school of Pasiteles, first, because Stephanus, in an unusual manner, describes himself on the base of the statue as a pupil of Pasiteles; and secondly, because the same peculiarity to some extent is found in the group of Orestes and Electra in the Villa Ludovisi by the sculptor Menelaus, who again describes himself as a pupil of Stephanus (Friederichs, *Bausteine*, i. p. 427). Doubtless this affectation of archaism was to meet the taste of the time, for which also archaic works were collected from Greece. By the extreme elaboration of his work, Arcesilaus, who lived in Rome in Cæsar's time, obtained considerable fame, but, on the other hand, limited greatly his productivity. Of his two principal statues, the Venus Genetrix and the Felicitas, the latter was never finished. Copies of both exist, but they are of too mean a kind to suggest a proper estimate of the sculptor's merit. While in ideal sculpture the artists of this time were content to copy, with trifling varieties of detail, the works of the old masters, they appear to have disclosed considerable original talent in realistic sculpture, that is, in portraiture and in the historical representations with which triumphal arches and other like buildings were decorated, though here again they had models ready to hand in portraits, battle scenes, and triumphs of the Hellenistic period. A sculptor who had to celebrate a Roman victory over barbarians had his model in works of the same class by the school of Pergamus. When he introduced an ideal figure, as that of Victory writing on a shield, he adopted an old type. In the grouping of his figures there is this peculiarity, that they are frequently arranged on the principles of painting rather than of sculpture, and it is supposed that this originated in the earlier Roman custom of celebrating victories by paintings hung up in public places, which paintings appear to have been based on those of the Alexandrian period, and, at any rate, were sometimes executed by Greek artists. (For a thorough investigation of this subject see Helbig, *Campanische Wandmalerei*, Leipzig, 1873.)

Arcesilaus.

Silversmiths.

When public encouragement of art takes the form of a desire for reproduction from ancient masterpieces, it is natural that such minor arts as those of cælatura and gem-engraving should flourish. The production of silver vases adorned with subjects in relief had become a profitable occupation in the wealthy times of Hellenism. It was not, however, till the latter half of this period that truly fabulous sums came to be paid for work of this kind, in which Pasiteles and Arcesilaus, already mentioned as sculptors, achieved great success. Besides them we hear of Posidonius of Ephesus, Zopyrus, Pytheas, and Teucrus. Among the many existing examples of silver work of this period, one—a vase found in 1761 at the Porto d'Anzo, and belonging to the Corsini family—has been identified as a copy of the silver vase by Zopyrus representing the acquittal of Orestes before the Areopagus. The immense number of existing statuettes, vases, utensils of various kinds in bronze and silver, dating from this period, are evidence of its artistic activity, and at the same time of the closeness with which Greek models were adhered to.

Gem-engraving.

Under the influence of the luxurious tastes in the times of the Ptolemies, gem-engravers aimed mostly at effect, and to this end sought out specimens of onyx and sardonyx which from their own splendour would lend a charm to the work. A gem was now a thing to be worn flauntingly. Hence the chief examples of the art are the cameos, of which from the latter half of this period we have still some magnificent examples. Of these, the most important, artistically, is the large cameo, now in Vienna, representing, in a partly allegorical and partly literal fashion, the suppression of the Pannonian revolt by Tiberius and Germanicus (Müller, *Denkmäler*, i. pl. 69, No. 377). Larger and richer in figures, but much inferior in work, is the cameo in the cabinet of medals in Paris (Müller, *ibid.* No. 378). Besides producing cameos for personal ornament, the gem-engravers of this period were also employed on the production of drinking-cups of onyx and other precious stones, of which the tazza Farnese in Naples is the best existing example (*Mus. Borb.*, xii. pl. 47). When stones were too costly, glass was used, as in the famous Portland vase in the British Museum, and in numerous cameos. Compared with the cameo-engravers, who, as if conscious of the inferiority of their work, withheld their names from it, the engravers of intaglios very frequently asserted their merit by adding their names. Among the names thus handed down are those of Dioscurides, his son Eutyches, Athenion, Protarchus, Solon, Euodus, and others of lesser note.

Painting.

In the history of painting during this period few names of importance occur. In the earlier part of it the traditions of the school of Sicyon were maintained by Nealces, from whose hands we know of a picture of Venus, and of a naval engagement between Persians and Egyptians on a river which was localised as the Nile, by the presence of a crocodile and an ass drinking at the edge; and Timanthus, who painted a battle between the troops of Aratus and the Ætolians. In the Athenian school, Athenion, though dying young, produced some works which were favourably compared with those of the older master, Nicias. About this time the production of painted vases, driven out of fashion by vases in silver and other metals, so far ceased to attract skilled workmen, that it can hardly be fair to regard the large number of so-called Apulian vases belonging to this period as evidence of the contemporary style of painting. The ornament and the colours are always florid, the figures are drawn mechanically as from a set design, and the dimensions are very frequently large. According to the theory advanced by Brunn (*Probleme in der Gesch. der Vasenmalerei*), almost the whole of the vases found in Italy with black figures on red ground, which previously were considered archaic, were produced about this time, and are but feeble imitations of the early style made to please the Roman taste for archaic work. As to the general feebleness that prevails among them there can be little question. It remains to be seen, however, whether Brunn has not placed them at too late a period.

Painting in Italy.

With the scanty records of painters, and the depreciatory remarks in regard to the art of their time made by Pliny and Petronius, we have to compare the immense series of paintings from this period still existing in Italy, and particularly those of Pompeii and Herculaneum, an examination of which will show that the painters then, like the contemporary sculptors, drew their inspiration, and apparently to a tolerably close extent their models, from more ancient works. Had they been gifted with original genius, they could not have excluded, when painting landscapes, the views of the immediate neighbourhood; and yet on all the walls of Pompeii or Herculaneum there is perhaps not more than one subject which can be positively identified as local. Nor would they have avoided so systematically as they have done subjects from the national Roman legends, which were then in high favour, and attracted poets like Virgil and Ovid. But while a complete dearth of imaginative power may be denied them, these painters were possessed of a fine eye for pictorial effect, and of a refined taste in the management of their colours (Helbig, *Wandgemälde Campaniens*, to which is prefixed an elaborate inquiry into the technical processes employed; and Helbig, *Campanische Wandmalerei*, 1873, where the sources from which these painters drew are fully pointed out).

Mosaics. Closely allied to painting is the art of mosaic-working, which, though occasionally employed for the pavements of the earlier temples, as in the pronaos of the temple at Olympia (*Expédition de la Morée*, i. pl. 63), did not till after the time of Alexander assume an importance which entitled it to be ranked as an independent art. The first mosaic artist of consequence whom we hear of is Sosus of Pergamus, celebrated as having introduced the practice of decorating floors of houses with imitations of characteristic objects, such, for example, as the accompaniments of a feast in a dining-room. From Pergamus, Ephesus, Alexandria, and the chief towns of the Macedonian period, the art was afterwards transferred to Rome, where the numerous villas and palaces furnished it with abundant occupation. As an example of the work of this later time we have the large mosaic found on the Aventine in 1833, and now in the Lateran, which bears the name of Heraclitus as its author, and which, with its representations of all manner of remains from a feast, is an illustration of the class of subjects introduced by Sosus. We still possess a splendid example of their rendering of historical subjects in the mosaic found in 1831 in the Casa del Fauno at Pompeii, representing a battle between Alexander and the Persians (Müller, *Denkmäler*, i. pl. 55, No. 273).

Architecture in Greece. What was said of the progress of architecture at the close of last period should be here borne in mind, as it continues to apply to the first half of the period now before us. While the building of Alexandria supplied a model and an impulse, which the successors of Alexander availed themselves of, in the construction of new towns, the example of boundless luxury, in the decoration of even temporary monuments, which was set by Alexander in the erection of a funeral pyre for Hephæstion in Babylon, was also eagerly followed by his successors. From the work of Callixenus on Alexandria we have (Athenæus, v. p. 196) a description of the tent erected by Ptolemy Philadelphus for a Dionysiac festival, and of the splendid colossal barge of Ptolemy Philopator on the Nile (*ibid.* p. 204, *d*). Still more magnificent and stupendous in its dimensions was the ship of Hiero of Syracuse, with its granaries, dwelling-houses, towers, gymnasium, and park, for the construction of which Archimedes and the Corinthian Archias were employed. Greece proper, however, shared little in this prodigality. Thebes was, indeed, restored after its destruction by Alexander; and Athens, still the eye of Greece, obtained many marks of favour from the princes of the time, who sought to identify their names with her glory by erecting public monuments of various kinds.

Architecture in Rome. The presence of countless specimens of Greek art in Rome, carried off by plunderers like L. Mummius, produced a general craving for Greek architecture also. The first step in this direction was taken by Q. Cæcilius Metellus, who brought a Greek architect, Hermodorus of Salamis, to Rome to build a temple to Jupiter Stator in the pure Greek style. The public favour with which this was viewed may be gathered from the fact, that shortly after we find D. Junius Brutus employing Hermodorus to build a temple to Mars. Of the Roman architects who during the republic adopted the Greek style, the most distinguished were Cossutius and C. Mutius. The Greek had either supplemented or become blended with the native Roman architecture when the extraordinary activity in building, of which Pompey and Cæsar were the leaders, set in, not only in Rome, but throughout the provinces of the empire. The building of temples and monuments, which under Augustus had been the chief occupation of architects, gave way under his immediate successors to constructions of a more useful and sometimes of a colossal type, such as bridges, canals, aqueducts, and harbours. The enlargement of the imperial palaces on the Palatine, particularly the construction of the golden house of Nero, gave scope to the boldness of design and extravagance of execution possessed by the architects Celer and Severus. In the following times those of Vespasian, Titus, and Domitian were characterised by a series of buildings which had not their equal in the architectural history of Rome, as, for example, the Colisseum, a building erected to contain 87,000 spectators, and still in its ruins the most striking monument of imperial Rome. While the chief interest of Trajan was in the construction of roads, bridges, and harbours, his successor, Hadrian, was not only himself ambitious as an architect, but gave a new impetus to the erection of splendid buildings throughout the empire. From this time onward Roman architecture began to sink rapidly, its original tendency to florid decoration obtaining more and more free rein, till finally discrimination was abandoned. The ruins of Palmyra and Baalbec (R. Wood, London, 1827), the arch of Severus, the baths of Caracalla and Diocletian, and the arch of Constantine, are evidence of this.

The authorities on CLASSICAL ARCHÆOLOGY are cited in the text.

ARCHANGEL, a government of European Russia, lying between lat. 61° and 71° N., and long. 29° and 68° E. It is bounded on the N. by the White Sea and Arctic Ocean, on the W. by Finland and Olonetz, on the S. by Vologda, and on the E. by the Ural Mountains. It comprehends the islands of Nova Zembla, Waigatz, and some others. Its area is estimated at 286,739 square miles, and its population in 1867 was 275,779. The climate is for the greater part of the year intensely cold. That part of Archangel which lies within the arctic circle has a very desolate and sterile aspect, presenting little to the eye but extensive plains of sand and moss. The winter is long and severe, and even in summer the soil is frozen at a little depth below the surface. The rivers are closed in September, and scarcely thawed before July. South of the arctic circle the greater part of the country is covered with immense forests, with extensive lakes and morasses, while other parts afford excellent pasturage. The spring is moist, with cold, frosty nights; the summer, a succession of long foggy days; the autumn moist; and the rivers are closed from October to April. The northern districts are incapable of being cultivated, and the inhabitants support themselves by fishing and the chase. In the southern districts considerable quantities of hemp and flax are raised, but grain crops are little attended to, and the bark of trees is ground with corn to eke out the scanty products of the harvest. Potatoes are grown as far north as 65°. The principal wealth of the government consists in its immense forests, furnishing materials for shipbuilding, which is carried on to a considerable extent. The horses and cattle are diminutive, except in the district of Kholmogory, where excellent cattle are reared. The calves are sent to the St Petersburg market, where the veal is especially prized. Gold is found in the circle of Cola, naphtha and salt in those of Kem and Pinega, and coal, or rather lignite, in several places in Mezen. The preparation of pitch and tar is an active branch of industry; and in the districts around Archangel coarse linens are manufactured to a considerable extent, as well as cordage, mats, leather, tallow, turpentine, and potash. This government is divided into eight circles, viz.—Archangel, Shenkursk, Mezen, Cola, Onega, Pinega, Kholmogory, and Kem. Its chief rivers are the Onega, Pinega, Dwina, Mezen, Petshora, and Ousa. Sulphurous springs are found in the circles of Kholmogory and Shenkursk. The population was originally Finnish, but it is now chiefly Russian, with some Samoides and Laplanders.

ARCHANGEL, the chief town of the Russian government of the same name, is situated at the head of the delta of the Dwina, on the right bank of the river, in lat. 64° 32′ 8″ N., and long. 40° 33′ E. As early as the 10th century the Norsemen had commercial settlements in the district; but the modern town may be said to date from the visit paid by the English voyager, Chancelor, to the monastery of St Nicholas, whither he was driven by stress of weather in 1553. An English factory was soon after erected there by consent of Ivan II., and in 1584 a fort was built, and a town gradually gathered round it, which received the name of *Arkhangelskoi-Gorod*, from a monastery dedicated to the archangel Michael. The town long remained the only seaport of Russia, and enjoyed remarkable prosperity. Czar Boris Godunoff (1598–1605) made the trade through Archangel to Moscow open to all nations, and Holland and Germany took advantage of the permission. In 1655 the exports amounted to 600,000 roubles. In 1668 the great bazaar, or "*Gostinnoi-Gorod*," a strong building of stone, was commenced at the command of Alexei Michaelovich, and employed the labour of thousands of Tatar prisoners for 16 years. In 1693–94 Peter the Great visited the town, which was then at the height of its prosperity; the average annual value of the exports from 1691–1700 to England alone amounting to £112,210. When, in the beginning of the 18th century the czar was establishing St Petersburg, he did all he could to divert the population and prosperity of Archangel to the new metropolis, causing many of the wealthier inhabitants to remove, and imposing heavy taxes on the commerce. As a natural consequence, the northern city declined. In 1762 it received the same immunities as St Petersburg, and since that time has gradually recovered its former prosperity. It is the seat of an archbishop and of a civil and a military governor, and has one Protestant and ten Greek churches, an ecclesiastical seminary, a gymnasium, academies for navigation and engineering, a naval hospital, and a Government bank. The manufactures are linen, leather, canvas, cordage, mats, sugar, and beer. The exports are flax, flax-tow and codilla, oats, linseed, wheat, deals, tar, pitch, rosin, mats, beef and pork, calf and seal skins, train-oil, cordage, feathers, and linseed cakes. Flax, in large quantity, is used in the spinning factories in the interior. The imports are coal, oil, wine, coffee, sugar, tea, logwood, furs, lead, salt, and fish. The total value of the exports in 1874 amounted to £1,234,390 in 472 ships, of which 62 were steamers and 220 coasting vessels, a large proportion being carried to Great Britain. The coasting trade between Archangel and Norwegian Finmark is extensive. The domestic trade consists chiefly in meat, fish, train-oil, game, and furs. By river and canal Archangel is in connection with a large part of European Russia, and a telegraph line unites it with St Petersburg. The harbour is at the island of Solombaly, about a mile below the town, and is open only from June to October. A bar at the mouth of the Dwina, with only 13 or 14 feet of water, obliges vessels of greater draught to load and unload outside by means of lighters. About 12 miles below the town there is a Government dockyard, with slips for building vessels, and also some warehouses belonging to merchants in the city. The best season of the year in Archangel is from the middle of June to the middle of August. After that period the nights become cold; and in September it is often stormy. The shortest day has only 3 hours 12 minutes, the longest 21 hours 48 minutes. Population in 1867, 19,936.

ARCHBISHOP, the title of a church dignitary of the first class. Archbishops were not known in the church before the 4th century after Christ, when the term "Archbishop" was introduced in the East as a title of dignity, which did not necessarily imply any superiority of jurisdiction over a bishop. Athanasius, bishop of Alexandria, appears to have been the first who made use of the term in applying it as a mark of personal honour to Alexander, his predecessor in the see of Alexandria, and Gregory Nazianzen applied the term in like manner to Athanasius. In the following century the title of archbishop seems to have been applied to the bishops of the more important sees, as the names of several archbishops are recorded in the list of church dignitaries, who were assembled in the Council of Chalcedon in 451 A.D. In the Latin Church the title was hardly known before the 7th century after Christ. Isidore of Seville (Hispalensis) is the first writer who speaks of archbishops, distinguishing them as a class from patriarchs, metropolitans, and bishops. Archbishops in the present day are for the most part either patriarchs or metropolitans; but an archbishop is not necessarily a patriarch or a metropolitan, and there are metropolitans who have only the title of bishops. The ecclesiastical government of the Church of England is divided between two archbishops,—the archbishop of Canterbury, who is primate of all England and metropolitan of the province of Canterbury, and the archbishop of York, who is primate of England, and metropolitan of the province of York. The jurisdiction of the archbishop of Canterbury as primate of all England extends in certain matters into the province of York. He exercised the jurisdiction of *legatus natus* of the Pope throughout all England before the Reformation, and since that event he has been empowered, by 25 H. VIII. c. 21, to exercise certain powers of dispensation in cases formerly sued for in the court of Rome. Under this statute the archbishop continues to grant special licences to marry, which are valid in both provinces; he appoints notaries public, who may practise in both provinces; and he grants dispensations to clerks to hold more than one benefice, subject to certain restrictions which have been imposed by recent statutes. The archbishop also continues to grant degrees in the faculties of theology and law, which are known as Lambeth Degrees. His power to grant degrees in medicine, qualifying the recipients to practise, has been practically restrained by 21 and 22 Vict. c. 90. The province of Canterbury consists of twenty-one dioceses—St Asaph, Bangor, Bath and Wells, Canterbury, Chichester, St David's, Ely, Exeter, Gloucester and Bristol, Hereford, Lichfield, Lincoln, Llandaff, London, Norwich, Oxford, Peterborough, Rochester, Salisbury, Winchester, and Worcester. The bishops of the above-mentioned dioceses constitute the Upper House of Convocation of the prelates and clergy of the province of Canterbury. The archbishop is president *ex officio* of this Convocation, which is summoned by him pursuant to a royal writ whenever the Parliament is called together (see CONVOCATION), and it is prorogued and dissolved whenever the Parliament is prorogued or dissolved.

The archbishop of Canterbury exercises the twofold jurisdiction of a metropolitan and of a diocesan bishop. As metropolitan he is the guardian of the spiritualities of every vacant see within the province, and he presents to all benefices which fall vacant during the vacancy of the see, and through his special commissary exercises the ordinary jurisdiction of a bishop within the vacant diocese. He exercises also an appellate jurisdiction over each bishop, which in cases of licensed curates he exercises personally under 1 and 2 Vict. c. 106; but his ordinary appellate jurisdiction is exercised by the judge of the provincial court of appeal, which from the circumstance of its having been held in former days in the church of St Mary of the Arches (Bow Church), which was a peculiar of the archbishop, has come to be called the Arches Court of Canterbury. The judge of this court, who is appointed by the archbishop, is properly styled the Official Principal of the Arches Court, but he is commonly called the Dean of the Arches, from a peculiar jurisdiction, now abolished, which he formerly exercised in the name of the archbishop over fifteen churches in the diocese of London. The archbishop had formerly exclusive jurisdiction in all causes of wills and intestacies, where parties died having personal property in more than one diocese of the province of Canterbury, and he had concurrent jurisdiction in other cases. This jurisdiction, which he exercised through the judge of the Prerogative Court, has been transferred to the Crown by 20 and 21 Vict. c. 77. The Arches Court was also the court of appeal from the consistory courts of the bishops of the province in all testamentary and matrimonial causes. The matrimonial jurisdiction has been transferred to the Crown by 20 and 21 Vict. c. 78. The Court of Audience, in which the archbishop presided personally, attended by his vicar-general, and sometimes by episcopal assessors, has fallen into desuetude. The vicar-general, however, exercises jurisdiction in matters of ordinary marriage licences and of institutions to benefices. The Master of the Faculties regulates the appointment of notaries public, and all dispensations which fall under 25 H. VIII. c. 21.

The first archbishop of Canterbury was Augustine the monk, whose preaching converted King Ethelbert. Augustine was consecrated a bishop for England in 597 A.D., and received the *pallium*, which is the distinguishing mark of the metropolitan's office, from Gregory the Great in the following year. He was subsequently constituted *legatus natus* of the apostolic see, and his successors enjoyed various *jura regalia* by grant from the Crown. They had also precedence over all subjects of the Crown not of royal blood, and the archbishop still retains such precedence over every Peer of Parliament. It is also his privilege to crown the kings and queens of England. He is entitled to consecrate all the bishops within his province, and was formerly entitled, upon consecrating a bishop, to select a benefice within his diocese as his option for one of his chaplains, but this practice has been indirectly abolished by 3 and 4 Vict. c. 111, § 42. He is entitled to nominate eight chaplains, who had formerly certain statutory privileges, which are now abolished. He is *ex officio* an ecclesiastical commissioner for England, and has by statute the right of nominating one of the salaried ecclesiastical commissioners.

The archbishop exercises the ordinary jurisdiction of a bishop over his diocese through his Consistory Court at Canterbury, the judge of which court is styled the Commissary-General of the city and diocese of Canterbury. The archbishop holds a visitation of his diocese personally every three years, and he is the only diocesan who has kept up the triennial visitation of the dean and chapter of his cathedral.[1]

The province of York consists of six dioceses in England, Carlisle, Chester, Durham, Manchester, Ripon, and York, to which may be added the diocese of Man, which was annexed under that title by 33 Henry VIII. c. 31, to the province of York. The latter diocese has been entitled in recent Acts of Parliament the diocese of Sodor and Man, and it is now generally so designated. The bishops of the above seven dioceses constitute the Upper House of Convocation of the prelates and clergy of the province of York, of which the archbishop is *ex officio* president, and which is convened, prorogued, and dissolved under the same conditions as the Convocation of the province of Canterbury.

The archbishop of York has immediate spiritual jurisdiction as metropolitan in the case of all vacant sees within the province of York, analogous to that which is exercised by the archbishop of Canterbury within the province of Canterbury. He has also an appellate jurisdiction of an analogous character, which he exercises through his provincial court, whilst his diocesan jurisdiction is exercised through his consistorial court, the judges of both courts being nominated by the archbishop. His grace's ancient testamentary and matrimonial jurisdiction has been transferred to the Crown by the same statutes which have divested the see of Canterbury of its jurisdiction in similar matters.

The first archbishop of York was Paulinus, to whom Pope Honorius I. sent the *pallium* in 634 A.D. in fulfilment of the intention of Pope Gregory the Great. The successors of Paulinus exercised metropolitan jurisdiction over the bishops of Scotland until the latter part of the 15th century, when Pope Sixtus IV. raised the bishopric of St Andrews into an archbishopric, and constituted the archbishop of St Andrews primate of all Scotland, and *legatus natus* of the apostolic see in Scotland. The archbishop of York takes precedence over all subjects of the Crown not of royal blood, next to the lord high chancellor of England, who is preceded by the archbishop of Canterbury. He is *ex officio* an ecclesiastical commissioner for England.

The first archbishop of St Andrews was Patrick Graham, who successfully disputed the superiority of the see of York, and was constituted metropolitan over all the diocesan bishops of Scotland in 1474 A.D. His successors continued to exercise metropolitan jurisdiction throughout Scotland until 1491 A.D., when Pope Innocent VIII. sent the *pallium* to the bishop of Glasgow, and constituted him metropolitan over the dioceses of Argyle, Dunblane, Dunkeld, Galloway, and Glasgow, whilst the archbishop of St Andrews continued to exercise metropolitan jurisdiction over the dioceses of Aberdeen, Brechin, Caithness, Edinburgh, Moray, Orkney, Ross, and St Andrews, until the Episcopal form of church government ceased to have any legal authority in Scotland.

[1] The Court of Peculiars is no longer held, inasmuch as the peculiars have been placed by Acts of Parliament under the ordinary jurisdiction of the bishops of the respective dioceses in which they are situated.

The Church of Ireland was united, by the fifth article of the Act for the Union of Ireland with Great Britain, into one Protestant Episcopal church with the Church of England, and it had at that time four archbishops, who took their titles from Armagh, Dublin, Cashel, and Tuam. The archbishop of Armagh was primate of all Ireland and metropolitan of the province of Armagh, and the other archbishops were primates of Ireland and metropolitans of their respective provinces. By 3 and 4 Will. IV. c. 37, and 4 and 5 Will. IV. c. 90, the metropolitans of Cashel and of Tuam were reduced to the status of diocesan bishops, and, with the then existing eighteen bishops, were reduced in number to ten bishops by the consolidation of their dioceses, so that each of the two archbishops had five diocesans subject to his metropolitan jurisdiction. By 32 and 33 Vict. c. 42, the union between the Churches of England and of Ireland was dissolved, and the Church of Ireland has ceased to be established by law. (T. T.)

ARCHDEACON. The office of archdeacon is of ancient institution in the Christian church, as archdeacons are mentioned in the 4th century after Christ. The title was originally given to the chief deacon in each diocese, who had the charge of the temporal affairs of the church, and the supervision of all matters which appertained to the order and decency of divine service. In the course of time the archdeacons encroached upon the episcopal jurisdiction, but their encroachments were restrained in England by the Council of London, 1237 A.D, and in other countries by ecclesiastical councils held in the 13th and 14th centuries.

There was originally one archdeacon in every English diocese, but there are at present by statute 6 and 7 Will. IV. c. 97, at least two archdeaconries in each diocese, and in some dioceses there are four archdeacons. The archdeacons are appointed by their respective bishops, and they are by 3 and 4 Vict. c. 27, § 27, required to have been six full years in priest's orders. The functions of the archdeacon are in the present day ancillary in a general way to those of the bishop of the diocese. The archdeacon is sometimes styled "Oculus Episcopi," and it is his especial duty to inspect the churches within his archdeaconry, and to hold annual visitations of the clergy and churchwardens of each parish, for the purpose of ascertaining that the clergy are in residence, of admitting the newly-elected churchwardens into office, and of receiving the presentments of the outgoing churchwardens. It is his privilege to present all candidates for ordination to the bishop of the diocese. It is his duty also to induct the clergy of his archdeaconry into the temporalities of their benefices after they have been instituted into the spiritualities by the bishop or his vicar-general. Every archdeacon is entitled to appoint an official to preside over his archidiaconal court, from which there is an appeal to the Consistory Court of the bishop. The archdeacons are *ex officio* members of the Convocations of their respective provinces. See CONVOCATION.

It is the privilege of the archdeacon of Canterbury to induct the archbishop and all the bishops of the province of Canterbury into their respective bishoprics, and this he does in the case of a bishop under a mandate from the archbishop of Canterbury, directing him to induct the bishop into the real, actual, and corporal possession of the bishopric, and to install and to enthrone him; and in the case of the archbishop, under an analogous mandate from the dean and chapter of Canterbury, as being guardians of the spiritualities during the vacancy of the archi-episcopal see. (T. T.)

ARCHDUKE, a title borne during the Middle Ages by the dukes of Austria, Lorraine, and Brabant. All three archduchies having devolved to the imperial family of Austria, the sons of that house are styled archdukes, and the daughters archduchesses.

ARCHELAUS, a Greek philosopher, was a native most probably of Athens, though some say he was born at Miletus. Nothing is known of his life, but as he was a pupil of Anaxagoras, he must have lived about 450 B.C. By several writers he is said to have been the teacher of Socrates, but this report has no support from Plato, Aristotle, or Xenophon, and probably has no foundation save the wish to connect Socrates closely with preceding philosophy. So far as the opinions of Archelaus are known, he seems to have followed with some deviations his master, Anaxagoras. With him he admitted a primitive matter, consisting of infinite particles similar in nature to the bodies formed from them. He further admitted a ruling mind; but he attempted to overcome the dualism of Anaxagoras, and in so doing, more nearly approached the older Ionic physical philosophers. He thought that matter was mingled with mind, and identified the primitive matter with air. His first principle was thus air endowed with mind. Out of this air, by the processes of thickening and thinning, arose cold and warm, or water and fire, the one passive, the other active. From the action of fire on water are formed the atmosphere and the mud, out of which the earth and the heavenly bodies are developed. Living, organised beings, at first of a low type, spring out of this mud, and gradually the races of animals are formed. Man is superior to other beings by his moral and artistic powers. To Archelaus are attributed some ethical doctrines, such as, that right and wrong are not by nature but by custom. This is a well-known proposition of his contemporaries, the Sophists, and in all probability it is attributed to Archelaus erroneously. Ethical teaching was no doubt ascribed to him merely to explain the completely ethical character of the philosophy of his supposed pupil Socrates. No fragments of Archelaus remain; his doctrines have to be extracted from Diogenes Laërtius, Simplicius, Plutarch, and Hippolytus.

ARCHELAUS, natural son of Perdiccas, king of Macedonia, seized the throne in 413 B.C., after having murdered his uncle, his cousin, and his half brother, the legitimate heir. His reign was remarkable for the many improvements he introduced. He fortified cities, constructed roads, and thoroughly organised the army. He endeavoured to spread among his people the refinements of Greek civilisation, and invited to his court many celebrated men of the time—as Zeuxis, Timotheus, Euripides, and Agathon. In 399 B.C. he was killed by one of his courtiers, Craterus; according to some, designedly, according to others, accidentally while engaged in hunting.

ARCHELAUS, a general of Mithridates, commanded his army in the war against the Romans. He was sent into Greece with an army of 120,000, and after three days' fighting with Bruttius Sura, occupied the Piræus. Here he was attacked by Sulla, and after a hard struggle was compelled to withdraw into Bœotia. Sulla followed, and at Chæronea, 86 B.C., completely routed him. A fresh army was sent by Mithridates, but at Orchomenos, after a two days' battle, Archelaus was again defeated. Peace was soon afterwards concluded, but as Archelaus found that he had incurred the displeasure of Mithridates, he fled over to the Romans, by whom he was well received. He is not heard of again in history, but several of his descendants of the same name held high posts under Pompey, Antony, and Augustus.

ARCHELAUS, son of Herod the Great, had the kingdom of Judæa left him by the last will of his father, though a previous will had bequeathed it to his brother Antipas. He was proclaimed king by the army, but declined to assume the title until he had submitted his claims to Augustus at Rome. Before setting out, he quelled with the utmost cruelty a sedition of the Pharisees, slaying nearly 3000 of them. At Rome he was opposed by Antipas and by many of the Jews, who feared his cruelty, but Augustus allotted to him the greater part of the kingdom with the title of Ethnarch. He married Glaphyra, the widow of his brother Alexander. This violation of the Mosaic law and his continued cruelty roused the Jews, who complained to Augustus. Archelaus was deposed (7 A.D.) and banished to Vienne. The date of his death is unknown.

ARCHELAUS, son of Apollonius, a sculptor of Priene, is celebrated by his bas-relief representing the apotheosis of Homer. From the style of the work, and from its having been found in the palace of the Emperor Claudius at Bovillæ, it may be concluded that it belongs to the 1st century of the Christian era. For some time the bas-relief was in the possession of the Colonna family, but in 1819 it was purchased for £1000, and placed in the British Museum.

ARCHENA, a town of Spain, in the province of Murcia, of interest on account of its hot mineral springs and old Roman baths. It is fairly built, and contains a palace of the Corbora family. Population about 2000.

ARCHERY, the art or exercise of shooting with a bow and arrow. The origin of the bow as an instrument of war is lost in obscurity. With all the ancient peoples, both civilised and barbaric, the bow was a favourite weapon, and skill in the use of it was regarded by the Scythians as a princely accomplishment. The Greeks and Romans employed archers to draw the enemy into action, and the exploits of the ancient Egyptians rivalled those of the archers of the Middle Ages.

There is no record of the use of the bow in France until the reign of Charlemagne, in the beginning of the 8th century, although we have evidence that in England both the Anglo-Saxons and the Danes employed it in the chase, as well as in battle against the primitive inhabitants of England, many years before the Conquest. The probability is that it was first introduced as a military weapon into Britain by the Romans; but it was under the Norman rule that the practice of archery in this island was not only greatly improved, but generally diffused throughout the country, so that England soon became famous for its archery, and her archers took precedence of those of every other nation. To preserve this superiority by constant practice appears to have been the study of many of our monarchs; and numerous statutes for enforcing and regulating the use of the bow among the people were enacted from early times until after the invention of fire-arms. Many laws were also made for securing the presence in distant and obscure parts of the country of persons skilled in the manufacture of bows and all the apparatus appertaining to archery, for guarding against fraud by those artificers, and also for the procuring of a constant supply of bow-staves from abroad. These laws appear to have been absolutely necessary, for in the olden time the English chiefly depended for their success in battle upon the bravery and expertness of their archers, whose appearance in the field generally led to success. William the Conqueror is reputed to have been so admirable an archer that few could bend the bow he used, and his victory at Hastings was certainly due to the skill and intrepidity of his archers. Richard I. performed great exploits with his archers in the Holy Land, where, according to Gibbon, 300 archers and 17 knights, headed by the king, sustained the charge of the whole Turkish and Saracen army. It was in his reign that the renowned Robin Hood flourished in Sherwood Forest. Edward II. levied a company of "Northumbrian archers" in the year 1314, for the invasion of Scotland.

The battles of Cressy and Poitiers were gained by the English archers in the years 1346 and 1356 respectively. Edward III. was extremely jealous of the honour of the bow, and anxious that its glory should be maintained. In the early part of his reign it was ordered that most of the sheriffs of England should each provide 500 white bows and 500 bundles of arrows for the then pending war with France. In the following year this order was reissued, with the difference that the sheriff of Gloucester should furnish 500 painted bows in addition. This king embodied a company of soldiers, whom he called the "Archers of the Guard." Edward III. also, in 1363, commanded the general practice of archery on Sundays and holidays by the people in lieu of the ordinary rural pastimes, which were forbidden on pain of imprisonment. In this reign the price of bows was regulated by Government; a white bow was 1s., a painted bow 1s. 6d., a sheaf (24) of sharp arrows 1s. 2d., and a sheaf of blunt arrows 1s. Richard II., in 1392, directed that none of his servants should ever be unfurnished with bows and arrows, and that they should avail themselves of every opportunity of practising archery. At the same date an Act of Parliament compelled all persons employed as servants to shoot with bows and arrows on Sundays and other holidays. In the year 1402 the English archers won the battle of Homildon; and in 1403, at the battle of Shrewsbury, where Hotspur was slain, the most terrible havoc was created by the archers on both sides. In the reign of Richard III., it was enacted that for every ton of Malmsey or Tyne wine brought into England, ten good bow-staves should also be imported, under penalty of 13s. 4d. for every deficient stave; and to encourage the import of bow-staves, those above 6½ feet long were freed from duty.

For the manufacture of bows yew was generally preferred to all other woods, but to prevent a too rapid consumption of yew, bowyers were ordered to make four wych-hazel, ash, or elm bows, to one of yew; and no person under 17 years of age, except those possessed of portable property worth 40 marks, or the sons of parents owning an estate of £10 per annum, was allowed to shoot with a yew bow, under penalty of 6s. 8d. for each offence. That distant counties might be properly supplied with bows and arrows, the king claimed and exercised the prerogative of sending, if necessary, all arrow-head, bow-string, and bow makers, not being freemen of the city of London, to any part of the realm that required the services of such artificers; and neglect of an order to visit a place after the receipt of instructions to repair thereto, was punishable by a fine of 40s. for every day the workman remained away.

In the reign of Henry IV. it was enacted that all arrow-heads should be well brased and hardened at the points with steel, and stamped with the name of the maker, under penalty of fine and imprisonment, and forfeiture of the arrows, &c., in default; and by another statute passed in the same reign, it was enacted that persons from places whence bow-staves were derived, should import four bow-staves for every ton of merchandise taken on board, under penalty of 6s. 8d. for every bow-stave deficient. In this reign the highest price permitted for a yew bow was 3s. 4d. In the reign of Edward IV. it was enacted that every Englishman, and every Irishman living with an Englishman, should have an English bow of his own height; and also that in every township shooting butts should be set up, at which the inhabitants were commanded to practise on holidays, under the penalty of one halfpenny for each neglect. In the same reign the king, in preparing for a war with France, directed all sheriffs to procure a supply of bows and arrows for the service of the state. In 1405, it was made penal to use bad materials in the manufacture of bows and arrows. In 1417 the archers of the army of Henry V. won the battle of Agincourt. This king directed the sheriffs of counties to take six wing-feathers from every goose for the feathering of arrows. In 1478 archery was encouraged in Ireland by statute. In the year 1424 James I. of Scotland, who was himself an excellent bowman, revived the practice of archery among his subjects. Richard III. lent 1000 archers to the duke of Bretagne. The same troops afterwards fought at the battle of Bosworth. In 1485 Henry VII. instituted the yeomen of the guard, who were then all archers, and in the 19th year of his reign the use of the cross-bow was forbidden by Act of Parliament, because the long bow had been of so much greater benefit to the nation. In this reign archery occupied an important position in the fashionable pastimes of the kingdom, and upon the occasion of the marriage of Henry with the Princess Elizabeth it formed a great feature among the nuptial festivities, the king himself joining in the shooting with heartiness and glee.

Several Acts were passed in the reign of Henry VIII. for the encouragement and promotion of archery; one ordered that butts should be erected and kept in repair in all townships, and that the inhabitants should practise shooting at them on holidays. The same Act directed that every able-bodied man, not being an ecclesiastic or a judge, should practise shooting with the long bow; and the guardians and employers of youth were ordered to bring up the boys in their charge to the practice of archery, neglect being punishable by fine. In this reign the practice of archery was strongly advocated from the pulpit by Bishop Latimer; and so jealous were the English of rival nations competing with them, that aliens were forbidden to use the long bow. The English victory at the battle of Flodden Field was due to the skill and courage of the archers. Edward VI. devoted much of his time to the practice of archery as an amusement, and his Journal, in which are many allusions to his successes and disappointments at matches, is still preserved in the British Museum.

Archery continued to be an object of attention and solicitude with the Legislature during the reign of Elizabeth, and the price of bows was again regulated by statute; also, bowyers were commanded to keep in hand always a sufficient stock of bows. Charles I. issued commissions to prevent the enclosure of fields near London, so "as to interrupt the necessary and profitable exercise of shooting with bows and arrows," and also for the restoration of all shooting-marks that had been already removed. And the earl of Essex, at the beginning of the civil war, raised a company of archers for the defence of the king. In the time of Charles II. archery was a highly fashionable and popular recreation with all classes of society, and the "Merrie Monarch" used frequently to take part with the ladies and gentlemen of his court in toxophilite meetings. Queen Catherine also showed deep interest in the fascinating pastime, and in the year 1676 she presented a silver badge to the "Marshal of the Fraternity of Archers." Both the king and queen frequently reviewed the numerous associations of archers then existent. In the spring of 1682 a grand fête was given by the London Artillery Company at the Artillery Grounds, at which there were present upwards of 1000 archers, and it is said that the gala outshone anything of its kind that had previously been seen in England; but from that time until the beginning of the present century, the attractions of archery appear to have been overlooked, and its practice neglected. In the *English Bowman*, a small book published in the year 1801, we find the following reason given as the cause of its revival in London :—

"About the year 1776, Mr Waring, who then lived with Sir Ashton Lever at Leicester House, and who may justly be styled the father of modern archery, having, by continual business, contracted an oppression upon his chest (arising principally from sitting too closely at his desk and pressing his breast too much against it, and which the most eminent in the faculty had in vain endeavoured to remove), resolved to try the effects of the bow in affording relief. He accordingly made it a regular exercise. and in a short time derived great benefit from the use of it, and ascribed his cure, which was perfect, to the practice of archery. Sir Ashton Lever, perceiving the good effects which so engaging an amusement had upon the constitution, followed Mr Waring's example, and took up the bow; he was soon joined by several of his friends who, in the year 1781, formed themselves into a society, under the title of the Toxophilites, and met regularly at Leicester House, having butts erected in the gardens belonging to it.

That society was the parent of the numerous societies of archers known about that period (*i.e.*, 1790). "The enthusiasm," says Hansard, in his *Book of Archery*, "can only be compared with that which animated the admirers of Shakspeare and the drama generally during the Garrick era."

There is now no means of ascertaining precisely the period at which the bow was relinquished entirely in these kingdoms as a weapon of war. Grose informs us that it was commonly used by the English soldiery for more than two centuries after the introduction of fire-arms, and indeed, long subsequently to the adoption of guns, the bow remained the favourite weapon of the army,—a fact which is not surprising when we learn, on the authority of Neade, a celebrated archer of Charles I., that the ordinary range of the bow was from 16 to 20 score yards, and that so rapid was the shooting of the archers, or so slow the firing of the musketeers, that an archer could shoot six arrows in the time occupied in charging and discharging one musket.

But although the bow has long been disused as a military weapon, it has ever been cherished in Great Britain, and particularly among the upper classes of society, as an instrument of delightful and healthful recreation; and it would be impossible to overrate the physical and moral advantages accruing from the regular practice of archery—one of the few "out-door" amusements that are as suitable for delicate ladies as for strong men. "There is," remarks Mr H. A. Ford, "no exercise more healthy or more rational, or which returns more true and genuine gratification to the man who practises it." As an exercise for ladies it brings all the muscles generally into healthy action, and is, in Mr Ford's opinion, admirably suited to meet the requirements of the fair sex,—"general and equal, without being violent—calling the faculties, both of mind and body, into gentle and healthy play, yet oppressing none—withal most elegant and graceful."

Another era in the annals of the art may be dated from the year 1844, when a national meeting of the archers of Great Britain and Ireland was held at York, since which time archery has assumed much importance as a national pastime, and year after year the wider competition which such assemblages have secured has brought forward bowmen and bowwomen, who, by their persistent efforts in carrying off honours, and that by the most remarkable achievements, have carried the art as nearly as possible to perfection. Under the auspices of the "Grand National Society" archery has been conducted through all the stages of actual revival and establishment as a favourite British pastime. Rapid progress has, in every respect, marked its modern career. It was only in the year 1845 that ladies began to compete publicly with men for the prizes offered at "The National," but at some of the matches, which have, without interruption, annually taken place since then, as many as 130 archeresses have participated in match-shooting, whilst at least an equal number of gentlemen have competed with them on some occasions, with a guaranteed prize list of about £400. These anniversaries have been held four times at Leamington and at Cheltenham; thrice at York and at Derby; twice at Shrewsbury, at Exeter, and at Bath; once at Edinburgh, Liverpool, Worcester, Oxford, the Alexandra Park (London), Clifton, Norwich, Birmingham, Hereford, Brighton, and Winchester. After the establishment of the Grand National meeting it was found necessary to fix an order of shooting; hence the origin of "The York round," on which all public competitions by archers are now conducted, and which, for gentlemen, consists of 6 dozen arrows at 100 yards, 4 dozen at 80 yards, and 2 dozen at 60 yards; and for ladies, 4 dozen arrows at 60 yards, and 2 dozen at 50 yards. By this arrangement archers living in various parts of the three kingdoms can ascertain their relative proficiency. It is upon two days' shooting, or the result of a "double round," that the Grand National prizes are awarded on "value" alone, as the best criterion of good and central shooting. The principal of these prizes are the champion's gold medal for gentlemen, and the challenge silver bracer and brooch for ladies. These much coveted honours are awarded by a majority of points only; and the points for the champion's medal are reckoned as follows:—Two for the gross score, two for the gross hits, one for best score at 100 yards, and one for the best hits at ditto, and the same at 80 and 60 yards—making ten points in all. The ladies' challenge bracer (presented by the West Norfolk Bowmen) is awarded on the same principle, namely, for the greatest number of points—eight in all. The highest score ever made by a champion was 1251, with 245 hits, at Cheltenham in 1857, by Mr Horace A. Ford, the author of *The Theory and Practice of Archery*, who won the medal of Great Britain as many as eleven times, and is, without doubt, the finest shot England has seen since the days to which legends and distance lend a somewhat doubtful glory, his scores being absolutely without parallel. He has now retired from public life as an archer. The nearest approach to any of his victories has been made by Major Hawkins Fisher, who carried off the medal in 1871 with 955, and has been champion in the years 1871-72-73-74. Mr Peter Muir, the greatest archer, probably, that Scotland has produced, at any rate in modern days, was the champion in 1863, scoring 845. Mrs Horniblow became the possessor of the lady champion's bracer no less than ten times, and the highest score she ever made in obtaining it was 764, at Leamington, in the year 1873. To this lady is due the honour of having signally demonstrated that the bow really was a weapon adapted to woman's use, and capable of evidencing, in their hands, not the perfection of grace only, but that of skill and talent also. To the Grand National Society, in the first instance, is this great increase of skill mainly owing, but beyond this, increased skill has led to increased taste and liking for the amusement, till, in an ever widening circle, nearly every county of England has become included within it. This has led to the establishment of other great meetings, till, at the time the present article is written, besides numberless meetings of private clubs, there are several public matches open to all, where formerly there were none. Thus we have the Grand National itself, the Leamington and Crystal Palace meetings, the Grand Western (where two handsome challenge prizes reward the shooting both of the champion and championess of the west of England), and a Scotch national meeting, where a champion gold medal, presented by Mr T. Macfarlane of New Zealand, and exclusively confined to Scotland, is annually shot for, being awarded to the successful bowman, according to the rules for the champion medal of Great Britain.

There are several societies of archers in the three kingdoms, but the most noted of the kind now existing are the following:—

The Royal Company of Archers.

The king's body guard for Scotland was first constituted in its present form in the year 1676, by an Act of the privy council of Scotland. An earlier origin has been claimed for the company, it being said by some that it was originally formed by the commissioners for enforcing the exercise of archery appointed by James I. of Scotland, who picked out the most expert bowmen in the various counties, and constituted them into a body of guards to defend the king's person, in which distinguished station they displayed great devotion and bravery at the battle of Flodden, the body of the king being afterwards found surrounded by those of his attached archers' guard. This, however, is mere tradition, no authentic record of their existence being found until the above-mentioned year 1676, when the minutes of the Royal Company begin by stating, that owing to "the noble and usefull recreation of archery being for many years much neglected, several noblemen and gentlemen did associate themselves in a company for encouragement thereof . . . . . and did apply to the privy council for their approbation, and after several meetings, did adjust and concert several articles and regulations of the said company, and did further apply to the privy council for their approbation, which was granted." The minutes of the company have been kept with great regularity from that time down to the present, with the exception of a period of about twenty years at the end of the 17th century, during which time there are no records. It is not supposed that the company was extinct at that time from what can be gathered from the succeeding minutes. It is probable, however, that during the Revolution the Royal Company was principally composed of upholders of the house of Stuart, and that on this account their existence was for a time suspended. This may be true, as we find that the company was subsequently a strong Jacobite body, but whether it is the case or not, it is certain that the records recommence in 1703 by informing us of the election of a captain-general to succeed John, second earl of Argyle, who held that office from the formation of the company in 1676, and who had just died. The new captain-general was Sir George Mackenzie, Viscount Tarbat, afterwards created earl of Cromarty. Owing to his exertions while principal secretary of state for Scotland in 1703, he procured for the company a new charter from Queen Anne, renewing all their former rights and privileges, and conferring others, all which were to be held of the Crown for the *reddendo* of a pair of barbed arrows. This *reddendo* was paid to George IV. at Holyrood, when he visited Scotland in 1822, and to the present sovereign, Queen Victoria, on a similar occasion in 1842.

The history of the Royal Company since 1703 has been one of great prosperity. Large parades were frequently held, and were attended by numbers of archers dressed in the uniform of the body, which, in the last century, consisted of a green tartan coat and white knee-breeches. On such occasions the whole population of Edinburgh and the surrounding districts turned out to view the procession, as the company, with music and colours, marched down the Canongate to Leith Links, there to shoot for a prize. Many distinguished men marched in their ranks, and, both at their competitions and at the mess table, the utmost hilarity and good fellowship prevailed. Several of the leading insurgents in 1745 were members, but the company was not at that time suspended in any way, and a few years later no subjects more loyal or more attached to the constitution could be found in Great Britain.

In 1777 the Royal Company erected a large and handsome hall in the vicinity of their shooting-ground in the Meadows, Edinburgh. They meet there periodically for the transaction of business and to dine. The hall is decorated with several very fine portraits of eminent members of the body, in various uniforms, according to the rank which they held in the company and the time in which they lived. Among them are some masterpieces of Raeburn, Watson, Gordon, Grant, P.R.A., Macnee, &c.

In 1822, when king George IV. visited Scotland, it was thought appropriate that the Royal Company should act as his Majesty's body guard during his stay. Consisting as the company did, and still does, of representatives of almost all the noble families of Scotland, together with a large proportion of landed gentry, professional men, and others, it was considered that no fitter body could be chosen, especially as there was a tradition, as we have seen, that the Royal Company had at a former period acted in a similar capacity. On the landing of the king he was received by a detachment of the body, who surrounded his carriage inside the cavalry escort and marched up with it to Holyrood. They occupied the same position in subsequent state processions; while at the levee and drawing-room held by his Majesty they lined the staircase and presence chamber, performing the duties usually assigned to the band of gentlemen-at-arms. When Queen Victoria visited the Scottish capital in 1842, the Royal Company again did duty, and the last time they were called out in their capacity of royal body guard was in 1860, on the occasion of the great volunteer review in the Queen's Park, Edinburgh.

King George IV., besides authorising the company to take, in addition to their former name, that of "The King's Body Guard for Scotland," presented to the captain-general a gold stick, thus constituting the company part of the royal household. In virtue of this stick the captain-general of the Royal Company takes his place at a coronation or similar pageant immediately behind the gold stick of England, who, with the exception of the officers on guard for the day, is next the sovereign's own person. The lieutenants-general of the company have silver sticks; and the council, which is the executive body of the company, possess seven ebony ones. George IV., in addition to the grant of a gold stick, appointed a full dress uniform to be worn by members of the company at court, when not on duty as guards, in which latter case the ordinary field dress is used. The court dress was scarlet and gold, but was changed in 1831 to a green coat with green velvet facings richly embroidered with gold thistles and arrows, gold epaulettes, crimson silk sash, gold-laced trousers, and cocked hat with green plume. The officers wear a gold sash in place of a crimson one, and an *aiguillette* on the left shoulder. All ranks wear swords. The shooting uniform has been frequently changed. We are not told what colour the coat was at the formation of the company, but there was a distinctive dress introduced about that time. In 1715 a green tartan was adopted (now the 42d tartan), which continued, with several modifications and alterations, to be the uniform down to 1829, when it was changed to green cloth. The present field dress consists of a dark green tunic with black braid facings, with a narrow stripe of crimson velvet in the centre; shoulder wings and gauntleted cuffs similarly trimmed; dark green trousers with black and crimson stripe; a bow case worn as a sash, of the same colour as the coat, with a centre ornament of two arrows crossed saltierwise in a garter tie, surmounted by a crown; a black leather waist-belt, with richly chased gold clasp; a short sword, gilt hilted, made after the fashion of a Roman gladius, Balmoral bonnet, with thistle ornament and eagle's feather. The mess uniform consists of a dark green dress coat with velvet collar and gilt buttons, with a crown on them, white waistcoat, and black trousers.

The Royal Company possess two sets of colours. The first banner was got in 1714, and bears a representation of the common seal of the company, viz., a yew tree *proper*, supported dexter and sinister by an archer with a bow in one hand and an arrow in the other. The second was procured in 1732, and bears on one side a lion rampant *gules*, on a field *or*, with the motto "*pro patria dulce periculum*," and on the other a St Andrew, with a large thistle above his head, with the motto, "*Nemo me impune lacessit.*" King William IV. presented the company with a new stand of colours in 1832. The one banner combines the old ones, and the other has the Royal Scottish arms, with the words "King's Body Guard for Scotland."

The following are the noblemen who have held the office of captain-general since 1676:—

1676–1703, John, second earl of Atholl.
1703–1714, Sir George Mackenzie, first earl of Cromarty
1715–1720, David, third earl of Wemyss.
1724–1743, James, fifth duke of Hamilton and Brandon.
1743–1756, James, fourth earl of Wemyss.
1756–1778, Charles, third duke of Queensberry.
1778–1812, Henry, third duke of Buccleuch.
1812–1819, Charles, fourth duke of Buccleuch.
1819–1823, John, fourth earl of Hopetoun.
1824–1830, James, third duke of Montrose.
1830–1838, George, ninth earl of Dalhousie.
1838– The present duke of Buccleuch.

Most of the prizes shot for by the Royal Company are held for a year by the winner, and in some cases he receives a grant of money to enable him to affix a silver or gold medal with his name and crest inscribed thereon to the prize. The only prize which becomes the winner's absolute property is one of £20, presented annually by her Majesty to be expended in the purchase of a piece of plate. This prize was first given by the Scottish privy council at the very beginning of the company. It was not, however, continued for many years, but was revived by his Majesty George III. in 1788, and has since been shot for regularly. The following is a list of the principal prizes shot for by the company:—

1. Musselburgh Silver Arrow, given by the magistrates of that town, and first shot for so far back as 1603. Now the competition is confined to members of the Royal Company, but at that time it was probably open to all comers. 2. Peebles Silver Arrow, shot for at that town. This arrow bears medals extending back to 1626, but it was not shot for by the Royal Company until 1786. 3. Silver Arrow presented to the company by the magistrates of Edinburgh in 1709, and shot for from that time. 4. Selkirk Silver Arrow, first shot for by the company in 1818, but in itself a very ancient prize. 5. Silver Punch Bowl and Ladle, subscribed for by members in 1720, and having the gold medal of the winner of each year attached. 6. Dalhousie Sword, a richly ornamented Indian sword, presented by captain-general the earl of Dalhousie, in 1833. 7. The Hopetoun Royal Commemoration Prize, a handsome silver vase and gold medal, presented by captain-general the earl of Hopetoun, to commemorate George IV.'s visit to Scotland in 1822. 8. Spens Anniversary Medal, shot for in honour of the memory of Dr Nathaniel Spens, an old and favourite member in the end of last century. 9. Prize given by the town of Biggar 10. Silver Arrow, presented by the magistrates of Montrose. All these prizes are shot for in the field at a distance of 180 yards. There is, however,—11. St Andrew's Cross, presented in 1801 by Sir George Mackenzie of Coul, Bart.; shot for at 200 yards. There are two prizes shot for at 100 yards, namely, 12. A Gold Medal made out of "pagodas," being part of the money paid by Tippoo Sultan at the treaty of Seringapatam, presented by Major James Spens in 1793; and 13. A Silver Bugle Horn, presented in its present shape in 1830, by Sir Henry Jardine, Knt., but shot for for some time previously in a less handsome form. There are three prizes shot for at butts, at a circular piece of card-board four inches in diameter, at a distance of 100 feet. The most ancient of these is—14. The Goose Medal, or the Goose. The old mode of competing for this was by building a live goose in a turf butt, the head only being exposed to view, and he who hit the head and killed the goose was entitled to have her Of course, this barbarous practice has been long discontinued, though it remained till after the middle of last century. In place of the goose's head, a small glass globe is put into the centre of the card-board mark on the butt, and he who breaks the globe with his arrow receives a gold medal, to be worn for the ensuing year. 15. Papingo or Popinjay Medal, presented in 1831, and originally competed for by shooting at a stuffed bird, a parrot or popinjay, fixed to the top of a high pole. He who brought the bird down was adjudged victor. It having been found inconvenient to shoot for the prize in this manner, it is now competed for in the ordinary fashion at butts. 16. A Gold Medal, held for a year by the person making the greatest aggregate score on three appointed days.

The affairs of the company are managed by a council of seven, who are elected by the whole company annually. Although the company has a right, as a body, to elect their own officers and admit new members, yet both those powers have for many years been left in the hands of the council. The fees of entry to the Royal Company are £25, and the entrant has also to be balloted for by the council. There are several "uniform" dinners held in the course of the year, which are very popular both with members and their friends. Smaller and less pretentious, though not less pleasant, are the "match" dinners held once a month by the shooting members, after a friendly match shot at rovers or butts. The average number of members belonging to the Royal Company is between 500 and 600.

The Royal Toxophilite Society is now established at the Archers' Hall, Inner Circle, Regent's Park, London, where it has a handsome building for the use of its members, and ample shooting ground. It was founded in 1781 by Sir Ashton Lever, and represents the two ancient bodies, "The Finsbury Archers" and "The Archers' Company of the Honourable Artillery Company," and possesses, among other plate, the large silver shield given to the Archers' Company by Queen Catherine of Braganza (consort of Charles II.), and also silver arrows of the same and of earlier periods. The Royal Toxophilite Society have occupied their present ground (about six acres in extent) since 1832, when they obtained possession of it from the Woods and Forests, and erected on it their "Archers' Hall." The entire cost of the building, laying out the grounds, furnishing, and finishing, amounted to £4548, 9s. 6d. The society has for many years enjoyed special royal patronage. King George IV., who was fond of archery, shot, when Prince of Wales, with the members in their gardens at Leicester House, and on his becoming patron of the society in 1787, it assumed the title of "Royal," by which it has ever since been distinguished. King William IV. was also its patron, as was the late Prince Consort. The Prince of Wales is at the present time the patron of the society, of which the earl of Dudley is the president.

The Woodmen of Arden hold their meetings at Meriden, in Warwickshire. The society was revived, after a long interval, in the year 1785. The number of members is limited to 80; but the standing rules relating to the election of a member were, by general consent, suspended in the case of the late Sir Robert Peel. This occurred at the jubilee festival in 1835. The earl of Aylesford is lord warden of the society, whose shooting grounds, which are in the forest of Arden, consist of about 12 acres of land. A forest hall was erected in 1844. The Woodmen, exercising a nominal, as their predecessors did a real authority, over vert and venison, give appropriate designations to their officers. Of these, the lord warden is chief; and they have likewise master foresters and verderers. At the grand target, or annual wardmote, whoever hits the gold first is styled (for the year ensuing) Master Forester; and whoever gains the second gold becomes the Senior Verderer for the same period. In 1787 the silver bugle horn of Arden was presented to the society by the earl of Aylesford; it is never shot for at a less distance than nine score yards, which may be extended to twelve score. In 1788 the countess of Aylesford presented to the society the "silver arrow," to be annually shot for at nine score yards. Gold and silver medals are also presented to the master forester and senior verderer; and there are the Digbean gold medal, *optime merenti*, the possessor of which ranks as Captain of Numbers, he having gained the greatest number of prizes at the grand target; and the Digbean silver medal, *bene merenti*, which confers the Lieutenancy of Numbers upon the member who gains the next greatest number of prizes. The winners of these medals, which are shot for at 100 yards, take rank, for the year thereafter, next to the senior verderer.

Practical Archery.

Implements for the practice of archery are principally made in London and Edinburgh, and are of various degrees of excellence. It cannot be too strongly impressed upon archers that they should select their gear from a maker of undoubted "good report." In the choice of a bow preference should be given to one which is under, rather than over, the strength which an archer can use without difficulty. The power required to draw an ordinary bow, for a gentleman, ranges from 40 to 60 ℔ (*i.e.*, power to draw the arrow to the point)—46 to 50 ℔ being the average power used for the "York Round." The "Royal Archers" at Edinburgh and the "Woodmen of Arden" are the only clubs shooting longer distances than are recognised by "the York." These longer distances are 180, 200, and 220 yards, requiring bows of from 56 to 64 ℔ power. Gentlemen's bows are 5 ft. 10 in. and 6 feet long. Ladies' bows, of course, are lighter, and can be drawn by a power of from 24 to 32 ℔, the length being from 5 ft. 3 in. to 5 ft. 6 in. Bows are made of various kinds of wood, such as lancewood, snakewood, washaba, and yew,—the last being generally preferred for sweetness of material and steadiness of cast, though lance and other woods are found to be more durable, much cheaper, and quite as well adapted for practice. Bows are made of three pieces, two pieces, and one piece, and are called three-woods, two-woods, and self. Self bows usually follow the string. Two-wood and three-wood bows being made a little reflex, should retain their shape. It is important that all bows should be preserved from damp, especially those constructed of two or three pieces, as, not only does moisture affect the wood and cause it to warp, but it also dissolves the glue by which the parts are united, and renders the implement useless. For correct and precise shooting an archer must possess himself of the best arrows he can procure. These should be of a weight adapted to the power of the particular bow for which they are intended, and must be alike in thickness, shape, and stiffness. The standard length of an arrow used by gentlemen is 28 inches, and its weight is equal, in standard silver coin, to from 4s. to 5s.; those weighing from 4s. 6d. to 4s. 9d. being used with bows of from 46 ℔ to 50 ℔. The lady's arrow is 25 inches long, and weighs, in silver coin, from 3s. to 3s. 6d. Arrows are manufactured generally of red-pine timber, and the best are footed with a piece of hard wood—usually bullet-tree—glued on one end, upon the point of which the iron pile is fixed, and into the other end is inserted a wedge-shaped piece of horn, called the nock, in which a notch is made for the reception of the bow-string when the archer is shooting. The feathering of arrows depends in some measure upon the taste of the shooter. An arrow has three feathers—now generally taken from a turkey's wing—affixed edgewise at the nock end, about an inch from the end, equi-distant from each other, and parallel to the flight. The wings are much shorter than they were formerly, ranging from $1\frac{3}{4}$ to $2\frac{1}{2}$ inches in length, as the shooter may desire. One feather on each arrow is of a different colour from the rest, and is placed perpendicularly to the line of the nock; it is called the guide-feather (or "cock-feather"), as it enables the archer more readily to place the arrow on the bow-string. By using feathers of the right or left wing for the same set of arrows, the natural curve of the feather is sufficient to impart to the arrow in its passage through the air a rotatory motion equivalent to the flight of a rifle ball. The best shaped arrow is nearly the same thickness from the pile to the under end of the feathers, from which it tapers off slightly to the nock. The full-shouldered, or nearly parallel-shaped pile, is to be preferred.

In addition to his bow and arrows an archer, to be fully equipped, must have a drawing-glove to protect the fingers of the right hand; an arm-guard made of stout calf, morocco, or other leather, to shield the left arm from the stroke of the string after the discharge of an arrow; a waist-belt in which to carry the arrows when shooting, and to which are attached a green worsted tassel for the removal of dirt, &c., from the points of discharged arrows; and an ivory grease-pot, containing grease for the drawing fingers of the glove, of which there are various kinds, every archer using that which suits him best. A doeskin glove, with the first three fingers tipped with smooth, firm calf or pig skin, about $1\frac{1}{4}$ inch long, upon the fingers, and having a strap to buckle round the wrist, is about the easiest and best for use. The flat tab covering the three fingers allows them perfect freedom; but the ordinary draw-glove, with cylindrical points and straps up the back of the hand and around the wrist is perferred by many archers, whilst others again prefer screw tips, fitting each finger separately, and with a strap on the front. Then there is the quiver, which is generally made of Japanned tin. It is used to preserve the arrows from damp, &c., also for keeping the reserve arrows in, as only three are used when shooting in company; it is never worn except when roving.

Targets consist of straw basses with painted canvas faces sewed on them. The "National" targets are 4 feet in diameter, and they have on their faces five circles or divisions, the centre one being gold, and scoring 9; the red scores 7; blue, 5; black, 3; and the white or outer circle, 1. These targets are placed on stands constructed of three ribs of iron jointed at the top; the two side ribs have spikes on the front edge on which the targets rest: the centre rib is thrown behind, as a spur to support the triangle. There should always be a pair of targets provided by an archer in practising, in order to save time and trouble; and a young archer has always been advised to practise at a short distance, and to lengthen it as he progresses—commencing at 20 yards, till he is able to hit the smallest mark, which will prove that he has attained command over his bow.

To enable an archer to keep a record of his shooting the following scoring-card will be found useful (the marks may be made with the point of a pin or pencil):—

Shooters.	Gold.	Red.	Blue.	Black.	White.	Hits.	Value.
A.	... .	....	....	....	....	41	167
B.	....	...	...	.....	.....	19	79
C.							

There is no "royal road" to archery, and more real progress towards proficiency in the bow may be gained in a few hours under the practical guidance of an adept in the art, than can possibly be imparted by all the treatises upon the subject that ever were written; yet, for those who would master the rudiments of the science, a few words may be useful upon what have ever been considered the "five points of archery," which Ascham in his celebrated work describes as "standing, nocking, drawing, holding, and loosing."

1. Roberts, in his *English Bowman*, remarks upon the difficulty of conveying by verbal description so accurate a representation as the pencil can give of an archer drawing his bow. It is a model of gracefulness, the attainment of which is so pointedly recommended by Ascham. Mr Ford in his disquisition, says the "heels

should be about six or eight inches apart. . . . . . The feet must be flat and firm on the ground, both equally inclining outwards from the heels, ... the position of the feet being such that a straight line drawn from it would intersect both heels. . . . . The knees must be perfectly straight, not bent in the slightest degree. . . . . The weight of the body should be thrown equally on both legs. . . . In short, the footing must be firm, yet at the same time easy and springy, and the more natural it is the more likely it is to possess these qualities." The accompanying woodcut will best illustrate the attitude which an archer should assume.

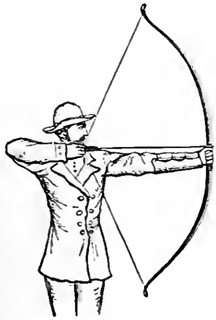

Fig. 1.

2. To string a bow, take it by the handle in the left hand, with the flat side (or back) towards the wrist; place the horn of the under end in the hollow of the left foot; then put the palm of the right hand on the back of the upper end of the bow, below the loop of the string, with the thumb on the one side, and the forefinger *bent* on the other side of the bow, and with the left hand fixed as the fulcrum. Then with the right hand press the string upwards until it reaches the notch in the horn, and the bow is strung, and should exhibit a space of about 5½ inches between the string and the interior of the handle.

"Honora Spencer (Mrs Sharpe), who wrote specially upon archery from a lady's point of view, in alluding to the stringing of the bow, remarks:—'Whilst the right wrist is pressing the bow downwards the other hand should be pulling your bow towards you, each hand with equal pressure, each hand with equal strength. At the same moment that you press and pull, you must use your first two fingers (of course of the right hand) in slipping the string into the groove intended for its reception.' Another mode is recommended, and we are told 'to press the thumb and forefinger closely against the sides of the bow, whilst you pull smartly at the handle.' This, I believe, is the accepted method among gentlemen; but a lady has not often sufficient power in her thumb and forefinger to bend the bow and string it at the same moment; besides this, the pressing of the bow with the wrist is far more graceful for a lady. The same remark and advice apply to the unstringing of the bow, only that the string has to be slipped *out* of the groove. If you find, after some half-dozen attempts that this method of stringing strains neither the right nor left wrist, you may safely conclude that your bow is suited to your strength."

Fig. 2.

3. The bow being now ready to receive the arrow, the archer must "nock," or place it on the string at a spot prepared for it (which should be about ⅜ths of an inch above the upper end of the handle) with the guide feather furthest from the bow, catching the string with two or three fingers, and the arrow between the first and second.

4. He must then take a firm position with his left shoulder towards the target, turning his head only from his neck, and looking over his left shoulder. He must then raise the bow with his left hand, keeping the upper end inclined one or two degrees from his body, and with his right hand draw the arrow to the level of his chin, and below his ear, to which point the arrow should always be drawn while the left hand and arm should be elevated or depressed, according to the distance to be shot, or the strength of the bow.

5. When the arrow is fully drawn, dwell for a moment or two to steady the aim; then "quit" or discharge the arrow, by allowing the string to pass smoothly over the finger points without jerking. The position which a lady should assume whilst in the act of discharging her arrow is illustrated by the annexed figure, the correctness of which might have been increased by the elbow of the left arm, in which there should not be the slightest bend, being held straighter.

Fig. 3.

Except for line there is no accepted theory of taking aim. Due regard must be paid to the weather. When it is calm, the archer must fix the position of the target in his vision, and experience will soon tell him how to find the line and degrees of elevation. In wind, the line and degrees must be varied to suit the conditions of the atmosphere; in a cross wind there must be an adaptation to the direction of the wind; whilst in an up and down wind more or less elevation must be taken according to the strength of the current.

The following is a summary of points well worthy of being remembered by every shooter:—Have the string straight on your bow. *Always* nock on the same place. Place the arrow *over* the string, not between it or the bow. Do not have the arrow too tight on the string. Draw slowly and evenly. Turn your elbow a little upwards. Slant the bow a little to the right. Always draw the arrow the same length. Draw a little below the right side of the chin. Always, while drawing, keep the elbow of your right arm level with the shoulder. Keep the "point of aim" always *directly* in view. Look along the *whole length* of the arrow. Be carefnl to point it perfectly straight. Do not shut the left eye; yet do not aim with it. Make the *left* arm always that by which you change the elevation. Do not hold the bow long *fully* drawn. Never let the fingers of your right hand follow the string. Do not jerk, but loose smoothly. Be certain that your bow-arm does not move when loosing.

"Flight" and "clout" shooting has ceased, and "roving" is now practised only in Britain by the two clubs previously mentioned. They use a target 3 feet in diamater, and count arrows four bow lengths from the target; the nearest arrow counts two. Shooting at butts is still practised, the butts being from 80 to 100 feet apart; the mark is a round piece of pasteboard 4 inches in diameter. The shooting is nearly point blank. (J. SH.)

A Glossary, or Explanation of Terms, &c., made use of in Archery.

ALLOW, ALLOWANCE.—An archer is said to *allow*, or make allowance for the wind, when he shoots somewhat wide of the mark, and on that side of the mark nearest the wind, in order that the wind may bring his arrow into the line of the mark.
ARROW, BEARING.—An arrow which possesses a steady flight.
ARROW, BOB-TAILED.—An arrow increasing in bulk, in a regular proportion, from the nock to the pile.
ASCHAM.—A sort of cupboard, or case, to contain bows, and sometimes arrows, and other implements of archery.

B.

BACK OF A BOW.—The exterior, or flat side.
BELLY OF A BOW.—The interior, or rounded side of a bow
BOW-ARM.—The arm employed in holding the bow.
BOW, SELF.—A bow made of one entire piece of wood.
BOW-SHOT.—The distance which an arrow flies from the bow.
BOWYER.—A maker of bows.
BUTT.—A mound of earth, upon which a mark to shoot at is placed.

C.

CAST, TO.—To become warped.
CAST, THE.—The right of shooting the first, by winning at the last shot, which is called getting the cast.
CHRYSAL, or CRYSAL.—A kind of pinch or crack in a bow.
CLOUT.—A small white target, placed near the ground.
CLOUT-SHOOTING.—Shooting at clouts.
COCK-FEATHER.—That feather on the arrow which is uppermost, and of the darkest colour.
COMPASS, TO KEEP.—To observe a due elevation.
CUT THE MARK, TO.—An arrow is said to cut the mark, when it flies straight towards it, but falls under it.

D.

DRAWING THROUGH THE BOW.—This signifies drawing so far that the point of the arrow comes within the belly of the bow.

E.

ELEVATION.—The act of raising the bow in shooting at the mark.
END.—The place where a mark is fixed.
EYE OF THE STRING.—That part of it which occupies the upper horn of the bow.

F.

FAST.—A word used to caution persons from passing between the shooter and the mark, and to direct them to stand still.
FLETCHER.—An arrow-maker.
FLIGHT.—The distance or path in which an arrow flies.
FOLLOW THE STRING.—A bow is said to follow the string, when, by its use, it has lost its original straightness, and has obtained a curve or inclination forward.

G.

GONE.—An arrow is said to be gone, when it may from its flight be judged to fall wide of, or far from, the mark.
GRAFTED BOW.—One made of two pieces of wood joined at the handle.

H.

HE! HE!—This exclamation is said to have been an archer's word of call, handed down from very ancient days.
HIT.—A stroke in the target or mark.
HOME.—An arrow is said to be drawn home when it is drawn as far as it ought to be.
HORNS OF THE BOW —The ends of the bow, which are tipped with horn.

I.

INCHES.—A distance allowed round the butt-mark, within which an arrow must fall to count.

K.

KEEPING A LENGTH.—Shooting the exact distance, although not straight.

L.

LENGTH.—The distance to be shot.
LIMBS.—The part of the bow above and below the handle.

M.

MARK.—Any object shot at.

N.

NOCK.—An ancient word still used by archers for notch; nocks, therefore, are the notches in the horns of bows and arrows.
NOCKING POINT.—That part of the string on which the arrow is placed.
NOOSE.—The end of the string which occupies the lower horn.

O.

OVER-BOWED.—An archer is said to be over-bowed when the power of his bow is above his command.
OVER-HAND.—Shooting over-hand is to shoot at the mark over the bow-hand.

P.

PAIR OF ARROWS.—In archery three arrows are termed a pair, on account of the liability of one to break.
PETTICOAT, OR SPOON.—The ground of the target beyond the white.
PILE.—The head of an arrow, usually made of steel or iron.
POPINJAY.—A wooden bird, used as a mark, particularly in Scotland.

Q.

QUIVER.—A case in which arrows are kept or deposited, generally made of tin.

R.

ROVING.—Shooters at rovers, which are casual marks, of uncertain distance.

S.

SELF-BOW.—One made of a single piece of wood, or grafted.
SHAFT.—An arrow, so called when it wants only the head.
SHAFTMENT.—That part of the arrow occupied by the feathers.
SHOOT, A.—An arrow shot.
SINKING A BOW.—Reducing its force or stiffness.
SNAKE.—An arrow is said to snake when it works itself under the grass.
STANDING BOW.—A bow that stands well without sinking.
STELE.—An arrow without feather or head.

T.

TAB.—A piece of flat leather, used instead of the fingers of the shooting glove.
TARGET.—A mark to shoot at, consisting of divers coloured circles.
TARGET-CARD.—A card coloured in the same manner as the target, containing the names of the shooters, and used for scoring their respective hits.

U.

UNDER-BOWED.—Using a bow that is too weak to shoot well with

W.

WEIGHT OF A BOW.—The weight or power which a bow requires to draw it properly up.
WHIPPING, THE.—The material used to enwrap the nocking point.
WIDE ARROW.—One that falls wide of the mark
WIND, DOWN.—When the wind blows directly from the shooter down to the mark.
WIND, SIDE.—When it blows directly across the line of mark.
WIND, UP.—When it blows directly from the mark to the shooter

ARCHES, COURT OF THE. This court derives its name from its ancient place of judicature, which was in the church of St Mary of the Arches (*de Arcubus*), the modern representative of which is now called ordinarily Bow Church. The modern church is on the south side of Cheapside, in the city of London, and stands on the site of a very ancient church, which was burnt down in the great fire of London in 1666, and which had a very fine arched crypt, whence it derived its name. The ecclesiastical tribunal, which has passed for a long time by the name of the Arches Court, is the court of appeal of the archbishop of Canterbury, as metropolitan of the province of Canterbury, and the proper designation of the judge is the Official Principal of the Arches Courts, but by custom he has come to be styled the Dean of the Arches, from the circumstance that the office of dean has been in modern times usually united in the same person with that of the official principal of the court of appeal. The office of the dean of the Arches may now be regarded as extinct, or at least as purely titular, like that of the dean of Bocking in Essex, inasmuch as the peculiar jurisdiction which he exercised as dean (*decanus*) over thirteen churches, locally situated within the diocese of London, but exempt from the bishop's jurisdiction, has been abolished, and the churches have been placed by statute under the ordinary jurisdiction of the bishop of London. It was, no doubt, owing to the circumstance that the Arches church was exempt from the bishop of London's jurisdiction that it was selected originally as the place of judicature for the archbishop's court. After the College of Advocates was incorporated and had established itself in Doctors' Commons, the archbishop's court of appeal, as well as his prerogative court, were usually held in the hall of the College of Advocates, but since the destruction of the buildings of the college, the court of appeal has had no settled place of judicature, and the official principal appoints from time to time its sittings, which have been held for the most part in Westminster Hall. The appeals from the decisions of the Court of Arches were formerly made to the king in Chancery, but they are now by statute addressed to the king in Council, and they are heard before the Judicial Committee of the Privy Council. By 23 Henry VIII. c. 9, the Arches Court is empowered to hear, in the first instance, such suits as are sent up to it by letters of request from the consistorial courts of the bishops of the province of Canterbury; and by the statute 3 and 4 Vict. c. 86 (the Church Discipline Act) this jurisdiction is continued to it, and it is further empowered to accept letters of request from the bishops of the province of Canterbury after they have issued commissions of inquiry under that statute, and the commissioners have made their report. The official principal of the Arches Court is the only ecclesiastical judge who is empowered to pass a sentence of deprivation against a clerk in holy orders. (T. T.)

ARCHIDONA, a town in the province of Malaga, in Spain, situated on the slope of a hill, about 10 miles W.N.W. of Loja. It seems to have been a flourishing place under the Romans, to judge by the statues, columns, and other remains which are found, but it is now, in the words of O'Shea, a "wretched village with nothing to visit." The inhabitants, about 7600 in number, are employed in fruit-growing, weaving, oil-pressing, and bacon-curing.

ARCHIL, or ORCHIL (*Orseille*, Fr.), a purple dye yielded by various species of lichens. The name is supposed to originate from the Portuguese *rocha*, a rock, in allusion to the source from which the raw material is derived. Archil can be extracted from many species of the genera *Roccella*, *Lecanora*, *Umbilicaria*, *Parmelia*, and others, but in practice two species of *Roccella*,—*R. tinctoria* and *R. fuciformis*, are almost exclusively used. These, under the name of "Orchella Weed," are imported from the Portuguese colony of Angola, on the west coast of Africa, where the most valuable kinds are gathered; from Cape de Verde Islands; from Lima, on the west coast of South America; and from the Malabar coast of India. They grow on maritime rocks and on trees along sea-coasts, and it will be seen that the species are very widely distributed. The colouring properties of the lichens do not exist in them ready formed, but are developed by the treatment they receive at the hands of manufacturers. Small proportions of a colourless, crystalline principle, termed orcine, is found in some, and in all a series of acid substances, which on treatment split up into orcine and other products. Orcine in presence of oxygen and ammonia takes up nitrogen and becomes changed into orceine, which is essentially the basis of all lichen dyes. Archil is prepared for the dyer's use in the form of a "liquor" and a "paste," and the latter when dried and finely powdered forms the "cudbear" of commerce, a dye formerly manufactured in Scotland from a native lichen, *Lecanora tartarea*. The manufacturing process consists in washing the weeds, which are then ground up with water to a thick paste. If archil paste is to be made this paste is mixed with a strong ammoniacal solution, and agitated in an iron cylinder heated by steam to about 140° Fahr. till the desired shade is developed—a process which occupies several days. In the preparation of archil liquor the principles which yield the dye are separated from the ligneous tissue of the lichens, agitated with a hot ammoniacal solution, and exposed to the action of air. When carbonate of potassium or sodium is added, a blue dye known as litmus, much used in chemical testing, is produced. French purple or lime lake is a lichen dye prepared by a modification of the archil process, and is a more brilliant and durable colour, than the other. The dyeing of worsted and home-spun cloth with lichen dyes was formerly a very common domestic employment in Scotland; and to this day, in some of the outer islands, worsted continues to be dyed with "crottle," the name given to the lichens employed. Stale urine is the form of ammoniacal liquor used in these localities, and that in early days was the recognised source of ammonia in the manufacture.

ARCHILOCHUS, one of the first Greek lyric poets, was born at Paros, one of the Cyclades. The date of his birth is uncertain, but he flourished between 720 and 680 B.C. His father, Telesicles, was of noble family, and had been selected to consult the Delphic oracle relative to sending out a colony from Paros. His mother, Enipo, was a slave. While still young, Archilochus gained a prize for a hymn to Demeter; he soon after left Paros and proceeded to Thasos, according to some authorities, as leader of a colony. But his chief reasons for leaving his native place seem to have been personal disappointment and disgust. Lycambes had promised him his daughter Neobule in marriage, and had afterwards withdrawn his consent. Archilochus, taking advantage of the licence allowed at the feasts of Ceres, poured out his wounded feelings in verses of unmerciful satire. Lycambes he accused of perjury, and his daughters of leading the most abandoned lives. Such was the effect produced by his verses, that Lycambes and his daughters are said to have hanged themselves. The satire was written in iambics, a measure introduced for the first time, and from its structure admirably adapted for light sarcastic poetry. At Thasos the poet passed some unhappy years, and incurred the great dishonour of throwing away his shield and fleeing from the field of battle. He does not seem to have felt the disgrace very keenly, for, like Alcæus and Horace, he commemorates the event in his verses. After leaving Thasos he is said to have visited Sparta, but to have been at once banished from that city on account of his cowardice. His works, owing to their licentious character, were also prohibited by the Spartans. He next visited Siris, in lower Italy, a city of which he speaks very favourably. He then returned to his native place, and was slain in a battle against the Naxians by one Calondas or Corax, who was cursed by the oracle for having slain a servant of the Muses.

The writings of Archilochus consisted of elegies, hymns, —one of which used to be sung by the victors in the Olympic games,—and of poems in the iambic and trochaic measures. To him certainly we owe the invention of iambic poetry and its application to the purposes of satire. The only previous measures in Greek poetry had been the epic hexameter, and its offshoot the elegiac metre; but the slow measured structure of hexameter verse was utterly unsuited to express the quick, light motions of satire. Archilochus made use of the iambus and the trochee, and organised them into the two forms of metre known as the iambic trimeter and the trochaic tetrameter. The trochaic metre he generally used for subjects of a serious nature; the iambic for satires. He was also the first to make use of the arrangement of verses called the epode. Horace in his metres to a great extent follows Archilochus. All ancient authorities unite in praising the poems of Archilochus, in terms which appear to be somewhat exaggerated. His verses seem certainly to have possessed strength, flexibility, nervous vigour, and, beyond everything else, impetuous vehemence and energy. Horace speaks of the "rage" of Archilochus, and Hadrian calls his verses "raging iambics." By his countrymen he was reverenced as the equal of Homer, and statues of these two poets were dedicated on the same day. The fragments of Archilochus are to be found in the collections of smaller Greek poets by Jacobs, Bergk, and Gaisford, and have been published separately by Liebel, *Archilochi Reliquiæ*, Leipsic, 1812, 1818.

ARCHIMANDRITE (from μάνδρα, a fold, cloister, or convent), is a title in the Greek Church applied to a superior abbot, who has the supervision of several abbots and cloisters. The name has sometimes been applied generally to superiors of large convents. In Russia the bishops are selected from among the archimandrites. Although the title is peculiar to the Greek Church, it has found its way into Western Europe. It is used in Sicily, Hungary, and Poland, and has even been applied to bishops of the Latin Church.

ARCHIMEDES, the greatest mathematician and the most inventive genius of antiquity, was born at Syracuse, in Sicily, about 287 B.C. In his youth he went to Alexandria, and completed his education there under Conon, at the royal school of the Ptolemies, of which Euclid had been the ornament some half a century before. On his return to his native city he devoted himself to geometrical investigations, and by his great energy and inventiveness carried the science far beyond the limits it had then attained. Combined with his remarkable faculty of analysis was a power of practical application which enabled him to establish the science of engineering upon a solid mathematical basis. Of the facts of his private life we have but a few disconnected notices. He was the devoted friend, and, according to some accounts, the relative of Hiero, king of Syracuse; and he was ever ready to exercise his ingenuity in the service of his admirer and patron. Popularly, Archimedes is best known as the inventor of ingenious contrivances, though many of the stories handed down about these are probably fabulous. He devised for Hiero engines of war, which almost terrified the Romans, and which protracted the siege of Syracuse for three years. There is a story that he constructed a burning mirror which set the Roman ships on fire when they were within a bow-shot of the wall. This has been discredited because neither Polybius, Livy, nor Plutarch mention it; mirrors may, however, as Buffon showed, be so arranged as to burn at a considerable distance, and it is probable that Archimedes had constructed some such burning instrument, though the connection of it with the destruction of the Roman fleet is more than doubtful. Among the most celebrated of his contributions to practical science are his discoveries in hydrostatics and hydraulics. The account usually given of one of these is remarkable. Hiero, it is said, had set him to discover whether or not the gold which he had given to an artist to work into a crown for him had been mixed with baser metal. Archimedes was puzzled till one day, as he was stepping into a bath and observed the water running over, it occurred to him that the excess of bulk occasioned by the introduction of alloy could be measured by putting the crown and an equal weight of gold separately into a vessel filled with water, and observing the difference of overflow. He was so overjoyed when this happy thought struck him that he ran home without his clothes, shouting, "εὕρηκα, εὕρηκα,"—I have found it, I have found it. It may have been this that led to his establishing the fundamental principle still known by his name, that a body immersed in a liquid sustains an upward pressure equal to the weight of the liquid displaced. Among a number of other mechanical inventions ascribed to him, the water-screw may be mentioned, which still bears his name. His estimate of the capabilities of the lever is expressed in the saying attributed to him, Δὸς ποῦ στῶ, καὶ τὴν γῆν κινήσω, "Give me a fulcrum on which to rest, and I will move the earth."

The life of this philosopher ends with the capture of Syracuse by Marcellus, 212 B.C. In the general massacre which followed the fall of the city, Archimedes, while engaged in drawing a mathematical figure on the sand, was run through the body by a Roman soldier. No blame attaches to the Roman general, Marcellus, since he had given orders to his men to spare the house and person of the sage; and in the midst of his triumph he lamented the death of so illustrious a person, directed an honourable burial to be given him, and befriended his surviving relatives. In accordance with the expressed desire of the philosopher, his tomb was marked by the figure of a sphere inscribed in a cylinder—the discovery of the relation between the volumes of a sphere and its circumscribing cylinder being regarded by him as his most valuable achievement. When Cicero was quæstor in Sicily (75 B.C.), he found the tomb of Archimedes, near the Agrigentine gate, overgrown with thorns and briers. "Thus," says Cicero (*Tusc. Disp.* v. 23), "would this most famous and once most learned city of Greece have remained a stranger to the tomb of one of its most ingenious citizens, had it not been discovered by a man of Arpinum." The range and importance of the scientific labours of Archimedes will be best understood from a brief account of those writings which have come down to us; and it may be remarked that though some useful and important works may have perished, it is probable that these are chiefly details of his mechanical inventions, and that all his most valuable mathematical discoveries have been preserved. The following treatises have escaped the ravages of time:—

(1.) *On the Sphere and Cylinder* (περὶ τῆς σφαίρας καὶ τοῦ κυλίνδρου). This treatise consists of two books, dedicated to Dositheus, and containing a number of propositions relative to the dimensions of spheres, cones, and cylinders, all demonstrated in a strictly geometrical method. The first book contains fifty propositions, the most important of which are:—Prop. XIV. on the measure of the curve surface of a cylinder; Props. XV. and XVI. on the surface of a cone; Prop XVII. of a frustrum of a cone; Prop. XXII. of a circle; Prop. XXXV. of the surface of a sphere; and Prop. XXXVII. of the relation between a sphere and its circumscribing cylinder. The second book contains ten propositions, which chiefly relate to plane spherical sections.

(2.) *The Measure of the Circle* (κύκλου μέτρησις) is a short book of three propositions. Prop. I. proves that the area of a circle is that of a triangle whose base is equal to its circumference, and height equal to its radius; Prop. II. shows that the circumference of a circle exceeds three times its diameter by a small fraction, which is less than $\frac{10}{70}$ and greater than $\frac{10}{71}$; and Prop. III. that a circle is to its circumscribing square nearly as 11 to 14. He arrived at these wonderfully accurate results by inscribing in and circumscribing about a circle two polygons, each of 96 sides; and, assuming that the perimeter of the circle lay between those of the polygons, he obtained by actual measurement the limits he has assigned.

(3.) *Conoids and Spheroids* (περὶ κωνοειδέων καὶ σφαιροειδέων) is a treatise in forty propositions, on the superficial and solid dimensions of the solids generated by the revolutions of the conic sections about their axes.

(4.) *On Spirals* (περὶ ἑλίκων), is a book, in twenty-eight propositions, upon the properties of the curve now known as the spiral of Archimedes, which is traced out by a radius vector, whose length is proportional to the angle through which it has turned from the initial position.

(5.) *Equiponderants and Centres of Gravity* (περὶ ἐπιπέδων ἰσορροπικῶν ἢ κέντρα βαρῶν ἐπιπέδων). This consists of two books, and may be called the foundation of theoretical mechanics, for the previous contributions of Aristotle were comparatively vague and unscientific. In the first book there are fifteen propositions, with eight postulates; and demonstrations are given, much the same as those still employed, of the centres of gravity—(1) of any two weights, (2) of any parallelogram, (3) of any triangle, (4) of any trapezoid. The second book is devoted to the finding the centres of gravity of parabolic segments.

(6.) *The Quadrature of the Parabola* (Τετραγωνισμὸς παραβολῆς) is a book in twenty-four propositions, demonstrating that the area of a parabola is $\frac{2}{3}$ of the triangle having its double ordinate for base and abscissa for height. His method of arriving at this result is most interesting, as being a sort of rude approximation to the modern process of area summation by integration. The expedients to which he resorted to avoid the idea of infinity are no less curious than they are admirable.

(7.) *On Bodies floating in Liquids* (Περὶ τῶν ὕδατι ἐφισταμένων), is a treatise in two books, on the principles of floating, and the positions of equilibrium of floating parabolic conoids.

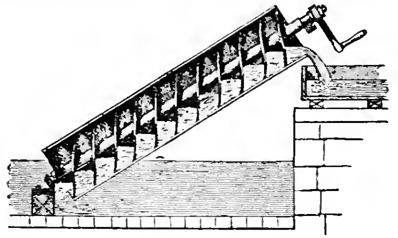
(8.) *The Psammites* (ὁ ψαμμίτης, Lat. *Arenarius*, or sand counter), a small treatise, dedicated to Gelo, the eldest son of Hiero, on arithmetical numeration, applied to reckoning grains of sand, is curious as containing the germ of the modern system of logarithms.

(9.) *A collection of Lemmas*, consisting of fifteen propositions in plane geometry. This has come down to us through a Latin version of an Arabic manuscript, and its authenticity has been questioned.

In the edition of Archimedes, published by Revault at Paris in 1615, the following works are said to be lost:—On the *Crown of Hiero*; on the *Cochleon, or Water-Screw*; on the *Helicon, or Endless Screw*; on the *Trispaston, or Combination of Wheels and Axles*; on the *Machines employed at the Siege of Syracuse*; on the *Burning Mirror*; on the *Machines moved by Air and Water*; and on the *Material Sphere*. We do not know, however, that he ever committed accounts of his mechanical inventions to writing.

The *Edito princeps* of the works of Archimedes, with the commentary of Eutocius, is that printed at Basil, in 1544, in Greek and Latin, by Hervagius. A Latin translation of them was published by Isaac Barrow in 1675 (London, 4to). Nicholas Tartalea (a celebrated algebraist), published in Greek and Latin the treatises on the *Centre of Gravity*, on the *Quadrature of the Parabola*, and on *Floating Bodies* (Venice, 1543). Frederic Commandine edited the beautiful Aldine edition of 1558, 4to, which contains *Circuli Dimensio, De Lineis Spiralibus, Quadratura Paraboles, &c., Conoidibus et Spheroidibus*, and *De numero Arenæ*; and in 1565 the same mathematician published the two books *De iis quæ vehuntur in Aquâ*. The most complete and magnificent edition of the works is that edited by Torelli, and published with the commentaries of Eutocius at Oxford, in 1792, folio. The most valuable edition of the *Arenarius*, which is also the first modern translation of any part of Archimedes, is that published in English by Anderson (London, 1784), with useful notes and illustrations. The first modern translation of the works is the French edition published by F. Peyrard (Paris, 1808, 2 vols. 8vo). A German translation, by Nizze, was published at Stralsund in 1824, and another by Gutenäcker, at Wurzburg, 1828, 8vo. See *Quart. Rev.*, vol. iii. p. 89; Plutarch's *Life of Marcellus*; Pope Blount's *Censura Celebrium Authorum* (London, 1690); the *Arenarius of Archimedes*, Oxford, 1837; *Ed. Rev.*, vol. xi. p. 185; Powell's *History of Natural Philosophy* (Lardner's Cycl.), p. 40.

ARCHIMEDES, Screw of, a machine for raising water, said to have been invented by Archimedes, for the purpose of removing water from the hold of a large ship that had been built by King Hiero. It consists of a water-tight cylinder, enclosing a chamber walled off by spiral divisions running from end to end, inclined to the horizon, with its lower open end placed in the water to be raised. A section of it is shown in the accompanying woodcut. The water, while occupying the lowest portion in each successive division of the spiral chamber, is lifted mechanically by the turning of the machine. Another form of the



Screw of Archimedes.

screw has the spiral revolving free in a fixed cylinder, but neither of the machines is now much used.

ARCHIPELAGO, a name which, though it is now applied to any island-studded sea, was formerly the distinctive designation of what, though still known as the Archipelago, is often distinguished as the Grecian Archipelago, namely, that part of the Mediterranean which lies between Greece and Thessaly on the W. and Asia Minor on the E.—the Ægean Sea (Αἰγαῖον Πέλαγος) of the ancients. Several etymologies of the name have been proposed, as—(1), It is a corruption of the ancient name; (2), it is from the modern Greek, Ἅγιο Πέλαγο, the Holy Sea; (3), it arose at the time of the Latin empire, and means the Sea of the Kingdom (*Arche*); (4), it is a translation of the Turkish name, Ak Degniz, *Argon Pelagos*, the White Sea; (5), it is simply *Archipelagus*, the Chief Sea.

The Grecian Archipelago abounds in islands, of which the following are the chief:—Thaso, near the Rumelian (*Thracian*) coast, opposite the mouth of the Karasu (*Nestus*); Samothraki, fronting the Gulf of Sares; Imbro and Lemnos, in prolongation of the peninsula of Gallipoli (*Chersonesus Thracica*); Skiathos, Skopelo, Celadroni, Peristeria, &c., running out from the southern extremity of the Thessalian coast; Negropont (*Eubœa*), the largest of all, along the east coast of Greece; Skyros, with its satellites, east of Negropont; Mitylene (*Lesbos*) and Chios, off Asia Minor; Samo and Nikari (*Icaria*), in prolongation from Cape St Maria (*Mycale Pr.*); Stancho (*Cos*, ἐσ-τὰν-Κῶ), in the Gulf of Cos, with Kalymno to the north; and finally, the great group of the Cyclades, of which the most important are Andros, Tenos, Myconos, and Delos, in prolongation of Eubœa, Zea (*Ceos*), and Cythnos, running out from the south of Attica, and Melos, Kimolos, Siphnos, Antiparos, Paros, Naxos, Amorgos, Astynactea, forming a curve, from west to east, with its convexity to the north, while to the south are a number of smaller islands. This profusion gives beauty and picturesqueness to the sea, but renders its navigation difficult and dangerous, notwithstanding the large number of safe and commodious gulfs and bays. Many of the islands are of volcanic formation; while others, as Paros, are mainly composed of pure white marble. The larger islands have some very fertile and well-watered valleys and plains. The chief productions are wheat, wine, oil, mastic, figs, raisins, honey, wax, cotton, and silk. The people are employed in fishing for coral and sponges, as well as for bream, mullet, and other fish. The men are hardy, well built, and handsome; and the women are noted for their beauty, the ancient Greek type being well preserved. The Cyclades belong to Greece; most of the other islands to Turkey.

The other Archipelagoes, portions of ocean with numerous islands in close contiguity, as the Indian, Caribbean, Patagonian, &c., will be described in their respective places.

ARCHITECTURE

ARCHITECTURE (Latin *architectura*, from the Greek ἀρχιτέκτων, a master-builder) is the art of building according to principles which are determined, not merely by the ends the edifice is intended to serve, but by considerations of beauty and harmony. It cannot be defined as the art of building simply, or even of building well. The end of building as such is convenience, use, irrespective of appearance; and the employment of materials to this end is regulated by the mechanical principles of the constructive art. The end of architecture as an art, on the other hand, is so to arrange the plan, masses, and enrichments of a structure as to impart to it interest, beauty, grandeur, unity, power. Architecture thus necessitates the possession by the builder of gifts of imagination as well as of technical skill, and in all works of architecture properly so called these elements must exist, and be harmoniously combined. The combination of technical with imaginative features removes architecture from the precise position occupied by painting, sculpture, and music, but does this more in appearance than in reality, since the greatest works of the architect must always be those in which the imagination of the artist is most plainly seen.

Like the other arts, architecture did not spring into existence at an early period of man's history. The ideas of symmetry and proportion which are afterwards embodied in material structures could not be evolved until at least a moderate degree of civilisation had been attained, while the efforts of primitive man in the construction of dwellings must have been at first determined solely by his physical wants. Only after these had been provided for, and materials amassed on which his imagination might exercise itself, would he begin to plan and erect structures, possessing not only utility, but also grandeur and beauty. Before proceeding to inquire into the history of architecture, it may be well to enumerate briefly the elements which in combination form the architectural perfection of a building. These elements have been very variously determined by different authorities. Vitruvius, the only ancient writer on the art whose works have come down to us, lays down three qualities as indispensable in a fine building, viz., *Firmitas, Utilitas, Venustas*, stability, utility, beauty. In an architectural point of view the last is the principal, though not the sole element; and, accordingly, the theory of architecture is occupied for the most part with æsthetic considerations, or the principles of beauty in designing. Of such principles or qualities the following appear to be the most important: size, proportion, harmony and symmetry, ornament, and colour. All other elements may be reduced under one or other of these heads.

Elements of architectural perfection.

Size.

With regard to the first quality, it is clear that, as the feeling of power is a source of the keenest pleasure, size, or vastness of proportion, will not only excite in the mind of man the feelings of awe with which he regards the sublime in nature, but will impress him with a deep sense of the majesty of human power. It is, therefore, a double source of pleasure. The feelings with which we regard the Pyramids of Egypt, the vast monoliths at Rome, the massive temples of Sicily and the Parthenon, and the huge structures of Stonehenge, sufficiently attest the truth of this principle.

The qualities in the general disposition of the parts of a building which are calculated to give pleasure to the beholder, are proportion, harmony, and symmetry. To obtain a clear idea of the general plan in order to appreciate these qualities, the best method is to contemplate the building under conditions that prevent the mind from being disturbed by the consideration of the details—at a distance, for instance, or by moonlight, when its outlines may be seen standing boldly out against the sky. Thus the mass of a Gothic cathedral, the proportion of its parts, the outline of tower, nave, choir, and lady-chapel, the deep shadows which show the projection or recess of its various parts, are in themselves beautiful even when there is not light enough to distinguish mouldings, carvings, or tracery.

Proportion.

Proportion itself depends essentially upon the employment of mathematical ratios in the dimensions of a building. It is a curious but significant fact that such proportions as those of an exact cube, or of two cubes placed side by side—dimensions increasing by one-half (*e.g.*, 20 feet high, 30 wide, and 45 long)—or the ratios of the base, perpendicular, and hypotenuse of a right-angled triangle (*e.g.*, 3, 4, 5, or their multiples)—please the eye more than dimensions taken at random. No defect is more glaring or more unpleasant than want of proportion. The Gothic architects appear to have been guided in their designs by proportions based on the equilateral triangle.

Harmony.

By harmony is meant the general balancing of the several parts of the design. It is proportion applied to the mutual relations of the details. Thus, supported parts should have an adequate ratio to their supports, and the same should be the case with solids and voids. Due attention to proportion and harmony gives the appearance of stability and repose, which is indispensable to a really fine building. Symmetry is uniformity in plan, and, when not carried to excess, is undoubtedly effective. But a building too rigorously symmetrical is apt to appear cold and tasteless. Such symmetry of general plan, with diversity of detail, as is presented to us in leaves, animals, and other natural objects, is probably the just medium between the excesses of two opposing schools.

Symmetry.

Ornament.

Next to general beauty or grandeur of form in a building comes architectural ornament. Ornament, of course, may be used to excess, and, as a general rule, it should be confined to the decoration of constructive parts of the fabric; but, on the other hand, a total absence or a paucity of ornament betokens an unpleasing poverty. Ornaments may be divided into two classes—mouldings and the sculptured representation of natural or fanciful objects. Mouldings, no doubt, originated, first, in simply taking off the edge of anything that might be in the way, as the edge of a square post, and then sinking the chamfer in hollows of various forms; and thence were developed the systems of mouldings we now find in all styles and periods. Each of these has its own system; and so well are their characteristics understood, that from an examination of them a skilful architect will not only tell the period in which any building has been erected, but will even give an estimate of its probable size, as professors of physiology will construct an animal from the examination of a single bone. Mouldings require to be carefully studied, for nothing offends an educated eye like a confusion of mouldings, such as Roman forms in Greek work, or Early English in that of the Tudor period. The same remark applies to sculptured ornaments. They should be neither too numerous nor too few, and, above all, they should be consistent. The carved ox skulls, for instance, which are appropriate in a temple of Vesta or of Fortune, would be very incongruous on a Christian church.

Colour.

Colour must be regarded as a subsidiary element in architecture, and although it seems almost indispensable and has always been extensively employed in interiors, it is doubtful how far external colouring is desirable. Some contend that only local colouring, *i.e.*, the colour of the materials, should be admitted; but there seems no reason why any colour should not be used, provided it be employed with discretion and kept subordinate to the form or outline. This subject is of too much importance to be dismissed summarily here, and will be treated in a supplementary notice at the end of this article.

Rise and progress of the art. As has been already pointed out, the origin of the art is to be found in the endeavours of man to provide for his physical wants. A picturesque account of the early stages in its progress is given by Vitruvius. According to him, man in his primitive savage state began to imitate the nests of birds and the lairs of beasts, and constructed arbours with twigs of trees. To these arbours succeeded huts with walls composed of dried turf, strengthened with reeds and branches. From huts to houses the progress is gradual and easy. Other writers have endeavoured to trace three orders of primitive dwellings—the cave, the hut, and the tent—constructed severally by the tribes who devoted themselves to hunting and fishing, to agriculture, and to a pastoral and nomadic life. There can be no doubt that climate and surrounding circumstances affected not only the form of the primitive, buildings but also the materials employed. Thus, where trees abounded, stone was probably a material seldom used, as it entailed a much greater amount of labour than timber; but as stone would neither burn nor rot, it was preferred for all durable purposes. Where wood was plentiful, as in Greece and in Lycia, stone architecture exhibits traces of an original timber construction. The columns were originally posts, and the architraves and triglyphs beams resting on each other. The Lycian tomb in the British Museum furnishes a strong proof that there the art of the carpenter preceded that of the mason, and suggested forms, which became conventional, and from which the latter could not venture to depart. On the other hand, in the plains of Egypt, where building timber is scarce, and where there is abundance of large stone in the mountains, the mason element seems to have prevailed. In such plains as those of Nineveh and Babylon artificial stone was made from lumps of dried or burnt clay. Finally, in vast sandy deserts, where there are neither trees nor stones, the skins of beasts, sewed together and supported by sticks, formed the earliest shelter. This soon grew into the tent, and its form still influences the architecture of the Chinese and the Tartars. Much ingenuity has been expended in the inquiry whether it was timber or stone that first gave birth to the art of *architecture;* the probability is, that the hut, the cairn, and the tent, all contributed their share in different countries.

No traces remain of the steps by which the beautiful temples of Egypt or the magnificent halls of Persia and Assyria were developed from these rude beginnings. The earliest known structures of those countries belong to an age already considerably advanced in civilisation and in the art of construction. And the history of architecture from its earliest specimens in Egypt is not one continuous line of progress. We can indeed show how from these early structures sprang the art of Greece; how that was modified by the Romans; and finally, how the Pointed architecture of the 13th century arose. But the development is not gradual; it proceeds by a series of steps, and one style does not shade imperceptibly into another. No doubt the architects of each country borrowed somewhat (in detail more especially) from the designs of the adjacent countries; but, nevertheless, each country originated forms peculiar to itself, and in all its artistic efforts continued to repeat and elaborate them. So definite are the characteristics of the styles of different nations, that from the mere form, carving, or decoration of any structure, its age and its architects can, usually, be fairly determined.

PREHISTORIC STRUCTURES.

The numerous relics of structures left by primeval man have generally little or no architectural value. The only interesting problem regarding them, the determination of their date and purpose, and of the degree of civilisation which they manifest, falls within the province of archæology.

The principal specimens of such prehistoric erections may be classified thus—

(1.) *Monoliths* (*Maenhir*, from *Maen*, a stone, *hir*, high), or single upright stones (fig. 1). The best example is at Carnac, in Brittany. This huge stone, when perfect, was 63 feet high, and 14 feet in diameter at its widest part. It is rudely shaped to a circular form, and weighs about 260 tons.

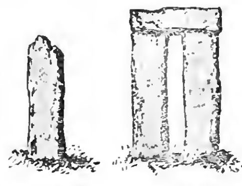


FIG. 1.—Maenhir and Trilithon.

(2.) *Cromlechs*, table-stones, generally consisting of one large flat stone supported by others which are upright (fig. 2). The cromlech is also named *Dolmen*, from *Taal*, or *Daul*, a table, and *Maen*, a stone. A good example of the cromlech is the structure known as "Kit's Coity House," near Maidstone. Other examples occur in different parts of Great Britain and Ireland, and numerous specimens are found in Algeria, in India, in the country east of the Jordan, in Guernsey, and near Saumur, on the Loire.

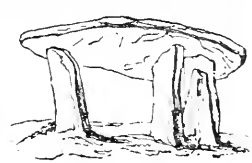

FIG. 2.—Dolmen.

(3.) *Circles of Stone.*—The most important specimen of these in Britain is Stonehenge (fig. 3). Others are found at Avebury, in Wiltshire (fig. 4); at Stanton Drew, in Somersetshire; at Stennis, in Orkney; and at Callernish, in Lewis; and several have been discovered in the districts around Mount Sinai and Aden. In some circles, as at

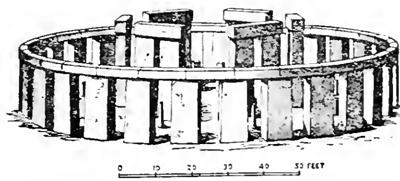

FIG. 3.—Stonehenge (restored, after Inigo Jones).

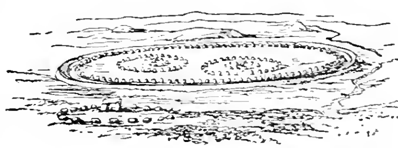

FIG. 4.—Circles of Avebury (restored). From Waring's *Stone Monuments*.

Stonehenge, as well as separately, are found trilithons (fig. 1), which appear to be a modification of the dolmen.

(4.) *Tumuli.*—These include the *beehive huts*, so called from their shape, found scattered throughout Cornwall, Wales, and Scotland (fig. 5). Similar, but superior, edifices are to be met with in Ireland; and of these, New Grange, near Drogheda, apparently a burial mound, is the finest specimen (fig. 6). The design of the

FIG. 5.—Beehive Hut, Lewis. From Waring.

FIG. 6.—Section of chambered Burial Mound, New Grange, Ireland. From Waring.

FIG. 7 —"Nurhag," near Isili, Sardinia. From Waring.

"nurhags" (fig. 7), which are found in great numbers in the island of Sardinia, has greatly puzzled archæologists. It has been conjectured that they were sepulchres, the dead

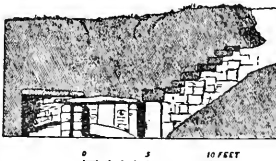

FIG. 8.—Section of Pict's House, Pierowall, Orkney. From *Archæologia*, vol. xxxiv. pl. 17.

being exposed on their summits. Of the so-called "Picts' houses" of the Orkney Islands, some are chambered tumuli, while others may be more properly described as underground dwellings (fig. 8).

(5.) *Wooden huts*, the submerged remains of which have been recently discovered in the lakes of Switzerland, as well as in Sweden, in Italy, and in Ireland. These erections, which rose on piles just above the surface of the water, present no features of architectural interest.

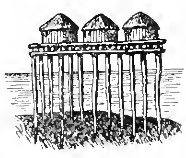

FIG. 9.—Lake Dwellings, or Crannoges, Lake Ardakillin, Roscommon. From Troyon's *Hab. Lacustres*, 1860.

A specimen of prehistoric sculpture, on stone, taken

FIG. 10.—Ancient Swiss Lake Dwellings. From Troyon's *Hab. Lacustres*, 1860.

from ruins in the island of Gozo, in the Mediterranean, is given in fig. 11.

Prehistoric remains are separated by a wide gulf from those which now fall to be noticed, inasmuch as, whether or not they led, by improvement in their forms, to anything really architectural, no evidence remains of such progress, and they must therefore be regarded as practically dissociated from anything that we have now to describe.

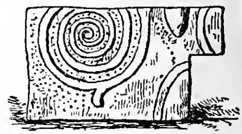

FIG. 11.—Ornaments on stone, Gozo. From Waring.

EGYPTIAN ARCHITECTURE.

For the beginnings of the art—its earliest efforts, grand even in their infancy—we must turn to Egypt.

A short description of the general configuration of the country may be useful here. Its habitable land is a narrow strip a few miles wide, extending from the Nile, on one or both its banks, to the rocks or desert. About 100 miles up the river is Cairo, and close to it Memphis, the old capital of Lower Egypt, Heliopolis, and the great pyramids of Ghizeh, Abooseer, Sakkara, and Dashour; 450 miles higher up the river is the site of the great Thebes, with Karnak and Luxor on the right or eastern bank, and Medinet Haboo on the west. Beyond this in succession are Esne, Edfoo, Elephantina, Syene, and Philæ, close to the first cataract. Higher up (in Nubia) are the great caves of Aboosimbel, and at a still greater distance the pyramids of Meroë, or Dankelah. The rock is generally limestone up to Thebes, sandstone and breccia to Syene, where the well-known variety of granite, with hornblende, is found; these with the addition of unburnt brick, are the chief materials used in the construction of the Egyptian architectural monuments. The granite was principally supplied by the quarries at Elephantina and Syene, for which the Nile offered a ready mode of conveyance, although it appears that the obelisks and other enormous blocks were sent by land. Some species were brought down the river from Ethiopia, but we do not find that the materials were brought from any other foreign country. It may be remarked, too, that in the earliest structures the common *grès* or sandstone is principally employed. Excepting the obelisks and some few of the propylæa, all the temples at Thebes are of that material. In Lower Egypt, on the contrary, and in the works of later date generally, almost everything is constructed of granite.

It seems quite certain that Egyptian art is original and not derived from that of India; and it may be concluded with great probability that the structures of Egypt are the oldest specimens of architecture in the world. The origin of the structures themselves has been matter of some discussion. By several writers it has been thought that the rock-cut caves of Upper Egypt were the earliest efforts of architectural design, and furnished models for the enormous piles raised along the banks of the Nile. An examination of these caves, however, will show clearly that the very reverse is the case, and that the carvings of the excavations are imitated from the above-ground buildings.

The oldest works of the Egyptians, according to Herodotus, were the embankment of the Nile by Menes, the foundation of the city of Memphis, and the commencement of a temple to Vulcan. Next we learn from Manetho, as cited by Eusebius, that Venephes, the fourth king of the first dynasty, built some pyramids at a place called Cochomen, but this is all we know of them. Eusebius further records that Tosorthus, or Sosorthus, the second king of the third dynasty, found out how to build with polished or smooth stone (*καὶ τὴν διὰ ξεστῶν λίθων οἰκοδομὴν εὕρετο*).

Great Pyramid.

The next structure of which we have notice is the Great Pyramid, the most gigantic work in the world—one which never has been, and perhaps never will be surpassed. At this time the Egyptians must have reached a proficiency in the mechanical arts of which we can form no conception. They seem to have been able to quarry rocks of the hardest stone, even granite—to transport them to great distances—to raise huge blocks, vast monolith obelisks, that would puzzle our engineers with their best tackle—and, more wonderful still, they appear to have had the power not only of polishing granite, but of carving on that most stubborn material with the utmost facility, large surfaces and even huge statues being covered with hieroglyphics of the most minute kind and of the highest finish. It is impossible to discover how this was done, for though Herodotus (ii. 124, 125) tells us they had iron tools, it was long before the conversion of that metal into steel had been found out; and with all the best modern tools of steel, it is difficult and costly to carve even plain letters in granite. According to the account of Herodotus, the occasion of the erection of this great work was the caprice of a king, Cheops, who is supposed to be the Suphis of Syncellus, and the Chembes of Diodorus. This king was a tyrant of the very worst kind; he closed all the temples throughout Egypt, forbade every sort of religious observance, and forced all his subjects to labour for him as he pleased. Among other whims, he determined to build this pyramid as a tomb for himself. The stones were quarried in the Arabian mountains, and none were less than 30 feet long. They were then conveyed by the Nile to a newly-constructed road, three-quarters of a mile long, 60 feet broad, and in a cutting of 48 feet. This road, of polished stone, and carved with figures, took ten years to complete. Twenty years were spent in building the pyramid itself.

The site of this extraordinary structure is at Ghizeh, in the neighbourhood of Cairo. The base was, Herodotus tells us, 8 plethra (about 808 English feet) square, and the height the same. This, however, is not the case, the Greek author having probably measured the sloping edge. The dimensions are variously given by the various persons who have measured it. M. Nouet, who was of the French commission in Egypt, and had perhaps the best means of ascertaining the truth, states its base to be a square whose side is 716 French or 768 English feet, and gives the height as 421 French or 452 English feet. The dimensions of the pyramid in its original state, as given by Colonel Vyse, are 764 feet length of base, 720 feet slant side, and 480 feet high. According to Sir Henry James (*Notes on the Great Pyramid*, 1869), the side of the base is 760 feet; while Professor Piazzi Smyth gives this as 763·81, and the height as 486·2567. The pyramid thus covers upwards of 13 acres, and is about 150 feet higher than St Paul's cathedral. As compared with the largest building in the world, St Peter's, Rome, the Great Pyramid covers an area which is as 58 to 22, or nearly three times as much, and is 50 feet higher. Like almost all the other pyramids, its sides face the cardinal points, and it is entered from the north by a descending passage, which leads to a few small chambers or cells, the largest of which is but 17·7 feet wide. In one of these a solitary sarcophagus was found. The pyramid appears to be a solid mass of stone, and is built in regular courses or layers, which vary in thickness from 2 to 5 feet, each receding from the one below it to the number of 202; though even this is variously stated from that number to 260, as indeed the height is given by various modern travellers at from 444 to 625 feet. And the ancient writers differ as widely both among themselves and from the moderns. On the top course the area is about 10 English feet square, though it is believed to have been originally two courses higher, which would bring it to the smallest that in regular gradations it could be. This vast erection, on which the labours of 100,000 men were bestowed for twenty years, and which contains 85 millions of cubic feet of stone, must have cost (reckoning quarrying, transport—twice by land and once by river—squaring, hoisting, and setting at 2s. per foot) something like $8\frac{1}{2}$ millions of English money.

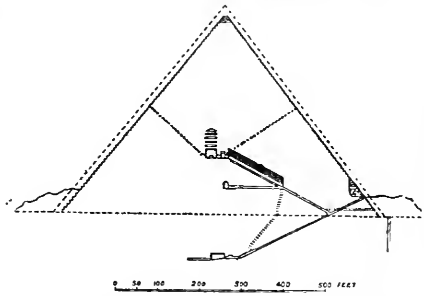

FIG. 12.—Section of Great Pyramid. From Vyse's *Pyramids of Ghizeh.*

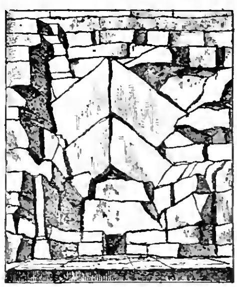

FIG. 13.—Entrance to Great Pyramid of Gizeh.

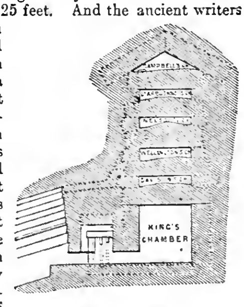

FIG. 14.—Part Section of Great Pyramid. From Vyse.

Other pyramids. A second pyramid, close to the first, was built by the successor of Cheops, whom Herodotus calls Chephren; the inscriptions on the stones, however, give the name Shafra. The side of its base is about 60 feet less than that of the former. About forty years later, Mycerinus, or Mencheres, built a third; but the side of the base is only about 364 feet, or less than half that of the Great Pyramid. It was, however, entirely faced with polished granite, while the others were of limestone. A statue of King Chephren has recently been found in a temple close adjacent to the pyramids, and now forms one of the most remarkable objects in the museum at Cairo. Canina (*Architectura Antica*, part i.) has described altogether twenty large and twenty-seven small pyramids, some not more than 30 feet square. But the researches of Lepsius and others prove that the number is much greater than this, and on the range of cliffs overlooking the Nile, from Aboorwash in the north to Illahoon in the south, the number is probably not under 100.

Design and construction of the pyramids. A great deal of trouble has been taken to discover the principles on which the Egyptians planned these erections. The most reasonable theory is that each side was meant for an equilateral triangle, four of which, laid sloping and brought to a point, would compose the pyramid; but neither the dimensions nor the angles agree with this. It is true that the sides of the three great pyramids have an angle with the horizon of from 51½° to 52½° or thereabouts; but those at Abooseer and at Sakkara, as given by Canina, measure 55°, while at Barkal, near Meroë, the angle is no less than 72°. At Dashour the pyramid has a slope about half way up of 53°, which afterwards is flattened to 44°. At Meydoum there is a pyramid in three great steps. If,

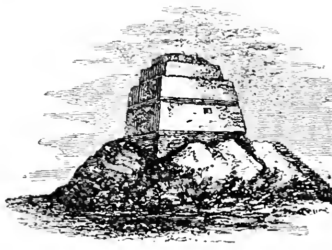

FIG. 15.—Pyramid of Meydoum. From Vyse.

therefore, the Egyptians had begun to work on the above theory, they departed from it in many notable instances.

The following seems to have been the manner in which the pyramids were generally constructed. A level platform was cut in the rock, a portion of which was, however, left in the centre above the general level to serve as a sort of core to the pyramid. A deep chamber was then sunk in the rock, with a passage leading from it always on the north side, and usually at an angle of 26° to 28°, to the surface of the ground. It is curious that these passages were almost always of one dimension, viz., 3 ft. 5 in. wide, and 3 ft. 11 in. high. Over the chamber was built a mass of masonry, which was gradually added to at the side and top, according to the power, or the wealth, or the length of life of the founder. Finally, the angles of the stones were cut off to the proper slope, or a casing added, and the pyramid thus completed from the top. Some of the casings were highly finished. Those of the first and second pyramid were of polished stone; that of the third was of polished granite. Occasionally, as in the Great Pyramid, and in the southern one at Dashour, there was a chamber built above the one which was cut in the rock. Their entrances were carefully concealed, and even the doors of the chamber defended by gigantic portcullises of granite, some 8 to 10 feet square, weighing 50 to 60 tons, so as to render the security of the chambers as great as possible. Yet every chamber in the chief pyramids, at least, except perhaps "the false one" at Meydoum, has been rifled ages ago, and so the great purpose of their erection utterly set at nought. Most of the sarcophagi which they once contained have also been carried away. One, that of Mycerinus, was lost in its passage to England; but the mummy-case and mummy which it contained are now in the British Museum. The sarcophagus of the Great Pyramid still rests in its chamber. An extra interest belongs to the third pyramid (of Mycerinus) owing to its chamber being ceiled with a pointed arch. But it is not a true arch, the stones being merely strutted against each other, as over the entrance to the Great Pyramid (see fig. 13 *supra*), and the underside cut to the above form. The chamber of a pyramid at Sakkara was lined with blue and white tiles like the Dutch style; and at the false one at Meydoum there is, about two-thirds up, a band about 12 feet wide, left rough all round, and it has been supposed that this may have been left as a ground for decoration. But there is nothing to prove this. Herodotus, however, expressly says that the exterior was richly sculptured, and a model of a pyramid that is to be seen at the Museum of Cairo bears out his statement. The construction of pyramids seems to have ended in Lower Egypt at a very early date, with the old dynasty of Memphis. But some of crude brick, and containing arched chambers, are found at Thebes, and are supposed to be of date about 1200 B.C. Many similar structures, but on a very much smaller scale, were erected in Ethiopia and Meroë down to about 700 B.C.

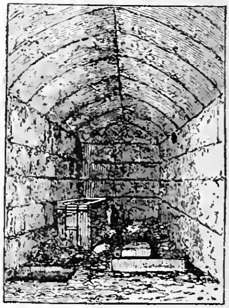

FIG. 17.—Sepulchral Chamber, Third Pyramid. From Vyse.

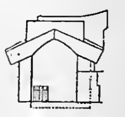

FIG. 18.—Section of Sepulchral Chamber, Third Pyramid. From Vyse.

Many theories have been stated as to the purposes for which these gigantic monuments were erected, but the opinion of M. Mariette, the latest, as well as one of the most learned writers, may be taken as correct, viz., that every pyramid was a tomb and the gigantic enclosure of a mummy. It is certain that every pyramid is on the western bank of the Nile, the region of the setting sun, and thus associated by the Egyptians with the regions of death, and that each group of pyramids is the centre of a necropolis

Next to the pyramids in massive grandeur comes the Great Sphinx, and an additional interest has lately been associated with this statue, from the finding of an inscription, which seems to prove that it was sculptured before the time of the builder of the first pyramid. The Egyptian sphinx was quite different from the Greek, which usually had a female head on the body of a winged lion, whereas the Egyptian was wingless, and had usually the head of a man, bearded and capped, and thus represents strength and wisdom. Those with the head of a ram, or crio-sphinxes, are supposed to be dedicated to Ammon (Jupiter Ammon); those with the head of a hawk are called hieraco-sphinxes, and are sacred to Ra, or the sun. The

FIG. 19.—Figures at Thebes.

Great Sphinx at Ghizeh has the body of a lion crouching close to the ground; the height from the floor, or platform on which it lies, to the top of the head is 100 feet: the total length is 146 feet; across the shoulders it measures 34 feet. The head, from the top to the chin, is 28 feet 6 inches, and is calculated to be 40,000 times the bulk of an ordinary human head. A small temple or sanctuary was built between its paws. With the exception of this, and the paws themselves, which are of masonry, the whole appears to be carved out of the solid rock. Indeed, it may safely be assumed to be solid; for Colonel Vyse drilled a hole 27 feet deep into the shoulder, and found that, so far at least, it was so.

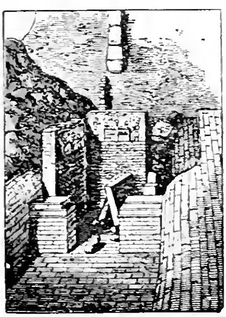

FIG. 20.—Temple between paws of Great Sphinx. From Vyse.

Serapeum.

Another grand memorial of the old dynasty must be mentioned, viz., the Serapeum, near the pyramid of Sakkara, discovered in 1851 by M. Mariette, and excavated 30 feet deep in the solid rock. It contains the mummies of the sacred bulls, placed in gigantic sarcophagi, 11 feet high, 7 to 8 feet wide, and 13 to 18 feet long, each of which is placed in a chamber. The chambers, forty in number, are excavated on each side of galleries about 12 feet wide, the ceilings being *cut* (not *built*) to the form of an arch.

No great distance beyond Sakkara, in the district called the Fayoom, was the famous Labyrinth, an immense mass of buildings mentioned by Herodotus as the palaces built for the twelve kings. From his description of it this appears to have been as great a work and as great a wonder as the pyramids themselves. It was close to Lake Mœris, and contained in the time he wrote 3000 chambers, half above and half below ground, besides immense halls, corridors, courts, gardens, &c. The roofs were wholly of stone, and the walls covered with sculpture. On one side stood a pyramid 40 orgyiæ, or about 243 feet high. It appears from the ruins that huge masses of buildings once occupied three sides of an open quadrangle, about 200 yards square in the inside—the two wings being about 300 yards long, and the third side about 400, measured on the outside. The pyramid, as stated by the various authorities, occupied the greater part of the fourth side, and measured about 348 feet square. There are a multitude of small chambers in two stories, as described by Herodotus, and Canina supposes there was a third story above these supported on columns—a sort of open gallery.

Tombs.

TOMBS.—The great reverence paid by the Egyptians to the bodies of their ancestors, and their careful preservation of them by embalmment, necessitated a great number and vast extent of tombs. Some of these, erected long after the building of pyramids had ceased, are built up above ground; others are caves cut in the sides of rocks; others are passages tunnelled under ground to a great extent. The tombs above ground have been for the most part destroyed. But some very interesting ones are found near the Great Pyramid. They are of well-squared stone, in the form of truncated pyramids; the tops are level, and they show no appearance of anything having been built above them. But there must have been a covering of some kind, as pits, leading to sepulchral chambers beneath, are cut down directly from the surface level. The most curious tomb at Ghizeh is known as Campbell's, of the supposed date of about 660 B.C. It is an open excavation, 53 ft. 6 in. deep, 30 ft. by 26 ft. 3 in. on plan, with niches, &c., leading out of it. In these were found four sarcophagi, one of which, of basalt, is in the British Museum. This excavation is supposed, from some indications left of a springing stone, to have been covered by an arch. If so, this would be the oldest known stone arch of a large size. In fact, it is difficult to imagine any other way in which this large excavation could have been covered. But the special object actually found was a tomb built up in the centre of the excavation, of good masonry,

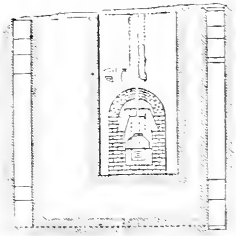

FIG. 21.—Campbell's Tomb; section looking west. From Vyse.

covered by three stones as struts, over which was a perfectly formed voussoired arch. This arch was destroyed not long ago by the Egyptian Government, in order to build a mill. Outside the whole excavation was a deep trench 5 ft. 4 in. wide, and 73 feet deep, from which branch out a number of chambers. This excavation was probably finished above with some such truncated pyramid as we have already described.

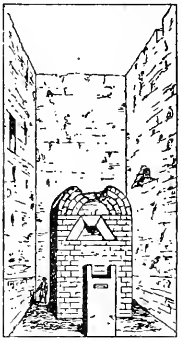

Fig. 22. Building in Campbell's Tomb. From Vyse.

Even more interesting are the tombs at Beni Hassan and Thebes. There is little attempt at architectural decoration in these, except the facade and some columns cut in the rock inside; but they are filled with the most interesting paintings, representing even the minutest incidents of private life. A model of one was exhibited in London by Belzoni; and there is a valuable series built up, and painted in fac-simile, in the Vatican at Rome. It appears that as soon as a king succeeded to the throne, the excavation of his tomb commenced, and proceeded year by year till his death. Canina has given plans and sections of several of the royal tombs, extending from 250 to 400 feet direct into the solid rock. Several of these tombs at Beni Hassan have external facades high up in the cliffs, consisting each of two columns *in antis*, to which we shall have again to refer when treating of the origin of the Grecian Doric. Others, as at Ghizeh and Sakkara, have their entrances level with or below the ground, and without external decoration; whilst others, as at Thebes, have their entrances high up in the face of the cliffs, and not only without ornament of any kind, but closed up as if for purposes of concealment. But each, no matter of what size or description, had one or more chambers or corridors, in the floor of some one or other of which was sunk a deep pit. Leading out of this pit, again, were other chambers, in one of which was deposited the sarcophagus. When this was done the pit was filled up so as to render the concealment of the place of sepulture as complete as possible. One of the grandest at Thebes is that of a priest, otherwise unknown to fame, which comprises a series of halls, passages, and chambers, at various levels, branching off in one place three different ways. In all, it is 862 feet long, and the part actually excavated occupies an area of 23,000 feet.

Many of the paintings already alluded to are often simply executed in colour, but others are emphasised by being sculptured also in slight intaglio. This came into use, it would seem, about the 14th century B.C., the earlier work being in relief. The stone was usually prepared for painting by being covered with a very thin fine stucco. Even the fine granites were so covered sometimes, and the woodwork also. Imitations of costly woods, &c., are to be found even at this early time.

Temples.

TEMPLES.—The Egyptian temples range from the time that Thebes became the capital (about 2000 B.C.) down to the time of the Cæsars.

Of all the temples, the most remarkable is perhaps the rock-cut one of Aboosimbel, in Nubia, supposed to have been excavated in the 14th century B.C. The façade was cut in the steep face of a rock, the entrance doorway being flanked by two gigantic statues (66 feet high) on each side. The main feature internally was a grand hall supported by two rows of detached piers, in front of each of which is a statue 17 ft. 8 in. high. Another remarkable temple exists at Ghizeh, built up within a great excavation in the rock; here was found the statue of Chephren before mentioned. The temple is lined with immense blocks of polished granite, as are also the piers, each of these being of one stone about 15 feet high, 5 feet wide, and 3·2 thick. Over this structure there was clearly another, above ground, as extensive remains of fine stone-walling still exist. This singular edifice is without inscription of any kind, and evidently was connected in some way with sepulture, as tomb-chambers lead out of it. The apparently great antiquity of these and other excavations lent countenance to the theory to which we have before alluded, viz., that the origin of Egyptian art is to be found in them. But the evidence before us distinctly shows that all the forms used in the great excavations at Aboosimbel, Thebes, Beni Hassan, and other places, are clearly copied from built buildings. Thus, we have the ceilings arched out of the solid rock, or formed with clear imitations of beams, squared or round, also cut out of the rock, just as square beams or round logs were used in ordinary buildings; and so with the other parts of the excavations.

The grandest architectural efforts of the Egyptians are shown in their built temples, whose construction ranges from the time at which Thebes became the chief capital (about 2000 B.C.) down to so late even as the time of the Cæsars. Sir Gardner Wilkinson, in his *Architecture of Ancient Egypt*, gives a very full account of these edifices, and classifies them thus:—1. *Sanctuary Temples*, or those with only one single chamber. 2. *Peripteral Temples*, or the like, but surrounded with columns. 3. *Temples in Antis*, with a portico of two or four columns in front. 4. Those with porticos of *many* columns, as Esne, Dendera, &c., and many inner chambers. 5. Those with large *courts*, and with *pyramidal towers* or propylons in front. The earliest temples were small, consisting of a simple chamber to hold the statue of the deity, with one opening or doorway in front, through which the votary might look, and with an altar for sacrifice. They were sanctuaries into which only priests might enter. The building was surrounded with a wall of brick forming a court or temenos, which was entered by a tall stone gateway or propylon, and was often planted with trees. In process of time these temples were enlarged, and there were added chambers for the priests, and large doorways flanked by towers with sloping sides (Plate VII. fig. 5), and sometimes by a portico or pronaos (fig. 2) supported by columns. The vestibule, or court-yard, was surrounded by a colonnade (fig. 4); the propylon was of gigantic proportions, and full of chambers (figs. 1, 4). The sanctuary, *adytum*, or σηκος (fig. 4), still contained the idol and its altar. Across the court, and, in fact, sometimes for an immense distance outside, there was a δρόμος, or avenue of sphinxes, through which processions defiled. At the commencement of this avenue there was frequently an open or hypæthral building, or peristyle of columns, where it is supposed the processions assembled and were marshalled. This building is called a canopy by Sir Gardner Wilkinson.

The pyramidal form of the propylæa, peculiar to Egyptian temples, may have been suggested by the pyramids, as neither that form nor those adjuncts to a temple appear to have been used before the period at which it is supposed the former were constructed. The grandeur and dignity inherent in that form would indeed hardly be suspected till its appearance in the pyramids themselves; and certainly the impression of its effect must have been strong, to induce men to seek it in a truncated pyramid under a very acute angle, as in the propylæa, relying on the effect of

its outline alone. It was gradually, too, that this tendency was generally applied, for in the earliest Pharaonic structures the vertical outline is most common, except in the propylæa, where they exist; and in the structures of the Ptolemies the inclined outline pervades everything. The larger and more perfect structures do not externally present the appearance of being columned, a boundary wall or peribolus girding the whole, and preventing the view of any part of the interior,—except perhaps the towering magnificence of some inner pylones; of the lofty tops of an extraordinary avenue of columns, with their superimposed terrace; of the tapering obelisks which occupy, at times, some of the courts; or of a dense mass of structure, which is the body of the temple itself, enclosing the thickly columned halls. The immense magnitude of these edifices may perhaps have made them, in their perfect state, independent of considerations which have weight in architectural composition at the present time, and on which indeed its harmony depends. The various portions of the same temple differ in size and proportion; whence it happens that the cornices of the lower parts abut indefinitely against the walls of the higher, while the latter are not at all in accordance among themselves.

Temple of Edfoo. Plate VII. The structure selected here to exemplify Egyptian architecture, and figured in elevation, plan, and details in Plate VII., though not ranked among the Pharaonic monuments, is perfectly characteristic of the style and arrangement of Egyptian temples, and is a more regular specimen than any other possessing the national peculiarities. It is known as the temple of Apollinopolis Magna, or of Edfoo, in Upper Egypt, on the banks of the Nile, between Thebes and the first cataract. It has recently been cleared out, and its magnificent ruins now stand forth grandly and clearly.

The plan of the enclosure behind the propylæa is a long parallelogram, the moles or propylæa themselves forming another across one of its ends. The grand entrance to the great court of the temple is by a doorway between the moles, to which there may have been folding gates, for the notches, as for their hinges, are still to be seen. Small chambers, right and left of the entrance, and in the core of the propylæa, were probably for the porters or guards of the temple: a staircase remains on each side, which leads to other chambers at different heights. To furnish these with light and air, loop-holes have been cut through the external walls, disfiguring the front of the structure. The grand doorway (fig. 4) is about 50 feet high, and is flanked by two massive towers 110 feet high. The whole facade measures about 250 feet, or about 70 feet longer than that of St Paul's. The propylon is covered with numerous figures, all of colossal proportions, and some as high as 40 feet. The court is 160 feet by 140, and is surrounded on three sides by columns 32 feet high, forming a covered gallery. The pronaos, or covered portico, measures 110 feet by 44, and consists of three rows of six columns, each 34 feet high, parallel and equidistant, except in the middle, where the intercolumniation is greater, because of the passage through. The front row of columns is closed by a sort of breastwork or dado, extending to nearly half their height, in which moreover they are half-imbedded; and in the central opening a peculiar doorway is formed, consisting of piers, with the lintel and cornice over them cut through, as exhibited in the elevation of the portico. From the pronaos another doorway leads to an atrium or inner vestibule, consisting of three rows of smaller columns, with four in each, distributed as those of the pronaos are. Beyond this vestibule there are sundry close rooms and cells, with passages and staircases which were probably used for storing the sacred utensils. The insulated chamber within the sixth door was most probably the adytum, or shrine of the deity or deities to whom the temple was dedicated. It measures only about 33 feet by 17 feet, while the whole edifice within the walls covers about as much ground as St Paul's, London.

The longitudinal section of the edifice (fig. 3) shows the relative heights of the various parts, and the mode of constructing the soffits or ceilings, which are of the same material as the walls and columnar ordinances; that is, in some cases granite, and in others freestone. The elevation of the pronaos (fig. 2) shows also a transverse section of the colonnades and peribolus. It displays most of the general features of Egyptian columnar architecture; the unbroken continuity of outline, the pyramidal tendency of the composition, and the boldness and breadth of every part. The good taste with which the interspaces of the columns are covered, may be remarked. Panels standing between the columns would have had a very ill effect, both internally and externally; and if a continued screen had been made, the effect would be still worse, as the columns must then have appeared from the outside absurdly short; but as it is, their height is perfectly obvious, and their form is rendered clear by the contrast of light and shade occasioned by the projection of the panels, which would not exist if they had been detailed between the columns. The lotus ornament at the foot of the panels is particularly simple and elegant; and nothing can be more graceful and effective than the cyma above their cornice, which is singularly enriched with ibis mummy-cases (figs. 6 and 7). The jambs forming a false doorway in the central interspace are a blemish in the composition; they injure it very much by the abruptness of their form, and their want of harmony with anything else in it. The front elevation of the moles or propylæa (fig. 1) with the grand entrance between them, is peculiarly Egyptian; and very little variety is discoverable between the earliest and latest specimens of this species of structure. It is an object that must be seen to be appreciated; simplicity and an inherent impressiveness in the pyramidal tendency are all on which it has to depend for effect, with the exception of its magnitude. The projecting fillet and coving which form a cornice to the structures, though large and bold, appear small and inefficient when compared with the bulk they crown; and there is nothing particularly striking in the torus which marks the lateral outline and separates the straight line of the front from the circular of the cornice. Neither are they dependent for their effect on the sculpture, for their appearance is as impressive at a distance, which makes the latter indistinct, as when they are seen near at hand.

A portion of the portico is given on a larger scale (fig. 5), to show more clearly the forms and arrangement of Egyptian columnar composition. The shaft of the column in this example is perfectly cylindrical. It rests on a square step, or continued stylobate, without the intervention of a plinth or base of any kind; and it has no regular vertical channelling or enrichment, such as fluting, but is marked horizontally with series of grooves, and inscribed with hieroglyphics. The capitals are of different sizes and forms in the same ordinance. In this example the capital, exclusive of its receding abacus, is about one diameter of the column in height. Its outline is that of the cyma, with a reversed ovolo fillet above, and its enrichment consists principally of lotus flowers. The capital of the column next to this (fig. 2), in the front line, is much taller, differently formed, and ornamented with palm leaves; the third is of the same size and outline as the first, but differently ornamented; and the corresponding columns on the other side of the centre have capitals corresponding with these, each to its fellow, in the arrangement. Above the capital there is a square block or receding abacus, which has the effect of a deepening of the entablature, instead of a covering of the columns, when the capitals spread, as in this case. In the earlier Egyptian examples, however, in which the columns are swollen, and diminished in two unequal lengths, the result is different, and the form and size of the abacus appear perfectly consistent. The height of this column and its capital, without the abacus, is six diameters. The entablature consists of an architrave and cornice, there being no equivalent for the frieze of a Greek entablature, unless the coving be so considered, in which case the cornice becomes a mere shelf. The architrave, including the torus, is about three-quarters of a diameter in height, which is half that of the whole entablature. The architrave itself is in this example sculptured in low relief, but otherwise plain. The torus, which returns and runs down the angles of the building, is gracefully banded, something like the manner in which the fasces are represented in Roman works. The coving is divided into compartments by vertical flutes, which have been thought to be the origin of triglyphs in a Doric frieze; but these are arranged without reference to the columns, and are in other respects so totally different from them as to give but little probability to the suggestion. The compartments are beautifully enriched with hieroglyphics, except in the centre, where a winged globe is sculptured, surmounting another on the architrave, as shown in the elevation of the pronaos. The crowning tablet or fillet is quite plain and unornamented. Angular roofs are unknown in ancient Egyptian buildings, and consequently pediments are unknown in its architecture.

Temple at Karnak. The temple at Edfoo, though its dimensions are considerable, is small when compared with that at Karnak. This covers about 420,000 feet, or five times as much as St Paul's, London, and more than twice as much as St Peter's at Rome. The propylon is 370 feet long, or twice as much as that of St Paul's. The hypostyle hall,[1] a parallelogram of about 342 feet long, and 170 feet wide, is the most wonderful apartment in the world. It has fourteen rows of columns, nine in each row, and 43 feet high; and two rows, six in each, of the enormous height of 62 ft., 11 ft. 6 in. in diameter, and carrying capitals which measure 22 feet across. This hall (with the two gigantic pylones) is said to cover 4000 superficial feet more than St Paul's. Beyond it is the adytum or shrine, a small apartment, measuring only 26 feet by 16 feet.

In many cases the temples want the peribolus and propylæa, the edifice consisting of no more than the pronaos and the parts beyond it. In others, particularly in those of Thebes, this arrangement is doubled, and there are two pairs of the colossal moles, and another open court or second vestibule intervening between them and the portico. The central line across the courts is formed by a covered avenue of columns, of much larger size than ordinary; and the galleries around are of double rows of columns instead of one row with the walls. The obelisks indicated in the plan and section of Edfoo (Plate VII.), before the propylæa, occupy the situation in which they are generally found, though in this case there are none. Colossal seated figures are sometimes found before the piers of the gateway; and from them, as a base, a long avenue of sphinxes is frequently found ranged like an alley or avenue of trees from a mansion to the park gate, straight or winding, as the case may require.

Statues. STATUES.—Connected with the temples, and forming an important part of their decorative features, were gigantic statues and obelisks. The statues are of enormous proportions. The sitting figure of Memnon is about 53 feet without the pedestal; and that in the sepulchre of Osymandyas (the Memnonium) is nearly 60 feet high. The face of Memnon is 7 feet high, and the ear 3 feet 6 inches long, and the shoulders measure nearly 26 feet across.

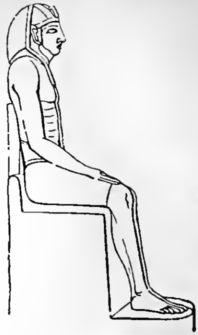

FIG 23.—Sitting Figure of Memnon.

Obelisks. OBELISKS.—The obelisks of Egypt are generally huge monoliths of red granite or syenite. Their use originated, no doubt, in the custom of setting up stones to commemorate particular events. The Egyptians embellished these stones, first, by working them to a fine face, and afterwards by covering them with carvings. They stand frequently in pairs before the propylon of the temples, as at Karnak and at Philæ. After the conquest of Egypt the emperors transported many of these monuments to Rome. At the time the celebrated *Regionaries* (accounts of each of the wards or *Regiones* of Rome) were written, there were six great obelisks, and forty-two small ones at Rome. Of these twelve only are now left, varying in height from over 100 feet to $8\frac{1}{2}$ feet. The first, which now stands close to the church of St John Lateran, is 148 Roman palms in height, or a little over 108 English feet, is about 8 feet square at the base, and weighs, as is estimated, nearly 450 tons. It is covered with hieroglyphics, from which we gather it was erected in honour of Thothmes IV. It stood originally before the temple of Amen Ra, and was brought over by Caligula. Each obelisk diminishes equally towards the top—that near the Lateran, ·253 part of the base; that at St Peter's, ·261; two at Thebes, ·3; and the one near S. Maria Maggiore, ·307, or nearly one-third. The diminution from the base may therefore be estimated roughly at from one-quarter to one-third.

The Barberini obelisk is about $7\frac{3}{4}$ times as high as the diameter of the base, Cleopatra's needle, $8\frac{1}{2}$; the one at St Peter's 9 times, at Luxor 10 times, at the Lateran 11 times; while two at Thebes, and one in the Piazza Navona at Rome, have an altitude of no less than 12 times the diameter of the base.

The obelisks have no entasis or swell from top to bottom like a column, but in almost all cases there is a slight convexity on the horizontal section of each face. The one in the Place de la Concorde at Paris has the peculiarity of being convex on one side, and slightly concave on another.

In all ancient examples, the small pyramid which covers the obelisk is at least $1\frac{1}{2}$ times as high as the diameter of the top of the obelisk in which it is placed. In modern examples the pyramidion is almost always too flat, which gives a bad effect. Obelisks appear to have been used in contrast with the long horizontal lines of the temples; so that we are unable to judge of the effect produced by these gigantic monoliths, when placed in their original positions, for the few examples in Rome, Paris, &c., are isolated and have nothing near them to contrast them with. The enormous labour and care expended upon the Egyptian obelisks may be judged from the fact, that the largest one at Karnak, which weighs 297 tons, must have been lifted out of the quarry, lowered into a ship, raised out of this into a carriage, transported more than a hundred miles on land, and

[1] So called by Diodorus Siculus, because the middle ranges of columns, with the roof, &c., are higher than the side parts, and admit light by a range of windows opening over the side roofs, something like the clerestories of our cathedrals.

then raised upright, and to a considerable height, to its pedestal.

Columns.

COLUMNS.—In the rock-cut tombs and temples we come to the earliest forms of columnar architecture now existing; and Sir Gardner Wilkinson considers that he can trace the process by which the plain, square, uncarved pier was gradually developed into the ornamental column of the complete Egyptian style. Thus in the case of a plain pier, the first thing was to cut off the angles, making it an octagon; a second cutting produced a 16-sided column. The sides slightly curved formed flutes, and a large slab on the top brought the whole to much the appearance of a rude Doric column.

Suppose, however, that the pier was painted on each side with the stem and bud or flower of a plant, *e.g.*, the lotus. The figure would be cut in intaglio; the plain spaces between being then cut away, the column would represent 4 or 8 stalks, supporting buds in flower conjoined. These would be united together by sculptured bands, and the whole would form one column of 4 or 8 stalks, supporting a capital.

Sir G. Wilkinson has classed Egyptian columns into eight orders. *First*, The *square pillar*, or post of stone. This often has a line of hieroglyphics running down it vertically. *Second*, The *polygonal* column, plain or fluted. This is sometimes painted, or otherwise ornamented with devices. *Third*, The *bud* capital, or one formed like the bud of the papyrus. Of this there are three varieties. The oldest, from Beni Hassan, is composed of four plants bound together by a sort of necking of fine bands under the buds, the columns coming down straight to the plinth. Then there are columns of eight similar shafts, and these generally turn in at the bottom. After the reign of Amenoph III. simple round shafts came into use. The second variety is composed of similar shafts, capitals, and neckings; but there are similar bands or necking on the bud itself, and a sort of short rods or reeds, descending vertically from the neckings on the sides of the column. The third variety has a single circular shaft, without any indication of the united water plants, but still with bands round the necking, and the capital itself. In these two last varieties the lower part of the shaft is generally ornamented with a sort of sheath or spathe, resembling the lower part of a water plant.

In the *fourth* order the capital is like an *inverted bell.* It formerly was called the lotus capital, but in reality it has no resemblance to that flower. The capital is so much undercut that the ornaments on its edge are not visible, except to a spectator who is immediately beneath them.

The *fifth* order is the *palm tree* column, and resembles the head of that tree, with the lower or drooping boughs cut off. The neckings are composed of five bands, but have the peculiarity of a piece hanging down like a knot at the end. These columns are found as early as the time of Amenoph III. In the time of the Ptolemies the shafts came straight down to the plinths, and were not drawn in at the bottom as in the earlier periods.

The *sixth* order is called the *Isis-headed order*, the capital being formed of one or more heads of that deity, surrounded by a representation of a doorway, or small shrine with an image, and sometimes a votary worshipping placed over it. At Dendera the faces, exclusive of the head-dress, are five feet across. Sometimes the Isis head is formed on a square or polygonal column. Sometimes the head is that of Athor, the Venus of the Egyptians. In this order also are included the capitals at the tomb of Rhamses III. at Thebes. These are the heads of cows painted blue and red, and with long reverted horns.

The *seventh* is called the *composite order*. The shafts are generally round, and the capitals, as the name imports, are a mixture of styles. The bell and palms, or the palm and the Isis head, are frequently found in combination. A most curious instance is ranked under this style, of columns of the third order with inverted shafts, and also inverted capitals, taken from Karnak, the work of Thothmes III.

The *eighth* order is called the *Osiride*, from containing statues of the deity Osiris. This order is something like the Persian, or the Caryatides of the Greeks and Romans; but it differs, inasmuch as the figure does not support the entablature, but stands in front of a square pier which discharges that duty. This order is sometimes used in the courts and sometimes in the halls. Grotesque figures of Typhon are found in a building called the Typhonium at Barkal. These, however, partly support the entablature with their odd-shaped caps.

The following list of heights, diameters, and distances between the columns, selected from those given by Canina and Sir G. Wilkinson, shows at one view the peculiarities of the various styles:—

	Height.		Diameter.		Inter-columniation.	
	ft.	in.	ft.	in.	ft.	in.
Beni Hassan, square, ...	18	4	3	8	6	1
Do., polygonal, ...	16	8	3	7½	10	5
Do., four reeds, ...	15		2	4	7	2
Karnak, bud capital, ..	18	11	3	8	6	6
Do., side colonnades, do.,	39		9	6	9	4
Do., central, fourth order,	60	3	11	8	12	6
Memnonium, do., do., ...	29	4	7	2	7	2
Do., side do., do., ..	22	10	5	8½	8	7
Dendera, sixth order, ...	43	2	8		8	5
Esne, seventh order, ...	29	11	5	9	8	
Edfoo, do., ...	43	2	8		8	5

PILASTERS.—These are employed in all ages, though they do not always accord with the order of the columns. For instance, at Thebes the pilasters of the Temple *in antis* of Dayr el Medeeneh are of the sixth or Isis-headed order, while the columns between are of the seventh or composite order. They are generally square, and without diminution.

Pilasters.

ENTABLATURES.—These are nearly alike in all orders, and may be described as a cornice and architrave without a frieze. The former consists of a fillet or regula, beneath which is what is generally called a large hollow or cavetto; but in reality the upper half is a quarter round, and the lower nearly straight. Under this moulding is a bold torus which separates the cornice from the architraves, and runs down the sloping sides of the angle of the building to the ground. The cornice is generally ornamented with divisional vertical lines, like triglyphs. Between these the cartouches or ovals of the reigning monarch, or other devices, are carved. The centre is generally occupied by the winged globe, or emblem of the Good Dæmon. The torus is often ornamented as if strings were bound round a bundle of sticks, like the *fasces* of a Roman lictor. On the upper part of the smaller cornices there is often a row like the antefixæ of a Greek temple, but their form is peculiar, and is supposed to represent the pots in which the mummies of the sacred cats and ibis were preserved. The architraves are plain, without being broken into fasciæ, and are generally covered with hieroglyphics.

Entablatures.

FORTIFICATIONS.—Next to the temples, the grandest buildings were perhaps the fortifications. We know that the temples themselves were often used as citadels, few of the towns being fortified. Even Thebes seems not to have been so. Of the actual citadels we have a few remains, as at Dakkeh. But several are shown on the drawings, and bear a curious resemblance to mediæval works, the ramparts of the walls and towers having battle-

Fortifications.

ments which overhang like our machicolations, while, in the centre of the enclosure formed by the walls, was generally a high square tower or keep. Of the further details we know little.

Private Dwellings. PRIVATE DWELLINGS.—Of these little is known, except from paintings found in the tombs. One noted ruin at Medinet Haboo has, indeed, been supposed to be that of a palace; but one of the latest authorities, M. Mariette, throws doubt on this, considering that it was erected partly for defence and partly as a triumphal monument. The ordinary dwellings seem, like the houses in the Labyrinth, to have been in two stories, with an open gallery at the top, supported by columns probably of wood. The larger houses consisted of rooms ranged round three sides, and sometimes four, of a large court-yard planted with trees, and with a tank, and perhaps a fountain, in the middle. There was an entrance porch, on which are hieroglyphics, being, as Sir G. Wilkinson supposes, the name of the inhabitant. Larger houses are supposed to have had two courts—the outer, in which to receive vistors, the inner for the females of the family. Smaller houses, particularly in the country, had a similar court, with granaries and store-rooms below, and living apartments above, like those of the modern Fellah in Egypt, or the small *vigna* houses in Italy. The roofs seem to have been flat, like those of the modern Egyptians; and the houses appear, from a painting found at Thebes, to have been ventilated in the same way as at present, by the contrivance called a *mulkuf*, or wind-shaft, over which are two screens, like large square fans back to back, bending forward each way to catch any air that may chance to be stirring, and direct it down the shaft into the house.

Résumé. Although we have only ruins to guide us (for no man living has seen an Egyptian temple as it appeared to the old Egyptians), yet we can gather that to the Egyptians we owe the earliest examples of columnar architecture, and at the same time that they had not got beyond the rudiments of it. The stable effect of their massive columns disappears when we notice that scarcely any, except those of very recent date, have the wide-spreading base which we know so well in every other style; that the massiveness of the column is in fact wasted, as the lower part is rounded off and cut away so as to render $\frac{1}{4}$th of it simply useless; and that the bold projecting capital carries no weight, and adds nothing to the strength of the stone beam above it, for that beam rests on a small block of stone *above* the capital, borrowing no strength whatever from it. It will also have been noticed, that nearly every Egyptian work is rectangular in plan, and that in exceptional cases, as, *e.g.*, the buildings at Philæ, Kalabsche, and Luxor, no attempt has been made to soften down the harshness of the lines. With the elevation it was the same. The square was never changed into the circle or the octagon. Nearly every form is bounded by the rectangle, and the only varieties found in the grandest of the buildings in Egypt are the slope of the massive pylon and the tapering obelisk. The minaret and the dome, which give such charming variety of outline, and the varied mouldings, without which it now seems to us that no building could be perfect, were unknown to the Egyptians.[1] But of all things, the neglect of the arch is the most curious. Crude brick arches are found at least as early as the 16th century B.C., and others have been found of the same date, it is thought, as the pyramids. Yet the Egyptians of later times systematically employed enormous stones for their coverings and lintels, and left the arch unused. We must remember, in justice to the Egyptians, that their efforts in art were fettered, to an extent which we are perhaps unable to appreciate, by the restrictions imposed upon them by conventionalities connected with their religion. That they were so fettered in sculpture at least is abundantly clear from many examples. The freedom which characterises one of their earliest statues, that of King Chephren, the exquisitely bold yet delicately graceful sculptures in the Serapeum and in the tomb of Tih at Sakkara, and other examples, show clearly that the Egyptians had a power for design and execution which only such a cause as that referred to above could have suppressed.

[1] One example, apparently, of a cupola occurs in a painting at Bayr el Bahree (Thebes), but no trace of an actually built cupola exists.

JEWISH ARCHITECTURE.

The long sojourn of the Jews in Egypt, and the fact that their chief employment there seems to have been the manufacture of bricks, must have made them acquainted with the architecture of that country. On the conquest of Canaan, the Israelites seem to have taken possession of the dwellings of the vanquished people; and we have no record of any important building constructed by the Jews till the days of Solomon. The piety of this prince seems to have induced him to carry out his father's wishes with regard to the temple, but at so low an ebb was the art of building that the Jews did not even know how to hew timber properly (1 Kings v. 6). The king therefore applied to Hiram, king of Tyre, with whom he was on friendly terms, and that monarch sent an architect and staff of skilled workmen. Materials were collected for the building, and careful accounts of the whole work are given in the books of Kings and of Chronicles. Solomon's temple.

The early temple is described (1 Kings vi. vii.) as a building of stone, roofed and floored with cedar. It appears to have been rectangular, with a single roof, and divided into two parts by a wall. It was 60 cubits[2] long, 20 wide, and 30 in height, or about 110 feet by 36 feet, and 55 feet high. In front was a porch the same width as the temple (20 cubits), but only 10 cubits in depth.

Round the house—which, of course, must mean on three sides only, as the porch occupied the front—were the priests' chambers, in three stories, one over the other, the lowest 5 cubits broad, the middle 6, and the upper 7,—a passage which has puzzled most commentators, but which will be considered presently. On the right side was a winding-stair leading to the upper stories of chambers. The walls of the house, as well as the ceiling, were lined with boards of cedar. The joists of the floor seem also to have been of cedar; but the floor itself was of planks of fir. The cedar was carved with "knops" and open flowers.

The house was, as has been said above, divided crossways into two parts—the outer temple and the oracle, or Holy of Holies. The one was 40 cubits long, by 20 broad; the other was 20 cubits square. The oracle had doors and door-posts of olive-wood. The temple door-frames were of olive, and the doors of fir, all being hung folding. Both doors were carved with cherubim, palm trees, and open flowers. The entire fabric, even the floors, were gilt —"overlaid with gold." The account in the Second Book of Chronicles (ch. iii. iv. &c.) is substantially the same, except (a difference easily to be accounted for) that it describes the greater house, *i.e.*, the outer temple, as ceiled with fir tree; and we gather also from the description, that the whole was roofed with tiles of gold: the nails were also of gold, and weighed 50 shekels. At the door of the porch were two columns of bronze, or "pillars of brass," each 18

[2] Canina makes the sacred cubit = ·554 of a French metre, *i.e.*, 21·81 English inches, or not quite 1 foot 10 inches.

cubits, or 33 feet high, and 12 cubits round, or about 7 feet in diameter. They had capitals (chapiters) also of molten brass, five cubits high, decorated with lily work, chain work, and pomegranates. In front of the porch was the altar, surmounted by a low wall three courses of stones in height. The whole building was enclosed by a walled court, called the inner court, or that of the priests. In front of this was another, called the lower court; and the whole of this area was enclosed by a circumscribed court going round the whole of the other courts and buildings; and this was called the outer court, or that of the Gentiles. It will be noted that in the careful description of the pillars, &c., no mention is made either of base or of moulded cornice.

Canina (*Tempio di Gerusalemme*, Rome, fo.) conceives the style of the building to have been Egyptian; that the temple was lighted like the hypostyle halls, by a range of windows over the roofs of the cells or priests' chambers; that these windows were like those of the clerestory of a church splayed at the bottom and sides; that the walls of the temple itself sloped towards the top on the outside, or, to use the technical language, were built "battering," while the walls of the priests' chambers were built perpendicular, and for this reason each story measured a cubit more than the room below. He also supposed that the capitals of the columns, which are described as of lily work, were in fact the lotus (water lily) capital of Egypt. The porch itself he considers to have been like the propylon, containing other chambers like those of Egypt.

Mr Fergusson's restoration, as given both in his *History of Architecture* and more at length in Smith's *Dictionary of the Bible*, is different. He assumes that the plan was somewhat analogous to that of the still existing building known as the palace or temple of Darius at Persepolis, which has a range of chambers on each side. The difficulty as to the upper chamber being wider than the lower he solves in a very satisfactory way, by supposing that there was a set-off in each story on which the flooring just rested, so as not to cut into the walls of temple.

In the prophecy of Ezekiel (ch. xl. *sqq.*) we have a very full and interesting account of what the temple was in his time. The house itself and the oracle do not appear to have been altered, but the old courts seem to have been swept away and succeeded by vast atria, and a mass of halls and chambers.

Temple of Herod.

In the time of Cyrus the temple was rebuilt, but this second temple was demolished by Herod, who constructed a new one of the same dimensions as that of Solomon. The outer house was 40 cubits long, and the Holy of Holies 20 cubits; but it was nearly double the height of the first temple. The porch also, instead of being the width of the house, 20 cubits, was 100 cubits long and 100 high, crossing the temple in the form of a T, and forming a magnificent façade much longer than that of St Paul's in London. Round the house were three stories of priests' chambers. The court had three entrances on each side, which were called respectively the water-gates, the fire-gates, and the oblation-gates. But the peculiar difference between Herod's temple and the earlier building was that there was, in front of the court last described, another of about the same size, surrounded by a colonnade and chambers, which was the place set apart for the women. These courts were surrounded by an outer court, having a species of cloister on the north, east, and west sides, composed of a double row of columns. On the south side was a similar construction a furlong in length. It consisted of three rows of columns, forming with the outer wall, three aisles—the two outer being 30 feet wide and 50 feet high; the centre being 45 feet wide and 100 feet high—no doubt with a species of clerestory. These columns are described to have been so large that it took three men with extended arms to span their circumference. The outer court was elevated six steps above the basement level; the inner courts stood on a sort of plateau, with retaining walls and parapets round it, which was ascended by fourteen steps; this was on the level of the women's court. Between this and the inner court was a gate called that of Nicanor, in front of which was a semicircular flight of fifteen steps. The temple itself was entered by a flight of twelve steps, so that its floor must have been between 20 and 30 feet above the ground-level of the surrounding city. The whole was built of the most beautiful white marble.

House of the forest of Lebanon.

We read in the First Book of Kings (vii. 2, 8), that Solomon built "the house of the forest of Lebanon," "his house where he dwelt," and "a house for Pharaoh's daughter." Some have supposed these to have been three distinct palaces, but Canina considers them as all connected, and as three parts of one large structure. The house of the forest of Lebanon—so called, in all probability, from the cedar of which it was constructed—is described as being 100 cubits long, 50 wide, and 30 high (180 feet by 90 by 54). Its horizontal area was thus very nearly equal to that of Westminster Hall. It had four rows of cedar pillars, or, as the Vulgate more correctly renders it, four corridors (*deambulacra*) formed by three rows of cedar columns, fifteen in each, or forty-five in all, with cedar architraves, and covered with cedar. This Canina restores as an Egyptian hall, lighted, as described by Vitruvius, with a portico in front, of 50 cubits by 30. The great hall, he supposes, led on one side to the palace occupied by the king, in which was the hall of judgment and the throne, and on the other side, to the queen's palace and the women's apartments, or, as it has been called in later times, the harem. The porticoes and hall seem to have been of cedar, but the houses were "of costly stones" (1 Kings vii. 9).

The excavations recently made, at the expense of the Palestine Exploration Fund, have disclosed considerable remains of the massive ancient masonry, and of the cisterns, conduits, &c. But, with these exceptions, no part of old Jerusalem appears to be extant. There are, however, some objects, formerly considered to belong to Jewish times, that should be mentioned. There are, first, what are called the tombs of the kings of Judah. These are a number of sepulchral chambers hewn out of the solid rock, and containing sarcophagi. They vary from 10 to 20 feet square, and are entered, exactly like the tombs of Beni Hassan, by a portico *in antis*, about 40 feet wide. There are two columns and two pilasters in front, of Greek Doric character, about 13 feet high. The most curious feature of these is, that a broad band, about 3 feet wide, richly sculptured with foliages, runs down on each side 4 or 5 feet and over the columns horizontally. Above this last, quite independent of the lower construction is a regular Doric architrave and frieze, of a character between Grecian and Roman; this is ornamented with triglyphs, pateræ, and foliage. In front of the portico is a large court-yard, about 100 feet square.

Tombs of the Kings

In the Valley of Jehoshaphat, near Jerusalem, are three extremely curious relics; two stand alone, on platforms excavated from the rock, and the third is scarped into the rock itself. The first is called the tomb of Absalom. It is a square building with a solid wall, in which are engaged Ionic columns, about 13 feet high; over this is a Doric entablature with triglyphs, and an altar, surmounted by a very curious sort of hollow-sided cupola of trumpet-mouth section, and a terminal. The whole, including the flight of steps, is about 60 feet high.

Another similar building, of about the same size, is commonly called the tomb of the prophet Zechariah. This is surmounted by a simple pyramidal roof. Beneath it is a handsome doorway leading to a sepulchral chamber. Over the ordinary classic entablature is the regular Egyptian cornice or torus, surmounted by a bold quarter hollow and fillet exactly like those on the propylons of Egypt, which have been already described.

The third building is entirely rock-cut, and consists of a large façade, about 90 feet wide and 100 feet high. This is reported to be the place to which the apostles retired before the siege of Jerusalem. Below is a plain face, about 45 feet high, on each side of which are wings with two pilasters, both running up to the top of the building. Between these is a species of portico, about 40 feet wide, with columns and pilasters, of nearly pure Grecian Doric. There are also several other rock-cut tombs or sepulchres scattered about in the neighbourhood of Jerusalem, but none of them possess much architectural interest. One is called the sepulchre of Jehoshaphat.

From the character of the architecture it is incredible that these buildings can have anything like the age ascribed to them. The Ionic capitals are evidently Roman, and therefore cannot date earlier than the conquests by that people; probably they are of the time of Herod; while the Egyptian cornices show that the traditional ornaments of that people had not been entirely forgotten. Besides this, the general plan of a temple, *in antis*, scarped into a rock, so entirely resembles the work at Beni Hassan, that it is impossible to deny that these very interesting remains strongly corroborate the views of Canina, that the architecture of the early temples was at least based on the architecture of the Egyptians.

Indian Architecture.

Considerable light has been recently thrown upon the history of architecture in the East. The traditions as to the extremely remote antiquity of the rock-cut temples, the caves of Ellora, and the wonderful pagodas, have disappeared before the searching eye of critical investigation. In the time of Herodotus the Persians had no temples; and even in that of Tacitus, the great Indo-Germanic races "would not confine their gods within walls." The early religion, which appears in the Vedas, was Brahminism, but in the 6th century B.C., the first of the Buddhas seems to have commenced a perversion of the ancient faith. The struggle appears to have gone on for years, till three-quarters of a century after the time of Alexander the Great, about 250 years before the Christian era, when a powerful ruler named Asoka, a grandson of Chandragupta, who is supposed to be the Sandracottus of the Greek writers, abjured Brahminism, and made Buddhism the religion of the state. Certain *Lats*, or pillars, erected by him, and inscribed with his edicts, are the earliest extant architectural remains of India.

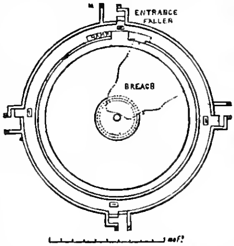

Fig. 24.—Plan of Tope at Sanchi.[1]

Topes. The Buddhist topes are supposed to have been erected at first to commemorate some event, or to show that the spot was sacred; but after a time they were employed to contain relics, such as the tooth or collar-bone of one of the Buddhas. The relics seem in some cases to have been preserved in a sort of box or case at the top of the tope, called a *tee;* in others, in regular relic chambers. Where there were relics, the place was called *dagoba*, or relic shrine, of which, perhaps, our term pagoda is a corruption. A great number of these topes were built in the form of large towers, others in the form of hemispheres. One of these, the Sanchi tope, is described and figured by Mr Fergusson. The diameter is 106 feet. It has a curious species of gate entrance, and is surrounded by a stone fence. Others are partly cylindrical, and are finished with either a flat circle, or pointed terminals like a dome at the top. A fine example has recently been discovered at Bharhut by General Cunningham.

Of the next two classes of Buddhist architecture, the temples (Chaityas) and monasteries (Viharas), no *built* examples exist in India. They are, in fact, rock-cut caves. At least one thousand temples are known—one-tenth probably Brahminical or Jain, the rest Buddhist. They are Rock-cut temples.

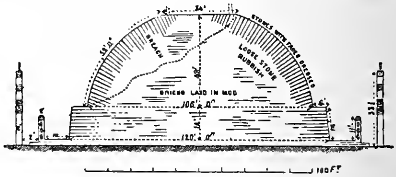

Fig. 25.—Section of Tope at Sanchi.

said to form an uninterrupted series, from the first, in Behar, by the grandson of Asoka, 200 years before Christ, to those at Ellora, which, instead of being of an almost diluvian antiquity, as has generally been reported, have been proved to date from the 7th or 8th century of our era, while the most recent is the work of Indra-dyumna, as late as the 12th century. One of these cave-temples at Karli,

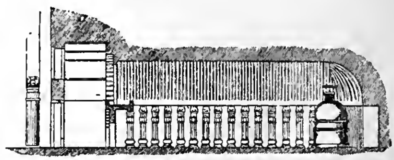

Fig. 26.—Cave at Karli: section.

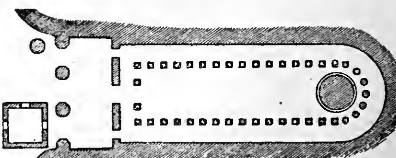

Fig. 27.—Cave at Karli; plan.

near Bombay, presents exactly the features of a Roman basilica, or early Christian church. It has a circular end or apse, and is divided into three aisles by two rows of columns. Others are simple square buildings, with a circular or oval chamber at the end entered by a small door. The monasteries, which exceed the temples in number, seem generally to have been square caves supported

[1] Figs. 24 to 38 are taken from Fergusson's *History of Architecture*, by the kind permission of the author.

by pillars of the natural rock left in their places, and surrounded by a number of small sleeping-places or cells.

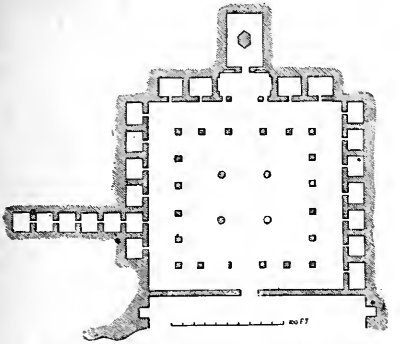

FIG. 28.—Cave at Baugh, on the Nerbudda ; plan.

Ellora caves. The most wonderful excavations are those at Ellora, near Aurangabad. These are a series of hypogea or caves sunk in the solid rock, extending a distance of 3 or 4 miles. Canina has given plans and interior views of six of them. Those called Parasova Rama and Diajannata are simply halls supported on massive piers with level architraves. The piers are richly carved with figures and friezes, and have a sort of cushion capitals, and square abaci, and stand round, forming a kind of atrium. That called Indra has a court open to the sky, in which is a small shrine or temple. In the solid rock are two halls similar to those above described, a larger and smaller. The piers of the Tin Tal are quite plain. In the Viswakarma is a quadrangle, open to the sky and surrounded by pillars. This leads into an atrium with three aisles and an apse, and exactly like a basilican church.

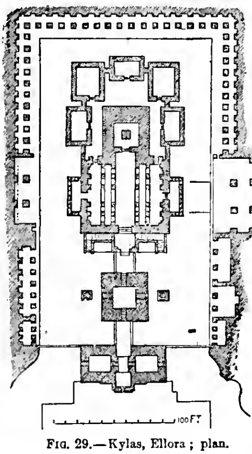

FIG. 29.—Kylas, Ellora ; plan.

Kylas. The most magnificent of the Ellora caves, and indeed of the native Hindu works, are the chambers and halls called the Kylas, or Kailasa. These are sunk into the rock, and occupy a space of 270 feet deep and 150 feet wide. The roofs are solid rock, supported by pillars, or rest on the walls, or on the divisions of the assemblage of chambers. There is a porch, on each side of which are two columns. This conducts into a hall, supported on 16 such columns, and leading into a sort of adytum. Round this is passage space and five chambers. The whole forms a temple, with its usual appendages, just such a one as would be built on the ground, and round this a wide open space, with a colonnade or cloister encircling the whole. Great part is open to the sky, for the sake of light and air, but the work is entirely cut out of the solid rock.

FIG. 30.—Kylas, Ellora.

The date of the construction of the Kylas is about 1000 A.D.

Jain work. The earliest existing work of the Jains seems to be of the 10th century. They were a sect which arose in the endeavour to re-establish Brahminism, and which first seems to have acquired importance about 450 A.D. This sect rejects the doctrines of Buddhism, as also the practice of monasticism. The famous temple at Somnauth belongs to them. Mr Fergusson has given a description of that built by Vimala Sah, on Mount Abu, as a type of the ordinary Jain temple. In the centre is a cell in which is a cross-legged figure of one of the twenty-four saints worshipped by this sect; in this case it is that of Parswanath. The cell is always terminated by a pyramidal roof. In front of this is a portico of 48 pillars, disposed much like a cruciform church with a dome at the intersection of the transepts. The whole is surrounded by a species of cloister formed by double rows of columns, and a series of small chambers like the cells of a *vihara*. But as the sect abjure monasticism, each cell is used not as a dwelling, but as a kind of small chapel, and contains one of their cross-legged deities. One of the peculiarities of this style is that richly-carved brackets spring from the pillars at about two-thirds of their height, and extend to the architraves, forming a sort of diagonal strut to strengthen and support them.

The Jains probably adopted the dome at a very early period, and it is doubtful whether the Buddhists ever used this species of construction. "No tope," Mr Fergusson observes, "has the smallest trace of such a structure, though of domical shape outside, and the design of the rock-cut temples, with the upright supports, the raking struts, and the level architraves, has manifestly been deduced from timber construction." The Indian dome has no voussoirs radiating from the centre, as in European architecture. The courses are all horizontal; and the domes are therefore necessarily pointed in section, for they would not stand if circular. The Indian dome, however, has this merit, it requires no abutments, and has no lateral thrust. The pressure is entirely vertical; and if the foundation be sound, and the pillars stout enough, there can be no failure.

The leading idea of the plan of the Jain temple is that of a number of columns arranged in squares. Wherever it was intended to have a dome, pillars were omitted, so as to leave spaces in the form of octagons. By corbelling over the pendentives in level courses the dome was gradually formed. The plan and view of the temple at Sadree exhibit a building as large as most cathedrals. It has the great number of 20 domes, varying from 36 feet to 24 feet in diameter, and supported by 420 columns.

Like most architectural peoples, the Jains were also fond of tower-building. The *Jaya Sthamba*, a tower of victory erected by Khumbo Rana, to commemorate the defeat of Mohammed of Malwa, in 1439, is nine stories high, the two topmost stories being open. The general outline is not unlike that of an Italian campanile, with pilasters at the angles, and an overhanging corbelled top. It is richly ornamented from bottom to apex, and affords a very favourable idea of Indian art.

Hindu architecture has been divided into that of the Aryan or Sanscrit races of North India, that of the South or of the Tamul races, and that prevalent in the Panjab and Cashmere. Of the first and last we have comparatively little knowledge, but South Hindu work is treated of at great length by Rám Ráz,[1] a native author. The accompanying view of the temple at Tiravalur (fig. 31), which measures 945 by 700 feet, is from his work on Hindu Architecture. The remains of the buildings are numerous, as the Tamul races were perhaps the greatest temple builders in the world; and the whole subject has been so well elucidated by the author last referred to, that its principles may be considered to be clearly ascertained and settled. The great pagoda at Tanjore (fig. 32), by far the grandest temple in India, resting on a base 83 feet square, rises in fourteen stories to a height of nearly 200 feet. The interior represented in fig. 33—a hall in the palace at Madura—illustrates a comparatively recent style.

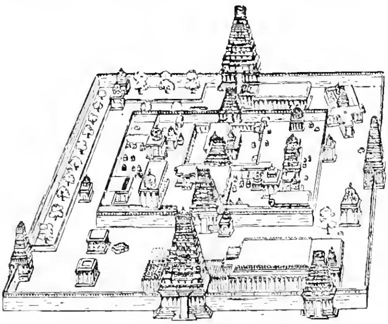

FIG. 31.—Temple at Tiravalur, near Tanjore.

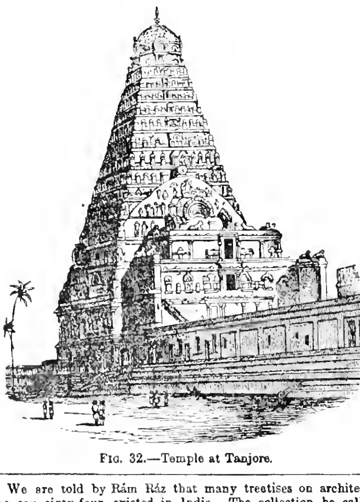

FIG. 32.—Temple at Tanjore.

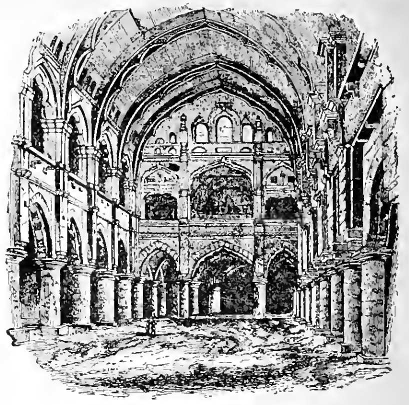

FIG. 33.—Hall in Palace, Madura.

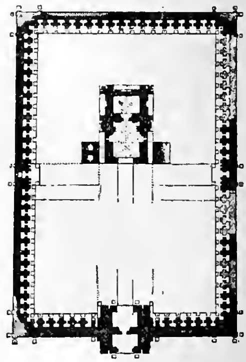

FIG. 34.—Temple of Martund; plan.

The architecture of the north-east is known chiefly from the drawings in Vigne's *Travels in Cashmere*, and in General Cunningham's *Memoir to the Asiatic Society of Bengal*. The temple of Martund (fig. 34), reduced from the latter work by Mr Fergusson, shows a cloistered court surrounded by pillars and cells, and entered by a porch. In the middle of this is a temple with a species of *naos* and *pronaos*. But the most curious feature is a series of doors with acute pediments over them shaped very much like Gothic gablets, and containing trefoil arches. A similar feature occurs (fig. 35) at Pandrethan, in a temple built about 1000 A.D., or 250 years later than Martund. It seems by no means improbable that these pointed domes,

[1] We are told by Rám Ráz that many treatises on architecture, some say sixty-four, existed in India. The collection he calls the *Silpa Sástra* Of these he mentions that the most perfect is the *Mánasára*, of which forty-one chapters were in his possession He also cites several others, one of which he calls *Casyápa*. In an epitome of the *Mánasára* he states that the first chapter treats of the various measures in use in the country; the second describes the *sthapati*, or architect—the *sútragráhi*, or measurer, probably the surveyor or clerk of works, and then the various builders; while others treat of pillars, bases and pedestals, halls, and the Vimana or temple itself.

gablets, and trefoiled arches may have strongly affected the architecture of the Saracens.

Of the style of North India Mr Fergusson gives remarkable, and by no means elegant, examples; as the Black Pagoda at Kannaruc, and temples at Barolli and at Benares. The chief features are a sort of entrance porch, sometimes walled and sometimes carried on pillars, called the nuptial hall, leading into a great pagoda, square in plan, and finishing with a sort of tub-shaped dome. The ornamentation is profuse, so much so as to detract from the greatness of the design. There are no buildings in this style anterior to the Mahometan conquest The date assigned to the temple of Jugernath is 1198, and to the Black Pagoda, 1241 A.D. The ghâts, or landing-places (fig. 36), that line the banks of the rivers of Northern India, are often of great architectural merit.

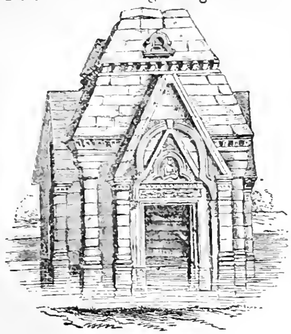

FIG. 35.—Temple at Pandrethan.

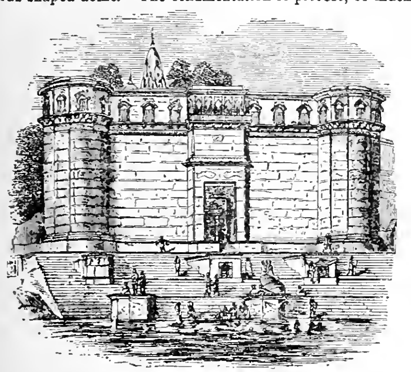

FIG. 36.—Ghoosla Ghât, Benares.

FIG. 37.—Shoemadoo Pagoda, Pegu.

The pagoda forms a very prominent feature in the architecture of Further India. A specimen of the Burmese style of temples is presented in the Shoëmadoo (*i.e.*, "golden great god") Pagoda of Pegu (figs. 37, 38).

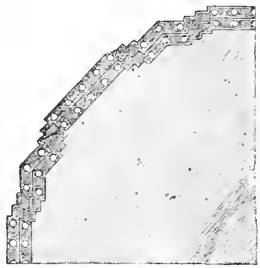

FIG. 38.—Shoemadoo Pagoda, Pegu; quarter of plan.

ASSYRIAN ARCHITECTURE.

Assyria and Babylonia or Chaldea may be shortly defined as the countries watered by the Euphrates and Tigris, lying between Armenia and the Arabian desert, and reaching down to the Persian Gulf.

The capital, Ninus or Nineveh, was taken by the Medes under Cyaxares, and some 200 years after Xenophon passed over its site, then mere mounds of earth. It remained buried until 1845, when Botta and Layard discovered the ruins of the Assyrian cities. The principal remains are those of Khorsabad, 10 miles N.E. of Mosul; of Nimroud, supposed to be the ancient Calah; and of Kouyunjik, in all probability the ancient Nineveh. In these cities are found fragments of several great buildings which seem to have been palace-temples. They were constructed chiefly of sun-dried bricks, and all that remains of them is the lower part of the walls, decorated with sculpture and paintings, portions of the pavements, a few indications of the elevation, and some interesting works connected with the drainage, &c.

The structures were built usually on artificial mounds, and approached, it is supposed, by great flights of steps (of which remains composed of black basalt have been found at Khorsabad). They consist of series of halls and chambers of no great size, the largest hall in Sennacherib's palace at Kouyunjik being only 200 feet by 45 feet, whereas Westminster Hall is 268 feet by 68 feet. In their proportions they are utterly unlike Egyptian structures, and they display the striking peculiarity of being elongated beyond anything known in other styles of architecture; *e.g.*, one of the Kouyunjik halls is 122 feet long by 27 wide, another is 218 feet long by 25 wide. The great hall at Nimroud, though 162 feet by 62, was divided lengthwise in the centre by a wall 12 feet thick, leaving each side only 25 feet wide. Another peculiarity of these structures is the immense thickness of the walls. Those of the Kouyunjik hall (27 feet wide) were 15 feet thick, and those of Nimroud (32 feet wide) were 26 feet thick. It has, indeed, been reckoned by Mr Fergusson, that in some of the palaces the area of the walls is as great as that of the chambers. The reason he suggests for this is that these thick walls supported a double row of columns as a clerestory under the roof, so arranged as to give light and air, while excluding the rays of the sun. He covers the halls with flat roofs, supported on columns, which being of wood have rotted or been burnt. An entirely different theory is that of M. Flandin, who studied the subject on the spot. He believes that the halls were vaulted and had small windows at the springing. M. Victor Place has found at Khorsabad several vaults, and also terra cotta tubes, through which he believes that the vaults were lighted, just as domes were in Persia in later times. But no vault has been found large enough to span any of the wide Assyrian halls. Of their elevations there are few traces remaining. At Nimroud, what is supposed to be the tomb of Sardanapalus has its lower part, which is about 20 feet high, of solid masonry, and the rest of burnt bricks. It has slightly projecting piers, but no ornaments or mouldings. At Khorsabad and the S.E. palace of Nimroud there is some attempt at decoration, by rude semi-columns, without capitals or bases, arranged in clusters of seven, side by side, the groups being separated by recesses. A few detached pieces of moulding have been found at Khorsabad, but of the very simplest kind, and we have no vestiges of capital or entablature. Were our knowledge limited to these and a few similar remains, we should have to form but a poor idea of Assyrian art. But the sculptures have revealed to us a degree of refinement which had been previously looked for only in Greece. These sculptures lined the sides of the halls to a height of 10 feet. In them we see columns with both base and capital, and surmounted by entablatures. Sometimes the columns are combined with pilasters, as in the Greek porticos *in antis*. In one specimen the columns were carried on the backs of bulls, as is shown by one of the bas-reliefs, and, more conclusively still, by the beautiful small model of a winged bull brought to England by Mr George Smith, which has carved upon its back a base, just as is shown on the slabs.

In these bas-reliefs we have further—1. The facade of a palace, having at top a grand row of window openings divided by Ionic columns; 2. A small building on the banks of a river, having two columns with bases and a kind of Ionic capital, between two plain pilasters, and with rude indications of a cornise; 3. Another façade of two columns, with bases, and Corinthian capitals, between two pilasters, likewise with capitals. Over these is an entablature, somewhat rudely worked, but clearly showing architrave, frieze, and cornice, and antefixæ over. The latest of these slabs must have been carved many years before the earliest date assigned to any known Greek work. In view of these and similar remains the following words of Niebuhr are memorable:—"There is a want in Grecian art which no man living can supply. There is not enough in Egypt to account for the peculiar art and mythology of Greece. But those who live after me will see on the banks of the Tigris and Euphrates the origin of Grecian mythology and art."

The plans of all the Assyrian buildings are rectangular, and we know that long ago, as now, the Eastern architects used this outline almost invariably, and upon it reared some of the most lovely and varied forms ever devised. They gather over the angles by graceful curves, and on the basis of an ordinary square hall carry up a minaret or a dome, an octagon or a circle. That this was sometimes done in Assyria is shown by the sculptures. Slabs from Kouyunjik show domes of varied form, and tower-like structures, each rising from a square base. The resemblance between the ancient form of the dome and those still used in the Assyrian villages is very striking. Whether sloping roofs were used is uncertain. Mr Bonomi believes that they were, and a few sculptures seem to support his view. Of the private houses nothing, of course, remains; but they are represented on the slabs as being of several stories in height, the ground floor as usual having only a door and no windows. All have flat roofs, and we gather from one of the bas-reliefs, which represents a town on fire, that these roofs were made, just as they now are, with thick layers of earth on strong beams. These roofs are well-nigh fire proof, and the flames are represented as stopped by them, and coming out of the windows. No remains of a window, or, so far as we are aware, of an internal staircase, have been found.

Of the fortifications we know much more. In the north wall of Nimroud fifty-eight towers have been traced, and at Kouyunjik there are large remains of three walls, the lower part being of stone, and the upper of sun-dried bricks. At Khorsabad there are the remains of a wall, still 40 feet high, built of blocks of stone 3 to 4 feet thick, and the evidences wanting as to the finishing of these is completely supplied by the sculptures, which show an extraordinary resemblance to mediæval works of the same class. Tier upon tier of walls are represented, enclosing a great tower or keep in the centre. The entrances are great arched gateways flanked by square towers. These and the other towers have overhanging parapets just like the mediæval machicolations, and are finished at top with battlements, remains of which have been found at Nimroud and Kouyunjik, and at Kaleh Shergat, the supposed capital of Assyria before Nineveh.

Of temples distinct from the palace we have a few supposed remains, but little is absolutely known as to their general form.

But in Chaldea there are some enormous masses of ruins, evidently remains of the vast mounds which formed the substructure of their temples. The grandest of all these and the most interesting is the Birs Nimroud, near Babylon, which has been identified as the temple of the Seven Spheres at Borsippa. This was reconstructed by Nebuchadnezzar, as appears by a well-known inscription. Another example is at Mugeyer, which was 198 feet by 133 feet at the base, and is even now 70 feet high, and it is clear that both it and the Birs were built with diminishing stages, presenting a series of grand platforms, decreasing in length as they ascended, and leaving a comparatively small one at top for the temple cell. This has been found, it is supposed, at the Birs Nimroud, of vitrified brick.

The most interesting parts of the Assyrian edifices are the finishings. The pavements were sometimes of sun-dried bricks, at other times of baked bricks, or of alabaster slabs laid in bitumen. At Khorsabad there was one in a single block 13 feet square, and 3 ft. 11 in. thick, and at the Nimroud temple there were two slabs, one 19 ft. 6 in. by 12 feet, and the other 21 feet by 16 feet, and 1 ft. 1 in. thick, both sides covered with inscriptions. Of ornamental pavements there are admirable examples from Kouyunjik at the British Museum, and from Khorsabad at the Louvre, both covered with delicate carving in alabaster of nearly the same pattern. It is difficult to conceive how such delicate work could have been used as paving, and still retain its beautiful sharpness; for it was not filled in to protect the pattern. Directly above the pavement came the sculptured slabs, which are so numerous that at Kouyunjik alone there are some 2 miles in length of them. They are generally about 10 feet high from the ground, and are carved in alabaster. Many of them show traces of having been decorated with colours. Connected with these sculptures were the great winged animals which stand one on each side of the portals of the palaces. Some of the grandest have the body and legs of a bull, with an enormous pair of wings projecting from the shoulders, high over their backs, and covering the breast. They have human heads, bull's ears with large ear-rings, and horns, winding from the brows upwards, and encircling a coronet of leaves, bound by a fillet of roses. They stood in pairs on each side of the palace doorways, and it is thought by some that generally there were no doors or lintels, all being open to the roof and enclosed with curtains. But doors were sometimes used, as the places or stages, from the early structures of wood, and thus originated a style, grand, picturesque, and in its ruins beautiful, but well-nigh isolated in the history of art, there being nothing from which it was quite copied, and nothing which seems quite to have sprung from it.

The few remains which exist of a later date are separated from the above as widely in architectural forms as in chronology. Neither the Greek Seleucidæ nor the Parthian Arsacidæ have left any buildings (of importance at least) which can be identified; and the well-known edifices at Serbistan, Firouzabad, and Ctesiphon, are late in the time of the Sassanidæ. The two former edifices have domes rising from square bases and lighted by small apertures, as Victor Place suggests was the case at Khorsabad, and each is approached, as was the Khorsabad palace, through a deep vaulted entrance. At Ctesiphon this vault is 115 feet deep, 72 wide, and 85 high. Of the famous palace at Dastageod (Artemita), 60 miles north of Ctesiphon, described by the Byzantine writer, Theophanes, no remains are known to exist; but Dr Tristram has discovered at Mashita, in the land of Moab, a palace with its enclosing walls, richly decorated with carving, &c., which Mr Ferguson considers to have been built by Chosroes shortly before the Arab invasion. The edifice is minutely described and illustrated in Tristram's *Land of Moab*.

Architecture of Asia Minor.

Little was known of the antiquities of Asia Minor until, in 1838 and 1840, Sir C. Fellows discovered in its north-western corner eleven ruined and deserted cities. It was reasonable to think that in these we should have the missing link between Assyrian and Greek art. But although a few of the sculptures show traces of Assyrian influence, and though the later structures are very similar to those of Greece, the productions of native art seem quite isolated and peculiar. The most ancient remains are considerably later than such masterpieces of skill as the tomb of Agamemnon at Mycenæ, and the great works of later times were erected long after the Parthenon.

The earliest works remaining are singularly like the Etruscan graves so often found in Italy. Perhaps the first of these is the tomb at Tantalais near Smyrna, which has simply a square chamber, ceiled with a pointed arch, formed with oversailing courses, and all covered with a tumulus. Like to it is the tomb of Alyattes, king of Lydia, on the bank of the Hermus, near Sardis. It has also one chamber, 11 feet by 8, and 7 feet high, in the centre of a circular pyramid, not sloping directly from the ground, as in Egypt, but having a high moulded stereobate, at the starting, some ¾ mile round. This structure would create no surprise if found in Tuscany; and still more to increase the resemblance to Etruscan work, it appears to have been surmounted by five stone pillars. Of the tombs which belong to the races between the above and the time when Greek art was introduced or was invented, the rudest are perhaps, to be found in Caria. They are sarcophagi, and those at Olinda, *e.g.*, are of enormous size, ranged on each side of the street leading to the city. In the simplest form a cavity was made in a great stone for the body, and a heavy lid put over it, coped, or rising as a pediment in centre. Generally they were plain and oblong in shape. In Lycia, chiefly on the banks of the Xanthus, are found other sepulchres of remarkably singular form. We look in vain for their prototypes, or anything copied from them. The most simple are cut in the steep rocks which invariably overhang the cities, and are often curiously like Elizabethan windows, with mullions and panels. Some have a Gothic shaped top, which is also peculiar to Lycia [illegible] the kind [illegible]mission of Messrs Nisbet [illegible] pediment [illegible] them show evident traces of having been copied in stone from wooden originals. For they are shown with joints put together with dovetails and pins, and with cornices like the ends of round trees; not actually so constructed, but all carved out of one solid mass. The designs of these rock-cut tombs were then still further elaborated in the detached monuments. The earlier ones, indeed, are much more simple, and are known as the obelisk tombs, being merely great high blocks of stone or marble, standing on a square base and surmounted by a cornice. They have not the real obelisk form, and have got the name merely on account of their height. In the grander works, the obelisk is surmounted by a sarcophagus of great size, coped with the pointed arch, with mullions and panels as above detailed, and all bearing signs of a wooden origin. Some are of enormous size, the stones weighing 50 to 80 tons. The different parts of the edifice were hollowed out for coffins, a plan of sepulture little known elsewhere.[1] These singular tombs are found all through Lycia, but a beautiful variety of them, found only at Xanthus, has the ridge stone grooved to receive an ornamental crest, sometimes richly sculptured. These singular structures are separated by a wide interval from the forms of Greek art; but that their design was, to some extent, adopted and used by the Greeks, we have various signal proofs. The Harpy tomb, whose sculptures are in the British Museum, is supposed to have been erected so late even as after the capture of Xanthus by the Persians in 547. It has the chief Lycian peculiarities, a base 6 feet high, carrying a square shaft 17 feet high in one block, weighing some 80 tons, and surmounted by a cap stone of 15 tons weight. Near the top, on each face, was carved the famous Harpy frieze. Near this was another, known as the Chimæra tomb, having the Gothic headed sarcophagus, and with a sculptured crest. And near to this again, was another of a similar kind, called the Winged Horse tomb. Doubtless these and other works, both in Lycia and Caria, were wrought by Lycian workmen under Greek guidance, but they seem to have made no lasting impression upon the architecture of the Greeks.

Grecian Architecture.

Hitherto, we have found that, in each country, the artistic forms used in the earliest periods descended to later times, which embodied to some extent the traditionary forms bequeathed to them. Even the Egyptian pyramids, unarchitectural as they are, were copied down to the 7th or 8th century in Nubia, and the earliest columnar architecture clearly shows itself as simply the beginning of a series of works extending from 2000 B.C. even to the Cæsars. But in Greece the earliest works are entirely separated from the later by an absolute break both in architectural forms and construction. In various parts of Greece and of Italy, specimens of rude walling are found of such remote antiquity, that they are, as by common consent, referred to the fabulous ages, and, for want of a more distinctive term, are called Cyclopean. Now it appears, from the concurring evidence, in the opinion of most antiquaries, that a people who have been called Pelasgi, or sailors, migrated from Asia Minor, or the coast of Syria, at a very early period, and possessed themselves of various countries, some of which were unoccupied, and [illegible] pro-

[1] The following inscription, though belonging to Greek times, shows how this was done:—"In the sarcophagus I buried Barilla my wife; and I wish myself to be put into the sarcophagus, and nobody else [illegible] In the first compartment lying under it I wish my second wife [illegible] Polychromas my [illegible] to be buried; in the other are to be put [illegible] other children [illegible] nobody else is to be put either into the sarco[illegible] [illegible] the [illegible] employment of glazed coloured bricks.

others inhabited by Celtic tribes. Professor Heeren, who affixes dates to the various migrations, expressly says that the Pelasgi were of Asiatic origin. "Their first arrival in the Peloponnesus was under Inachus, about 1800 B.C., and according to their own traditions," he says, "they made their first appearance in this quarter as uncultivated savages. They must, however, at an early period have made some progress towards civilisation, since the most ancient states, Argos and Sicyon, owed their origin to them; and to them, perhaps with great probability, are attributed the remains of those most ancient monuments generally termed Cyclopic." He adds, that the Hellenes, a people of Asiatic origin also, expelled the Pelasgi from almost every part of Greece, about 300 years after their first occupation of it; the latter keeping their footing only in Arcadia and in the land of Dodona, whilst some of them migrated to Italy, and others to Crete and various islands. The arrival of the Egyptian and Phœnician colonies in Greece, Professor Heeren thinks, was between 1600 and 1400 B.C. The most ancient specimen of Cyclopic walling is found at Tiryns, near Mycenæ. It is composed of huge masses of rock roughly hewn and piled up together, with the interstices at the angles filled up by small stones, but without mortar or cement of any kind. The next species is in stones of various sizes also, shaped polygonally, and fitted with nicety one to another, but not laid in courses. Specimens of this are found at Iulis and Delphi, as well as at the places already mentioned, in Greece, and in various parts of Italy, particularly at Cossa, a town of the Volsci. This also was constructed without mortar. The mode of building walls, which took the place of that, is not called Cyclopean; it is in parallel courses of rectangular stones, of unequal size, but of the same height. This was, however, often used in combination with the polygonal, as in one very beautiful specimen at Rhamnus. The parallel masonry is common in the Phocian cities, and in some parts of Bœotia and Argolis. To that succeeded the mode most common in, and which was chiefly confined to, Attica. It consists of horizontal courses of masonry, not always of the same height, but composed of rectangular stones.

FIG. 42.—Wall at Tiryns, Greece; from Waring's *Stone Monuments.*

The oldest existing structure in Greece of regular form is of far superior construction to the Cyclopean walling, and must be referred to early colonists. It is at Mycenæ, and consists of two subterranean chambers, one much larger than the other. The outer and larger one is circular, and entered by a huge d[illegible]ay at the end of a long avenue [illegible]lossal walls, buil[illegible] nearly parallel [illegible]ses of rect- [illegible] roofs were made, just as they now are, with thick without mortar. Its external effect is that of an excavation, though the structure of the front is evident; and internally it assumes the form of an immense lime-kiln; its vertical section being of a conical form, with nearly parabolic curves, like a pointed arch. The construction of this edifice was thought to afford clear evidence that the Greeks were acquainted with the properties of the arch; but in the most material point this was destroyed on finding that it consisted of parallel projecting courses of stone in horizontal layers, in the manner called by our workmen battering, or perhaps more correctly, corbelling. It proves, however, that its architect understood the principle of the arch in its horizontal position; for Mr Cockerell discovered, by excavations above it, that the diminishing rings of which the dome is composed were complete in themselves for withstanding outward pressure; the joints of the stones being partly wrought radiating, and partly rendered so by wedges of small stones driven tightly into them behind. The apex is formed, not by a key-stone, for the construction does not admit of that, but by a covering stone, which is merely laid on the course immediately below it. It may be added, that internally the lower projecting angles of the stones are worked off to follow the general outline. Though this is the largest and most perfect, its internal diameter at the base being 48 ft. 6 in., and its height from the floor to the covering stone 45 feet, yet edifices exhibiting similar structure are found in many other places in Greece itself, in Egypt, in Sicily, and in Italy. They all, however, tend to prove, that the principle of the construction of the vertical arch was unknown at the time of their erection in all those countries; and their erection is evidently of the most remote antiquity. But neither could the mechanical powers have been unknown to their constructors. In the edifice which we have described, and which is thought by some to be the treasury of Atreus, or the tomb of his son Agamemnon, mentioned by Pausanias as existing among the ruins of Mycenæ in his time, the inner lintel of the doorway is 27 feet in length, 16 feet deep, and nearly 4 feet thick, weighing, it is computed, upwards of 130 tons; and the lintel of the Gate of the Lions in the Acropolis of the same city, is, from its immense magnitude, also strongly illustrative of the great mechanical skill of the people of those times.

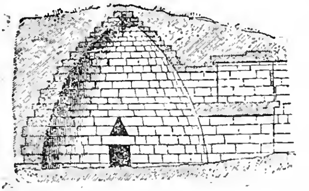

FIG. 43.—Treasury of Atreus, Mycenæ; section. From Waring's *Stone Monuments*

As no nation has ever equalled the Egyptians in the extent and magnitude of their architectural monuments, neither have the Greeks been surpassed in the exquisite beauty of form and proportion, in the extreme simplicity and perfect harmony, which pervade every part of their structures. Unfortunately these monuments are known to us only by their ruins, for there is not a Grecian building remaining in a perfect state. In Greece proper, at least, this was not so until a comparatively recent date, viz., that of the war between the Venetians and Turks. The Parthenon itself was nearly perfect until that time, when it was shattered by an explosion of gunpowder (1687).

First in importance in Grecian architecture is the use of the three orders, Doric, Ionic, and Corinthian, with the peculiar mouldings, &c., connected with each. The Doric and Ionic columns, rudely drawn, appear on the early Etruscan or Greek vases. They are very slender, with large projecting capitals and with entablatures, which indicate pretty clearly copies from a construction of wood. Buildings, much as these, and all of wood, are described by Sir C. Fellows as still being constructed in Lycia. That columns of wood were used in the ancient temples of Greece we know from such notices as we have, *e.g.*, of an old wooden column which was preserved in the temple of Juno at Olympia, as h[illegible]ing been [illegible] of those of a form[illegible] [illegible]. By [illegible] doubt sometimes used, as the place at in, recesses for the bolts, hinges, pins, or sockets have been found; and Mr Smith has discovered a doorway with its actual lintel, now in the British Museum.

Above the sculptured slabs decorations have been found of various kinds. The most lasting seem to have been of baked bricks richly coloured and glazed. At the city gate of Khorsabad blue glazed tiles with yellow reliefs have been found. Victor Place found also that the lower part of the walls near the gate were faced with coloured enamelled bricks, having human figures, lions, &c., within an ornamental border. The arch over the gateway was also richly decorated with glazed tiles. Large remains of coloured decoration in plaster have also been found at Nimroud, &c. They were of figures outlined in black on a blue ground, and below the outer coat of plaster more extensive decorations have been found on an earlier coat. They were of various colours on a pale yellow ground. In other cases they had merely a black outline and were uncoloured. Now the difference of age between the several structures is some centuries, and it is curious to find that the earliest art works, viz., those in the N.W. palace, are the best in point of variety of detail and ornament, in severity of style and purity of outline. The later have extreme delicacy and minuteness, truth to nature and vigour of treatment, particularly in the animals, but they want, in the opinion of Mr Layard, the vigour of the old decorations. Of external decorations we have a striking account in the inscription relating to the Birs Nimroud, in which the several stages are described as being coloured as follows:—the lowest, black; the others in succession, orange, red, yellow, green, and blue. This vivid colouring may be explained by a discovery made by Mr Loftus at Warka of a wall which

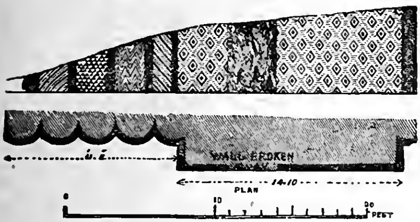

Fig. 39.—Elevation and Plan of Terra-Cotta Cone wall, Warka.[1]

was richly decorated in geometrical patterns by means of small earthenware cones, the wide ends outwards and en-

Fig. 40.—Terra-Cotta Cone, reduced by one-seventh.

amelled in different colours; also by Victor Place's discovery at Khorsabad of four stages of a temple coloured in succession white, black, red, and blue.

In the Assyrian and Chaldean buildings little use was made of marble, granite, or stone, the greater part of the edifices being built with bricks,—the lower parts with burnt bricks put together with bitumen, and the rest with crude bricks and slime. Sometimes the walls were faced with burnt bricks. One wall has been found with 10 feet in thickness of burnt brick facing, and 28 feet of crude bricking.

In Assyrian art generally there is little analogy to that of Egypt. There is some slight resemblance in the mouldings and in a few of the ornaments, but in Assyria there are no forests of columns, no grand pylons, no enormous cloistered court, and nothing to equal the gigantic pyramids or tombs of Egypt. The sphinx is superseded by the winged bull, and the slightly cut intaglio by the magnificently sculptured slab. In these early Assyrian structures there is art at a high stage of perfection, but we have no means of discovering the steps by which it was attained.

[1] Figs. 39, 40, and 41 are from Loftus's *Chaldæa and Susiana*, by the kind permission of Messrs Nisbet, the publishers.

Persian Architecture.

Persia was one of the greatest of ancient nations. At one time it embraced all Upper Asia, and Asia Minor, Phœnicia, Egypt, Thrace, and Macedonia, and though the greatness of its glory has departed, it was still a great living nation even in the 18th century when its king Nadir Shah invaded India. Compared thus with Egypt, Assyria, and Babylonia, long since extinct, it has had a wonderful existence, reaching down from Cyrus to our own time.

We know little of its early history. It cannot be doubted, that long before the rise of the Persian power, mighty kingdoms existed in these regions, and particularly in the eastern part of Bactria, yet of those kingdoms we have by no means a consistent or chronological history—nothing but a few fragments. It is probable that from dynasties which ruled in Media properly so called, immediately previous to the Persians, the style of architecture may have been in some measure derived, though indeed we know of no remains of earlier date than those which are properly called Persian.

Of the early times of the empire no authentic remains exist, except those of the tomb of its founder, Cyrus, at Murgab or Pasargadæ (east of the head of the Persian Gulf), and some of the walls, &c., of the ancient capital, Ecbatana, in North Media. The former is still in a wonderful state of preservation, but it can scarcely be reckoned amongst Persian edifices, as it is clearly a work designed by some architect from a Greek colony of Asia Minor. The tomb stands on seven bold steps of white marble, the lowest being 43 feet by 37 feet. The tomb itself is 21 feet by 16 ft. 5 in. outside, with bold mouldings to the door; it has a sloping roof of marble, with a pediment at each end, enriched with mouldings. The chamber itself is only 7 feet by 10, the walls being built up with thick blocks of marble. Near the tomb was the famous inscription, "I am Cyrus the king, the Achæmenian," and though this is now wanting, recent discoveries seem to have disinterred the stone which had borne it, and which had been torn away. Round the tomb outside had evidently been a colonnade of 24 columns, fragments of which, with the bases, alone remain. They resemble those commonly used by the Greeks. This singular structure seems to have been unique in Persia. It is evidently the work of a foreigner, although the outline may represent, as is supposed, a temple. The famous walls of Ecbatana, the ancient capital, are said to have been 75 feet broad and 105 high, its stones 9 feet by 4 ft. 6 in., and its gateways 100 feet high and 60 wide. The remains, however, show walls only 12 feet wide, stones only 2 feet by 1 ft. 2 in., and a gateway only 12 feet high and 10 feet wide. They deserve particular mention on account of their being among the earliest examples of constructive colouring on a grand scale. The walls are said to have been seven in number, one over the other on the sides of a conical hill, and coloured in succession, white, black, scarlet, blue, orange, silver, and the innermost gilt. From what has been discovered at Warka (see above), it is possible that this gorgeous description may have been founded on fact; and we know that the Easterns in early times were profuse in their employment of glazed coloured bricks.

Of the domestic structures of the same early time we have no remains, but it would appear that the grander buildings had courts, surrounded by colonnades, somewhat in the Egyptian style, the columns and beams being of wood, coloured, and sometimes gilt, or coated with metal. Above was a sloping roof. We learn particularly from this that the Persian or Median architects were thoroughly well used to a wooden construction.

Some 50 years after Cyrus, the chief buildings at Persepolis and Susa were constructed; large portions still remain, and form some of the grandest ruins in existence. Of these we have measured drawings worked out by Messrs Texier and Flandin, from which we derive the chief part of our knowledge, although we have very interesting accounts by Sir R. K. Porter, Mr Rich, Mr Morier, Mr Loftus, &c. The existing buildings at Persepolis occupy a remarkable position on an elevated platform (partly, it would seem, artificial) at the foot of a steep rock in the face of which were cut out the tomb chambers of the Persian kings. The platform was 1425 feet on the west side, and 926 feet on the north, about the size of the Horticultural Gardens in London, including the arcades and conservatory. It was raised about 40 feet above the level of the adjoining country, and faced with a wall, built with stones of an immense size. The platform was approached by the grandest flight of steps in the world, each step being 22 feet long. Having scaled these, the stranger would pass through the first building, viz., the Propylæum of Xerxes, a building whose remains have given rise to several theories as to its original plan and purpose. There remain two grand gateways 24 feet apart, with portions, more or less perfect, between these, of four columns 45 feet high. The gateways had openings of 13 feet, and each of their piers was partly composed of bulls, admirably executed, and strikingly like the Assyrian sculptures at the Louvre from Khorsabad. The human heads of these animals are crowned with coronets of leaves, and from the top of the coronets to the hoofs, the animal measures 19 feet. Nothing further has been discovered which would throw light on the general plan of the building. Mr Fergusson believes that it was enclosed and roofed, and served as a justice hall, or place of assembly at the entrance of the palace. M. Flandin's idea is, that the structure was a mere open portico roofed, but without walls, except perhaps for a few feet in height. Through this structure was the entrance to the grand palace, the Chehil Minar, *i.e.*, hall of 40 columns, an Eastern mode of expressing a great many, as there were really 72. It was approached by a magnificent staircase, each step of which served as a pedestal to a figure (1 ft. 9 in. high) in bas-relief, the whole representing a procession, and of great value as giving the varied costumes, &c., of the period. The columns of the palace are arranged in four divisions, viz., one of 36 columns in the centre, and three each of 12 columns in two rows, divided from the centre by a space of about 60 feet. Of all these only 10 are standing, but the bases of most remain, and the whole ground is covered with the ruins of the columns that have fallen. Their height varied from 60 feet (including capital and base) in the front division, to 67 ft. 4 in. in the centre one. In these columns there is an advance upon the architecture of Egypt, for they have bases, richly carved, and capitals of a form unknown to our art, before or since. The typical form is that of the double-headed bull with a deep cavity between the heads, evidently intended to hold a beam. There is a quaint grandeur about these columns, from their design and their gigantic size. The capitals of one division, the western, are 7 feet high, and 12 ft. 2 in. wide, whilst the shafts, 54 ft. 10 in. high, are each composed of only four great marble blocks. Unfortunately we have only fragments of these buildings, with no history or tradition to guide us as to their perfect forms. There are no walls, no doorways, and no roofs. Mr Fergusson in his restoration places walls between the several divisions, and thus forms them into one grand, enclosed structure, with a mass of columns in the centre, and three porticoes at the sides. He also believes that there was an upper story, to which, indeed, some Persian writers have alluded. Sir R. K. Porter's restoration, with that of Messrs Flandin, Coste, and Texier, is quite different. They believe that the four groups of columns were isolated and had no enclosing walls, but were simply screened by curtains; that the centre division had a flat roof with an opening in the centre, protected by an awning, for light and ventilation; that the roof, cornices, and superstructure of all kinds, were of wood, as no fragment of a stone cornice, lintel, or tile has been found.

Now it so happens that at Susa there was another great palace, similar, or nearly so, in size and plan to that at Persepolis, and with an inscription showing it to have been built by Artaxerxes Mnemon, son of Xerxes. The height of the columns is unknown, but the capitals and bases correspond closely with those at Persepolis. The capitals have singular volutes under the double bull's heads, the whole being 28 feet high, the capitals alone being thus as high as the columns and bases together of St Martin's, London. Mr Loftus examined this structure carefully, and satisfied himself that no walls had ever existed. In addition to this an ancient drain has been found at Persepolis, in the very line which one of the main walls must have occupied. Mr Loftus therefore agrees with Sir R. K. Porter and the others in their restoration. The description in Esther i. 6, has been supposed to refer to this palace. Two other structures at Persepolis were really enclosed—viz., the palaces of Darius and Xerxes. Each has the four divisions of columns, as at the Chehil Minar and Susa; but the jambs to the doors and other portions of the enclosure still remain. These were clearly places for habitation. A still larger enclosed building, the hall of 100 columns, has also left gigantic fragments. The size and arrangement are unknown; but it must have been about 225 feet square, and enclosed by walls, some of the doorways and blank windows of which remain. The excavated tombs of the kings, high up in the face of the mountain, just as described by Diodorus, are the only other important remains of ancient Persia. Remains at Susa.

FIG. 41. — Compound Capital and Base of Column at Susa.

To sum up as to our knowledge of Persian art, the greater part of the remains are columnar, not an edifice is built on the Assyrian plan, and there is little to remind us of Assyria except the human headed bull. The doors and windows somewhat resemble those of Egypt. They have the same plain architrave, the large roll, cavetto, and fillet at top. But the sides of the portals are straight; there are no massive pylons, and the whole character of the columns, bases, and capitals is utterly unlike any known remains of Egyptian or Assyrian art. By what stages the Persian architects arrived at the singular work at Persepolis and Susa we cannot now judge. All we know is that Persian art was developed contemporaneously with that of Greece, though with utterly different results. The elegant form of the Greek temples, the curve of the Assyrian arch, would seem to have been unknown to the Persians, who, it appears likely, worked out their latest forms by gradual

these light wooden structures we see the origin of the orders, by the earliest stone columns known being the most massive and if we turn to Egypt, the mother of the arts and sciences, we shall find many things in some of the most ancient structures which may have furnished an idea of the Doric arrangements to the fertile imagination of the Greek. Allusion has already been made to the well-known façade at Beni Hassan, on the Nile, as giving us a very likely prototype of the Grecian Doric column.

Of the triglyph, the most distinguishing part of the Doric entablature, there are many indications in the early works of Upper Egypt; and in the structures of the Ptolemies they are still more evident, though it may be objected that in them the indications were borrowed from the Greeks after the Macedonian conquest. But it must be borne in mind that the Egyptian nation did not change its character, religion, or usages by the change of its governors; and the Egyptians were, through the whole period of their existence as a nation, an originating and not an imitative people; whereas the Greeks seized on a beauty wherever they found one, and made it their own by improving it. To the question, why the Greeks cannot be allowed to have originated that beautiful style of architecture which they brought to the perfection it displays in their works, it may be sufficient to answer, that it would be against the common course of events if it were so. It is remarkable that, in Greece, the earliest specimen of columnar architecture that presents itself displays the chief characteristics which are found in works of periods when learning and civilisation were at their acme in that country

It will be convenient to give here at the outset a list of the principal Greek buildings.

Tabular List of Principal Greek Temples, &c.[1]

Site of Temple, &c.	Date. B.C.		Cols. Front.	Cols. Flank.	Order.

The Grecian Doric (Plates VIII., IX., X.)

Vitruvius gives several accounts of the origin of the Greek Doric order. He states first that "Dorus (the son of Hellenus and of the nymph Orseis), king of Achaia and of all the Peloponnesus, having formerly built a temple to Juno in the ancient city of Argos, this temple was found by chance to be in that manner which we call Doric." In another place he deduces the arrangements of the order from those of a primitive log hut, settling with the utmost precision what, in the latter, suggested the various parts in the former. But he also tells us that the Doric column was modelled by the Grecian colonists in Asia Minor in the proportions of a human figure, and was made six diameters in height, because a man was found to be 6 times the length of his foot. But this story, even supposing it to be rational, does not coincide with the Greek Doric at all, but, if with anything, with the Roman.

In the Greek examples, this order may be divided into three parts, stylobate, column, and entablature (Plate VIII. fig. 4). The stylobate is from two-thirds to a whole diameter of the column in height, in three equal courses, which recede gradually the one above from the one below it, and on the floor or upper step the column rests. That graduation, it may be remarked, does not appear to have been made by the ancients to facilitate the access to the floor of the stoa or portico, but on the principle of the spreading footings of a wall, to give both real and apparent firmness to the structure, both of which it does in an eminent degree.

The column varies in height in different examples, from four diameters, as at Corinth, to six diameters, as at Sunium. Of this the capital, including the necking, is rather less than half a diameter: in those cases in which a necking does not exist, the capital itself occupies nearly the same proportion (Plate VIII. figs. 4 and 9; Plate IX. fig. 4). The shaft diminishes in a slightly curved line, called an entasis, from its base or inferior diameter upwards to the hypotrachelium, where the diameter is from two-thirds to four-fifths of that at the base. It is the inferior diameter that is always intended when the term is used as a measure of proportion. The capital consists of a necking, an echinus or ovolo, and an abacus; the necking is about one-fifth of the height of the capital, and the other two members equally divide the remaining four-fifths; when there is no necking, the ovolo occupies the greater proportion of the whole height. The abacus is a square tablet, whose sides are rather more than the inferior diameter of the column. The corbelling of the ovolo adapts it to both the diminished head of the shaft and the extended abacus, flowing into the one, and forming a bed for the other by means of a graceful cyma-reversa; but its lower part is encircled by three or four rings or annulets, which are variously formed in different examples, and which give the echinus form to the great moulding, although it is, as we have said, part of a cyma-reversa. (Figs. 6 and 7 of Plates VIII. and IX.) The shaft is divided generally into twenty flutes; but there are several examples with sixteen, and there is one with twenty-four. The flutes are sometimes segments of circles, sometimes semi-ellipses, and sometimes eccentric curves (Plate VIII. fig. 12; Plate IX. figs. 8, 14.) They always meet in an arris or edge, and follow the entasis and diminution of the column up through the hypotrachelium to the annulets, under which they finish, sometimes with a straight and sometimes with a curved head. At the base they detail on the pavement or floor of the stylobate. In one example at Segesta the columns are not fluted at all, and in two others, at Cnidus and Delos, the flutes are marked at top and bottom only, but in these examples the columns were possibly not finished.

The third part of the order, the entablature, ranges in various examples from one diameter and three-quarters to rather more than two diameters in height, of which about four-fifths is nearly equally divided between the architrave and frieze, while the cornice occupies the remaining one-fifth: this is in some cases exactly the distribution of the entablature. (See Plate VIII. fig. 5; Plate IX. fig. 5.)

[1] The angle columns are counted each way.

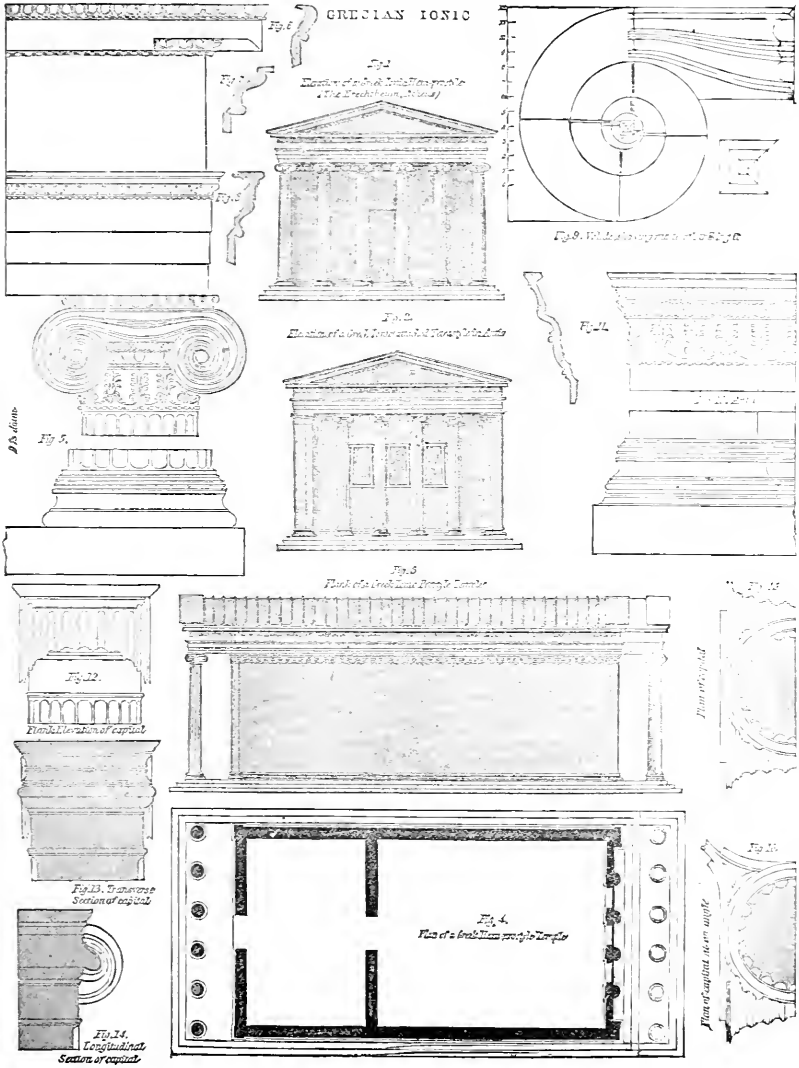
The architrave is in one broad face, four-fifths, and sometimes five-sixths of its whole height; and the remaining fifth or sixth is given to a projecting continuous fillet called the tænia, which occupies one-half the space, and a regula or small lintel attached to it, in lengths equal to the breadth of the triglyphs above in the frieze. From the regulæ six small cylindrical drops, called guttæ, depend. There are examples to the contrary, but it may be taken as a general rule, that the architrave is not in the same vertical line with the upper face of the shaft, or its circumferential line, at the superior diameter, but is projected nearly so much as to impend the line or face of the column at the base. In one example only is the architrave known to be sculptured, viz., at Assos, where it has bas-reliefs of bulls fighting. The frieze, vertically, is plain about six-sevenths of its whole height, and is bounded above by a fascia, slightly projecting from it, which occupies the remaining seventh. Horizontally, however, it is divided into triglyphs and metopes, which regulate the intercolumniations; the former being nearly a semidiameter in width, and the latter (the space interposed between two triglyphs) generally an exact square, its breadth being equal to the whole height of the frieze, including the fascia. This latter breaks round the triglyphs horizontally, and is a little increased in depth on them. These metopes are shown on the vases to be holes between the ends of beams, and that the metopes were, at one time, open, seems to be proved by a passage in Euripides, who lived during the construction of the Parthenon. No example, however, early or late, remains to support this view. Each glyph, of which there are two whole ones and two halves to every tablet, is one-fifth of the width of the whole, and the interglyphs are each one-seventh of the whole tablet or triglyph. The glyphs detail on the tænia of the architrave, but are variously finished above. In some examples they are nearly square-headed, with the angles rounded off; in others the heads are regular curves, from a flat segment to a semi-ellipse. The semiglyphs are finished above in a manner peculiar to themselves, with a turn or drop; but hardly two examples correspond in that particular. The tablets in which the glyphs are cut are vertical to the face of the architrave, the metopes recede from them like sunk panels; these are often charged with sculptures, and indeed almost appear contrived to receive them. The third and crowning part of the entablature, the cornice, in what may be considered the best examples, projects from the face of the triglyphs and architrave about its own height. Vertically, it is divided into four equal parts, one of which is given to a square projecting fillet at the top, with a small congeries of mouldings, different, and differently proportioned to each other, in various examples. Two other parts are given to the corona, and the remaining fourth to a narrow sunk face below it, with the mutules and their guttæ. These latter form the soffit or planceer of the cornice, which is not horizontal or at right angles to the vertical face of the entablature generally, but is cut up inwards at an angle of about 80°. The width of the mutules themselves is regulated by that of the triglyphs over which they are placed, to which it is exactly equal. They are ornamented each with three rows of six small cylinders, similar to those which depend from the regulæ under the triglyphs and on the architrave. There is twice the number of mutules that there is of triglyphs, one of the former being placed over every metope also in the manner the examples indicate.

This completes the Greek Doric order according to the generally received sense of the term; but there are other parts necessary to it. In the front or on the ends of a temple, or over a portico, a pediment is placed (Plate IX. fig. 1). Its intention is to enclose the ends of the roof, but it forms no less a part of the architectural composition. In reason, it should be raised as much as the roof required; but when the span is great that would be unsightly; and reference appears to have been made to the common standard of proportion, as the pediments of most Doric temples are found to be about one diameter and a half in height at the apex of the tympanum, which in a hexastyle arrangement makes an angle at the base of about 14°, and in an octastyle about $12\frac{1}{2}$°. The pediment is covered by the cornice, without its mutules, rising from the point of its crowning fillet, so that no part of it is repeated in profile. Another moulding, however, is superimposed: sometimes this is an ovolo with a fillet over it, and sometimes a cymatium. It varies much in its proportion to the cornice, but in the best examples it is about one-half the depth of the latter without its mutules. Ornaments of various kinds, statues or foliage, are believed to have been placed on the apices and at the feet of pediments as acroteria. Of these, however, we have the remains of one only (a very beautiful one), viz., at Ægina; but indications of the plinths or blocks which may have received them exist, and such things appear represented on ancient coins and medallions. The tympana of pediments are well known as receptacles of ornamental sculpture. On the flank of a Doric temple, the cornice supported a row of ornamented tiles called antefixæ. These formed a rich and appropriate ornament, but they rather belonged to the roof than to the columnar arrangement or order. The antefixæ covered the ends of the joint-tiles as the pediments did those of the roofs; and corresponding ornaments called stelai rose out of the apices of the joint-tiles, forming a highly enriched ridge (see Plate VIII. fig. 1).

A secondary Doric order arises in the disposition of a Grecian temple, from the columns of the pronaos and the inner part of the external entablature continued and repeated. Of this the frieze is generally without triglyphs, though there may be regulæ and guttæ on the architrave. The fascia of the frieze is either moulded or enriched on the face; and, instead of a cornice, the beams of the ceiling are laid at equal intervals to support sunk panels or coffers, in which there may be flowers or other enrichments (Plate VIII. fig. 8).

Propriety in the composition and arrangement of antæ is as necessary to the perfection of the Doric order as to that of the columnar ordinance itself, especially if the latter be *in antis*. Slight projections are made on the end and side faces of a wall, so as to form a species of pilaster, whose front shall be nearly equal to the diameter of the columns to which it is attached, exactly equal indeed to the soffit of the entablature, whose faces have been described as impending the circumferential line of the column at a little above its base. This rests on the stylobate in the same manner as the columns do, with sometimes a small continuous moulding as a base; and its capital is a congeries of mouldings, about the depth of the abacus, with a plain fascia corresponding to the ovolo of the columnar capital. The entablature of the order to which it is attached rests on it, and, continuing along the flank of the building, is received by a similar combination at the other end. These, it may be remarked, were seldom diminished or fluted, an example at Pæstum being about the only exception. Being projections from and upon the ends and faces of walls, they could not be diminished without involving an absurdity, and fluting on a straight surface must be productive of monotony, as the flutes can only project a series of equal and parallel shadows. Not so, however, with columns, on whose rotund surface fluting produces a beautiful variety of light and shade in all their gradations, which it could not possess without that enrichment; for on a plain

GRECIAN IONIC



column neither are the lights so bright nor the shadows so dark as in the former case, nor are they so finely diffused over the whole surface in the one as in the other.

In the Parthenon the antæ, as well as the columns, are without bases. In all other examples the base line of the antæ is marked by a few small mouldings. In the only example which occurs in the ancient architectural remains of attached Doric columns—that of the pseudo-peripteral temple of Jupiter Olympius at Agrigentum—the stylobate is peculiarly arranged. The upper gradus is grooved, and detailed round the columns and along the walls between them; and a congeries of vertically arranged mouldings and fillets rests on it, and receives the base of the column.

As before stated, the earliest examples of columns are the heaviest; they are also the most tapering, and there are some other details which help us in identifying the date of a Doric edifice in Greece proper. The hypotrachelium in early examples, as at Corinth, has three grooves; in later, as the Parthenon, only one. The contour also of the chief member, the echinus, varied at different dates. In the earliest it was full and round, as at Corinth, and at Assos (the latter having the greatest curve of any known example); sometimes possibly, as at Segesta, struck with the compass, but almost always part of a conic section (parabola). In later times it became less curved, and in the finest examples almost flat, as in the Propylæum and Parthenon, but still forming part of a very delicate curve (hyperbola). In one case, at Selinus, where, to an inexperienced eye, the whole temple would appear to be of the same date, the differences alluded to contrast very strongly with each other. In the very late times of Greek work, when art became debased, the coarse round form of earlier work is exhibited, as in the Agora. The width of the abacus in early examples, as Corinth, is as much as two-sevenths the height of the shaft and cap. In later examples it diminishes to one-fifth. And as the column, so the entablature was more massive in the early examples, except in the colonies, where the old proportions continued to a late period. At Pæstum the proportion of entablature to column is as 1 to 2·4; Ægina, 1 to 2·53; Theseum, 1 to 3 nearly.

Such are the materials of which the Greeks composed those beautiful temples, whose peculiar effect and character arise from their simplicity and harmony. These qualities are visible in the long unbroken lines which bound their forms, and the breadth, boldness, and fitness of every part. The entablature, though massive, is fully upborne by the columns, whose spreading abaci receive it, and transmit the weight downwards by the shafts, which rest on a horizontal and spreading basement,—the magnitude of every part, as before remarked, being determined by the capacity of the sustaining power. Besides graceful and elegant outline, and simple and harmonious forms, these structures exhibit a wonderful variety of light and shade, arising from the judicious contour and arrangement of mouldings, every one of which is rendered expressive. The effect is heightened by the fluting of the columns and the peculiar form of the columnar capital, with its broad square abacus, which projects a deep shadow on the bold ovolo. The play of light and shade about the insulated columns is strongly modified by the deep shadows on the walls behind them; and in front, where the inner columns appear, the effect is enchanting. For all the higher effects which architecture is capable of producing, a Greek peripteral temple of the Doric order is perhaps unrivalled.

The Grecian Ionic (Plate XI.)

Of this beautiful and graceful order it is as difficult to determine the origin as of the Doric. The explanation of Vitruvius is that the Ionian colonists, on building a temple to Diana, wished to find some new manner that was beautiful. Following the method which they had pursued with the Doric (proportioning the column according to the dimensions of a man), they imparted to this the delicacy of the female figure—in the first place, by making the diameter of the column one-eighth of its height, then by putting a base to it in twisted cords, like the sandals of a woman, and forming the capital with volutes, like the hair which hangs on both sides of her face. To crown all, he says that they chanuelled or fluted the column to resemble the folds of female garments, by which it would appear that Vitruvius did not know that the Greeks never executed the Doric order without fluting the columns. "Thus," he goes on to say, "they invented these two species of columns, imitating in the one the naked simplicity and dignity of a man, and in the other the delicacy and the ornaments of a woman."

From the recent discoveries in Assyria, however, there can be no reasonable doubt that the Greek colonists of Ionia at least obtained their idea of the Ionic capital from Nineveh. As to its earliest forms great differences of opinion exist. An extremely plausible theory, originated and ably worked out by Mr Skidmore, suggests that the delicate Ionic curls were copied from the curved ornamental wire-work of the goldsmiths. On the other hand, a recent French author has found in Sicily a rudely carved capital which is little more than a block of stone with the ends rounded off, the curve being continued, and thus forming a volute; and it is very possible that a crude idea like this might have been worked out, with some help from Assyria, into one of the many forms of the Ionic capitals.

Of this graceful and elegant style we take the proportions and peculiarities from the perfect examples of the Athenian Acropolis. This order may also be considered in three similar parts, stylobate, column, and entablature.[1] The stylobate is in three receding equal courses or steps, whose united height is from four-fifths to one diameter. The column, consisting of base, shaft, and capital, is rather more than nine diameters in height; of which the base is two-fifths of a diameter, and the capital, including the hypotrachelium, is in one case three-fourths, and in the other seven-eighths of a diameter high. As shown in the vases, it is invariably very long and slender, and without bases; but no actual example remains to us without a base. The base consists of a congeries of mouldings extending gradually from a diameter and a third to a diameter and a half, and its height is in three nearly equal parts, two equal fillets separating them. The lowest, a torus, rests on the top of the stylobate or floor of the portico, a fillet divides that from the scotia, a second fillet intervenes between the scotia and a second torus, and a third fillet bases the apophyge or escape of the shaft. The upper torus of the base is, in one example, fillet-fluted horizontally; and in the other, the same member is enriched with the guillochos. The shaft diminishes with entasis from its lower or whole diameter to above five-sixths of it immediately under the hypotrachelium. It is fluted with twenty-four flutes and alternating fillets, which follow the diminution and entasis of the column. The flutes in plan are nearly semi-ellipses, and they finish at both ends with the same curve; a fillet is in thickness nearly one-fourth the width of a flute. The difference in the height of the capital is in the length of the necking, which in one case is separated from the head of the shaft by a carved bead, and in the other by a plain fillet. Above the necking, a height of about one-third of a diameter is occupied by a congeries of three spreading or corbelling mouldings—a bead, an

[1] For explanation of terms see Plate IX figs. 5 to 8, and glossary.

ovolo, and a torus—which are all appropriately carved. On these rests the parallelogramic block, on whose faces are the volutes, and whose ends are concaved into what is technically termed a bolster to connect them. This part is about one-third of a diameter in height, and includes a rectilinear abacus, whose edges are moulded to an ovolo and carved with the egg and tongue ornament. The volutes are three-fifths of a diameter in depth, and extend in front to one diameter and a half; and they are nearly a semi-diameter apart. The volutes and the flowing lines which connect them are represented in figs. 5 and 9, Plate XI. The bolsters are fluted vertically with alternate fillets, on which are carved beads. An ornament composed of the honeysuckle with tendrils encircles the necking of the column. It must be remarked, that as the capitals are parallelogramic, and present but two similar fronts, to preserve the appearance of volutes externally on all sides, the capitals of the columns at the external angles of porticoes are differently arranged (compare figs. 15 and 16). The outer volute is bent out at an angle of 45°, and volutes are put on the end or side-front of the capital also, the outer one being the other side of the angular volute of the front. To suit the angle internally, the two volutes of the inner face are placed at right angles to each other: this is, however, at best but an awkward expedient, and need not be employed when a portico projects only one intercolumniation. All the Greek volutes are flat on the surface, except at Bassæ, where the volutes are curved.

The entablature, which is rather more than two diameters in height, is also divided into three parts,—architrave, frieze, and cornice,—which may be proportioned by dividing the whole height into five parts, four of which, as in the Doric, may be again equally divided between the architrave and frieze. The cornice, however, in the example referred to, does not occupy one-fifth of the entablature; but if it had a fillet over the upper moulding, which it appears to want, that would be just its proportion. If the architrave (fig. 8) be divided into nine parts, seven of them may be given to three equal fascias, which slightly project the one before the other, the first or lowest, which is vertical to the circumferential line of the inferior diameter, being covered by the second, and the second by the third. The remaining two-ninths form a band of mouldings corbelling a broad fillet, which separates the architrave from the frieze, these mouldings are enriched. The frieze (fig. 7), which does not project quite so much as the lowest fascia of the architrave, is, in the Athenian examples, quite plain; but it may be enriched with foliage, or made the receptacle of sculpture in low relief. In two examples (one at Selinus, and another at Agrigentum) the frieze has the Doric triglyph. The cornice (fig. 6) projects from the face of the frieze rather more than as much as its whole height, and is composed of bed-mouldings, a corona, and crown-mouldings. The first are a carved bead and carved cyma-reversa, the former of which only occupies a portion of the height of the cornice, as the planceer is cut up inwards, in the manner represented by dotted lines in the figure, to a sufficient depth for it; the crown mouldings, which consist of a carved ovolo above a carved bead, are rather more than one-fourth of the whole cornice; and the corona occupies the rest of its height, except that small portion given to the bead of the bed-mould. A fillet above the crown-mouldings, as already intimated, is certainly necessary to complete the order and receive the antefixæ, as described in the Doric, for the flank of a temple.

The pediments in the examples of Ionic are flatter than in those of the Doric, the angle made by the covering cornice with the base being, in a hexastyle, less than 14°. A vertical fillet, with a small moulding, equal in depth to the two crown-mouldings of the cornice, covers them in the pediment, in the place of the cyma-recta or ovolo used in the Doric order. The intercolumniation differs in these examples, in the one it is two diameters, and in the other three diameters and one-sixth.

A much greater variety is found in the composition of the Ionic than of the Doric order. Indeed, the examples of the Athenian Acropolis alone have neckings.[1] In all the others the shaft runs up to the corbelled mouldings which bed the block of the volutes, and the flutes finish under them. Neither have they a torus in that congeries, but a bead and ovolo alone, the latter projecting inconveniently under the pendent lines that connect the volutes, and thus the capital is not more than half a diameter in height.

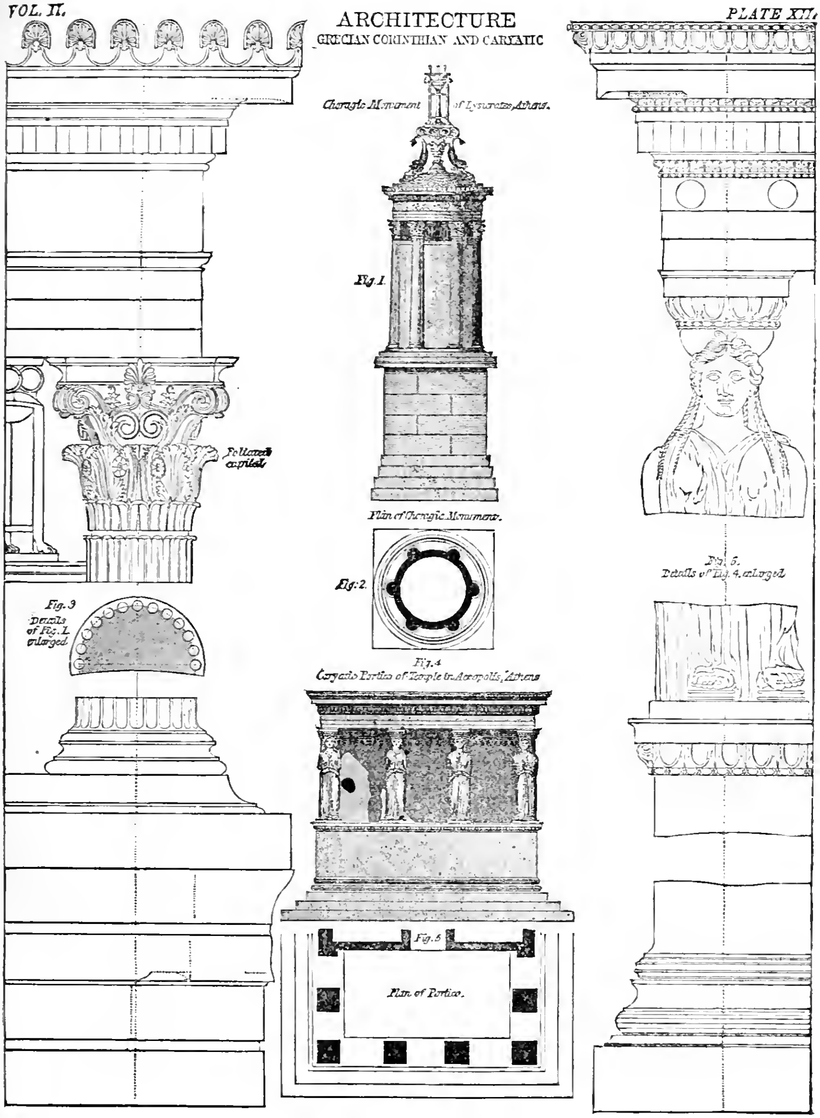
The Asiatic or the truly Ionian examples of this order are far inferior to those above referred to. Their bases are differently, and certainly less elegantly composed. They are without hypotrachelia, as may have been inferred; they want the torus in the capital; and, in most cases, instead of flowing, pendent lines, they have straight lines connecting the volutes. Their entablatures are not so finely proportioned, nor so delicately executed. The coronas want breadth, and the bed-moulds of the cornice are as much too heavy as those of Athens are perhaps too light. Indeed, upon the whole, they have more of the grossness of Roman architecture than of the delicacy and elegance of Grecian, though the Ionian examples are supposed to be the models of those of Athens. In the celebrated temple of Diana at Ephesus the columns present an almost unique example of the lower parts being sculptured. Fine specimens of these are now in the British Museum. The only instance known of sculptured columns is at Narga in Nubia.

The width of the antæ of the Ionic order is determined, as in the Doric, by the soffit of the entablature; and it will, of course, be exactly the same as, or rather less than, the inferior diameter of the column. It is slightly raised, too, from the face of the wall at the ends of which it stands. The base of the antæ is, in one of the two examples of the Acropolis, a little deeper than that of the column, having a small projecting moulding between the lower torus and the floor; and the lower torus itself is reeded. In the other example there is no difference in the form and proportion of the antæ and columnar bases, but both the tori are fluted horizontally, with beaded fillets between the flutes. The antæ cap consists of a congeries of corbelling mouldings, nearly one-third of a diameter in height. It is divided into three nearly equal parts, the lowest of which is composed of a bead and an ovolo; the second of another bead and a cyma-reversa, all carved; and the third of a plain flat cavetto, with a narrow fillet and small crowning cyma-reversa, forming an abacus (fig. 11.) The necking is like that of the capital, and is enriched in the same manner. The cap or cornice thus formed breaks round the projection of the antæ, and is continued along the wall under the entablature the whole length of the building, or till it is impeded by some other construction; and the base is continued in like manner. Attached columns have the voluted capital, but their base is that of the antæ; and it is detailed round them and along the wall to which they belong, as with the antæ. It must be remembered, however, that the attached columns in the triple temple are about one-ninth less in diameter than those which are insulated, though they are similar in other respects, and have the same entablature.

[1] A curious example of the use of the beautiful necking ornament (as at the Erechtheum) occurs in the gigantic monument in Algeria, called the tomb of the Christian Lady, whose date is supposed to be the 1st century B.C. It is evidently a rude copy of some such original as the above.

ARCHITECTURE

GRECIAN CORINTHIAN AND CARYATIC



The back of the triple temple, between the attached columns, presents one of the only two examples in Greek architecture of windows, the other being that of the temple of the Giants at Agrigentum. These are rather more than twice their width in height, and are narrower at the top than at the bottom. They rest on a broad, bold sill, which is equal in depth to two-sixths of the opening, and are surrounded externally by a congeries of mouldings, which, with a plain fascia, constitute an architrave. This architrave is one-fourth the opening in width; it diminishes with the window, and in the same proportion; and is returned above in two knees, which are made vertical to its extreme point at the base.

The Grecian Corinthian (Plate XII.)

The traditionary tale Vitruvius relates regarding the invention of the Corinthian capital (about Callimachus and the basket on the grave of the Corinthian virgin), is the only reason for the name it bears. His account of the origin of this third species of columnar composition is even more absurd than what he gives of the other orders. He says that it was arranged "to represent the delicacy of a young girl whose age renders her figure more pleasing and more susceptible of ornaments which may enhance her natural beauty." With much more reason might the Doric be called the Corinthian order; for, as previously stated, the oldest existing example of that style is at Corinth; whereas there is nothing, either in ruins or authentic records, to prove that the latter was ever known in that city. Columns with foliated capitals are not of very early date in Greece; earlier examples exist in Asia Minor, and foliage adorns the capitals of columns in some of the Pharaonic monuments of Egypt. In the Assyrian sculptures, however, the Corinthian capital is clearly shown. The interior of the temple of Apollo Didymæus, at Miletus in Ionia, exhibits the earliest example of the acanthus leaf arranged round the drum of a capital in a single row, surmounted by the favourite honeysuckle; but that edifice was constructed about a century before Callimachus is understood to have lived. The only perfect columnar example in Greece itself of this species of foliated capital is of later date than, and is a great improvement on, that of Miletus; it is the beautiful little structure called the choragic monument of Lysicrates at Athens. (Plate XII. figs. 1, 2, 3.) Specimens of square or antæ capitals enriched with foliage are less uncommon in Greece than of circular or columnar capitals; but they are almost invariably found to have belonged to the interior of buildings, and not to have been used externally. In considering Greek architecture, it is necessary to bear in mind that it ceases almost immediately after the subjection of Greece to the Roman power; for though there are many edifices in that country in the style of columnar arrangement of which we are now speaking besides those referred to, they belong to Roman, not to Greek architecture. The earliest of them, perhaps, and certainly the least influenced by Roman taste, is the structure called the tower of the Winds, or of Andronicus Cyrrhestes, at Athens. The Agora, or Doric portico, as it is sometimes designated, in the same city, is a spurious example of Greek Doric, evidently executed under the Roman domination.

The importance which the Greeks attached to a graduated stylobate, and the necessity of giving it a relevant proportion in a columnar ordinance, are shown in the building above mentioned, which is the only example of this order of Grecian origin remaining to us. Unlike the Doric and Ionic in its application, this order is represented in a small circular structure, resting on a lofty square basement; and yet, like those orders, it has a stylobate in receding courses (see Plate XII. fig. 3), and in plan, too, corresponding with the arrangement of the columns, and not with that of the substructure,—this furnishing further proof that the stylobate was considered a part of the columnar ordinance. The Corinthian column is ten diameters in height. The base is composed of a torus and fillet; a scotia and another similar fillet, rather less than the former; and a second torus or reversed ovolo, on which rests a third fillet basing the apophyge of the shaft. The shaft diminishes with entasis to five-sixths of its diameter at the hypotrachelium, and, like that of the Ionic order, has twenty-four flutes and fillets. The flutes are semi-ellipses, so deep as nearly to approach semicircles, terminating at the head in leaves, to which the fillets are stalks. The fillets are rather more than one-fourth the width of the flutes. The hypotrachelium is a simple channel or groove immediately under the capital. The capital itself is rather more than $1\frac{1}{3}$ diameters in height, its core is a perfect cylinder, in bulk rather less than the superior diameter of the shaft. This is banded by a row of water-leaves, whose profile is a flat cavetto, one-sixth of the whole height, and another of leaves of the acanthus, with flowered buttons attaching them to the cylinder. The latter have the contour of a cyma-recta, and occupy one-third of the whole capital. Rather more than another third is occupied by calices and tendrils, which latter support a honeysuckle against the middle of the abacus. This member is in plan a square whose angles are cut off at 45°, and whose sides are deeply concaved. In profile it consists of a narrow fillet, an elliptical cavetto or reversed scotia, and another fillet surmounted by a small ovolo, or rather a moulding whose profile is the quadrant of an ellipse. In the entablature (which is $2\frac{2}{7}$ diameters in height), the architrave is divided, like that of the Ionic order, into three equal fascias, which are not perpendicular, but incline inwards, so that their lower angles are all in the same vertical line; this impends the surface of the shaft about one-third of the height from the base. The frieze is one plain band, slightly inclining inwards like the fascias of the architraves, and slightly projected beyond them. The cornice consists of a deep congeries of bed-mouldings, and a corona, with the accustomed small crown-mouldings and fillet. As in the Ionic cornice, additional height is given to the bed-moulds by undercutting the planceer. The cornice is surmounted by a cut fascia supporting honeysuckle antefixæ, which may indeed be taken as a part of the order, as the solitary example in question presents it.

Of Corinthian antæ we have no examples, nor indeed have we of insulated columns; but as we find in the Ionic examples quoted that the attached columns are less in proportion to the entablature than those which are insulated, we may conclude that it would be the same with this,—thus reducing the entablature to two diameters, the ordinary average of that part in Greek columnar architecture.

The Caryatides, or Caryatic Order (Plate XII.)

Besides the three species of columnar arrangement enumerated above, the Greeks employed another in which statues of women occupied the place of columns. The origin of this order is furnished by Vitruvius in a story which is as usual totally unsupported by history or analogy. Nevertheless it has fixed the nomenclature, such figures being called Caryatides, and the arrangement the Caryatic order. The use of representations of human and other figures with or instead of columns is, however, common in Egypt and India; and to the former the Greeks were doubtless indebted for the idea, though they appear to have restricted its application to human female figures. Mr Gwilt infers from various facts connected with the worship of Diana Caryatis, "that the statues called Caryatides were originally applied to or used about the temples of Diana; and instead of representing captives or persons in a state of ignominy (according to the Vitruvian story), were in fact nothing more than the figures of the virgins who celebrated the worship of that goddess."

Of these Caryatides there is but one existing example. It is the third portion of the triple temple in the Athenian Acropolis, and is a projection from the flank of the principal Ionic structure, formed by a stereobatic dado raised on the stylobate and antæ-base mouldings, with a sur-base consisting of a carved bead and carved ovolo covered by a broad listel, with a narrow projecting fillet above it. On this rests a square plinth, supporting a draped female figure, on the head of which there is imposed a circular moulded block, with a deep rectangular abacus, two-thirds of whose face is vertical, and the other third is a cavetto fillet, and small cyma-reversa. The stereobate, including the moulded base of the temple, is about three-fourths the height of the statue pillar with its base and capital. The entablature is rather less than two-fifths of the same, but it consists of architrave and cornice alone, between which parts the height is nearly equally divided. Details will be understood by reference to Plate XII. figs. 4, 5, 6. This Caryatidean portico displays very clearly the arrangement of the ceiling, with its coffers or cassoons. Internally the architrave is plain two-thirds of its height; of the remaining third rather more than one-half is a plain, slightly projected fascia; the other half is occupied by a carved bead and ovolo. In the absence of a frieze the ceiling rests on this, and is divided by carved beads into panels, which are deeply coffered, and diminished by three horizontal moulded fascias.

Of Grecian Mouldings and Ornaments.

Mouldings. Greek architecture is distinguished for nothing more than for the grace and beauty of its mouldings; and it may be remarked of them generally that they are eccentric, and not regular curves. (Plate XIII.) They must be drawn, for they cannot be described or struck; so that though they may be called circular, or elliptical, it is seldom that they are really so, and if they are, it is evidently the result of chance, and not of design. Hence all attempts to give rules for striking mouldings are worse than useless; the hand alone, directed by good taste, can adapt them to their purpose, and give them the spirit and feeling which render them effective and pleasing.

The leading outline of Greek moulding is the gracefully flowing cyma. This will, indeed, be found to enter into the composition of almost everything that diverges from a right line; and even combinations of mouldings are frequently made with this tendency. It is concave above and convex below, or the reverse; and though a long and but slightly flected line appears to connect two quickly-curving ends, it will always be found that the convexity and the concavity are in exactly the same curve, so that if the moulded surface were reversed, and the one made to assume the place, it would also have the appearance, of the other, and the effect would be the same. It is, in fact, the Hogarthian line of beauty; and it is not a little singular that Hogarth, in his well-known *Analysis of Beauty*, although he did not know, and indeed could not have known, the contours of Greek architectural mouldings, has given the principle of them, and, under his line of beauty, has described many of the finest Greek forms. The Roman and Italian mouldings were called Greek in his day, and he assumed them to be so; but they evidently do not agree with his theory, whereas, in principle, the now well-known Greek forms do most completely.

The cyma-recta is generally found to be more upright and less deeply flected than the cyma-reversa; it is almost always the profile of enrichments on flat surfaces, of foliage, of the covering moulding of pediments, of the undercut or hooked mouldings in antæ caps, the overhanging not affecting the general principle; and it pervades, as we have said, flected architectural lines generally, whether horizontal or vertical. The cyma-reversa has all the variety of inflection that its opposite possesses, but the line connecting its two ends is, for the most part, more horizontal, and its curves are deeper. It pervades many architectural combinations, but is most singularly evinced in the composition of the Greek Doric capital, which is a perfect cyma-reversa, with the ends slightly but sharply flected, as it flows out of the shaft below, and turns in under the abacus above. This may not be obvious, from the annulets dividing the cyma into an ovolo and a cavetto, but the principle is clear.[1] The cyma is the governing outline in the congeries of mouldings in bases also, as may be noticed in the Ionic and Corinthian examples quoted and referred to.

An ovolo is but the upper half of a cyma-reversa, even when it is used as a distinct moulding, and unconnected with the waving form. The name expresses its apparent rather than its real tendency; for its contour is not that of an egg in any section, though the ornament which is carved on it, when used as a running moulding, is formed like an egg; and from that the moulding was named.

The upper torus of a base forms, with the escape or apophyge of the shaft, a perfect cyma, and the scotia and lower torus do the same; so that the torus and scotia are referable to the same principle when in composition, and they are not found together except in the combination referred to.

The bead is an independent moulding, varying in contour; but it is generally the larger segment of a circle. It is used, however, sometimes to mask the waving form, and sometimes to separate it.

The cavetto, or simple hollow, is part of a cyma also, as has been shown; but it is also applied independently to obviate a sharp angle, or to take from the formality of a vertical line, as in the abaci of Ionic antæ caps. Its form, nevertheless, is not the segment of a circle, for the upper part of a cavetto is the most flected, and it falls below almost into a straight line.

There is a hooked moulding common in Greek architecture, particularly in the Doric antæ caps, which is technically called the hawk's-beak. It is a combination of curves which cannot be described in words; but it has been already referred to in speaking of the cyma-recta, which is brought into its composition. This hawk's beak is a completely Gothic moulding, and throws a very bold, clear shadow. It is used generally to the antæ; and the fact that these were for the most part under the shadow of the peristyle, furnishes good reason for the employment of such a moulding.

The cyma-recta is never found carved, nor sunk within itself; but it sometimes has the honeysuckle, or some other ornament of the kind, wrought on it in relief, particularly when used as the covering moulding—the cymatium—or a pediment. The enrichment of the cyma-reversa consists of a contrasted repetition of its own contour meeting in a broad point below, and joining by a circular line above, making a sort of tongued or leafed ornament, whose surface is inflected horizontally also. Between the leaves a dart-formed tongue is wrought, extending from the circular flexure above to the bottom of the moulding, whose contour it takes in front alone. As this would not mitre or join well on the angles of the cyma, a honeysuckle is

[1] The presence of the cyma in the Doric capital was, we believe, first pointed out by Mr T. L. Donaldson, in a supplementary volume to Stuart's *Athens*.

gracefully introduced in the manner shown in Plate XIII. This enrichment is not wrought in relief on the moulding, but is carved into it, so that the surfaces of the parts of the ornament alone retain the full outline of the cyma. The ovolo is enriched with what is called the egg and dart ornament. This will be best understood by reference to the plate. Its angles also are made with a honeysuckle, and the inflections are made in the moulding itself. The torus is sometimes enriched with the interlaced ornament called the guillochos; this, too, is cut into the moulding itself. We have no Greek example of an enriched scotia, and from its form and position, which, to be effective, must be below the eye, it hardly seems susceptible of ornament which could operate beneficially. The bead is carved in spheres or slightly prolate spheroids, with two thin rings or buttons, dilated at their axes, placed vertically between them. A cavetto is not enriched at all, nor is the hawk's beak, except by painting, which does not appear to have been an uncommon mode of enriching mouldings among the Greeks; that is, the ornament was painted on the moulded surface instead of being carved into it. Fascias are also found enriched by painted running ornaments, such as the fret or meander, the honeysuckle, and the lotus. Sometimes plain colour was given to a member, to heighten the effect it was intended to produce. Ornaments were also painted and gilt on the coffered panels of ceilings.

Sculptured ornaments.

The few examples which exist of sculptured ornament on straight surfaces exhibit varieties of nearly the same combinations as those last mentioned,—the honeysuckle, with the lotus, and sometimes a variety of itself, on scrolls, either throwing out tendrils, or plain. This is found on the necking of the Ionic columns of the Athenian Acropolis, and on those of their antæ, continuing along under the congeries of mouldings, as previously described. The varieties of foliage used in the enrichments of Greek architecture are few, and will be found generally exemplified in the Corinthian capital of the choragic monument of Lysicrates, and in the rich acroteral pedestal or stem of the same edifice, than which we possess no more elaborate specimen of foliated enrichment of the Greek school. There exist many specimens of architectural ornament on vases and fragments, in marble and terra-cotta, in which human figures, both male and female, are composed, with a greater variety of foliage than is generally found in Greek architectural works; and many of the beautiful marble and bronze utensils discovered in Herculaneum and Pompeii have enrichments obviously of Greek origin, from which, as well as from the specimens of ornament on positive architectural monuments, we may judge of their productions generally, as well as acquire or imbibe something of the fine taste which originated them. It will be remarked at once that Greek ornamentation is quite conventional, and that the plain scroll forms its main feature. The leaf-work is clasped round it, and helps to fill up the surface, and pleasingly vary the outline, but the scroll is prominent throughout. Then there is a peculiarity in the mode of carving the ornamentation. The scroll is not rounded off, as in the Roman, like the branch of a tree, but stands squarely and sharply out from the surface, so as to throw a well-defined sharp shadow. So with the foliage, whose leaves also, in place of having the rounded section used by the Romans, are cut sharply either with a square or triangular section, giving again a strong contrast of light and shade.

It may be inferred from some existing edifices, particularly the choragic monuments, that the Doric columnar style was not used by the Greeks except for the temples of the gods and some of their accessories. But whether this arose—if the feeling really did exist—from the sanctity of its character, in consequence of that appropriation, or from the difficulty of moulding it to general purposes, cannot be determined. It is very certain, however, that the few structures which do exist of Greek origin, not of a religious character, are either Ionic or Corinthian, or a mixture of one of them with some of the features of the Doric; and in all Greece and the Grecian colonies, except Ionia, there are very few examples of religious edifices not of the Doric order, and none which are of the Corinthian.

Regularity of the Doric style.

Like the architecture of Egypt, that of Greece is known to us principally by means of its sacred monuments, and from them is deduced almost all we know of its principles. The Doric temples of the Greeks are uniform in plan, and differ only in arrangement and proportion, according to their size; for every part depends on the same modulus. It has been said that if the dimensions of a single column, and the proportion the entablature should bear to it, were given to two individuals acquainted with the style, with directions to compose a hexastyle peripteral temple, or one of any other description, they would produce designs exactly similar in size, arrangement, features, and general proportions, differing only, if at all, in the relative proportions of minor parts, and slightly, perhaps, in the contour of some of the mouldings. This can only be the case with the Doric, and it arises from the intercolumniation being determined by the arrangement of the frieze with triglyphs and metopes; the frieze bearing a certain proportion in the entablature to the diameter of the column, and so on, in such a manner that the most perfect harmony is preserved between all the parts. Thus (Plate IX. fig. 1) the column is so many of its diameters in height; it diminishes gradually from the base upwards, with a slightly convexed tendency or swelling downwards; and is superimposed by a capital proportioned to it, and coming within its height. The entablature is so many diameters high also, and is divided, according to slightly varying proportions, into three parts —architrave, frieze, and cornice. A triglyph bearing a certain proportion to the diameter of the column is drawn immediately over its centre; the metope is then set off equal to the height of the frieze; another triglyph is drawn, which hangs over the void; then a metope as before; and a second triglyph, the centre of which is the central line for another column; and so on to the number required, which, in a front, will be four, six, eight, or ten columns, as the case may be, the temple being tetrastyle, hexastyle, octastyle, or decastyle; and on the flanks twice the number of those on the front and one more, counting the columns at the angles both ways. Thus, if the rules be strictly followed, a hexastyle temple will have thirteen columns on each flank, an octastyle seventeen, and so on. It must be observed, however, that to ease the columns at the angles, they are not placed so that the triglyph over them shall impend their centre as the others, but are set in towards the next columns, so far that a line let fall from the outer edge of the triglyph will touch the circumferential line of the column at the base, or at its greatest diameter. It has been generally thought that the object in this disposition was to bring the triglyph to the extreme angle, to obviate the necessity of a half-metope there; and many imitators have puzzled themselves to no avail to effect it without contracting the intercolumniation or elongating the first metope; though it is perfectly obvious that the intention of the Greek architects was to ease the columns in those important situations of a part of their burden, and for no such purpose as Vitruvius and his disciples have thought. Indeed, this has been a problem to the whole school, which their master proposed, and which they have settled only by putting a half-metope beyond the outer triglyph, thus preserving the intercolumniation equal, but rendering the quoins more infirm, or perhaps less stable than the Greek architects judiciously thought they should be. Besides contracting the intercolumniation, the Greeks also made the corner columns a little larger than the rest, thus counteracting in every way the danger that might accrue to them, or to the structure through them, from their exposed and partly unconnected situation. The graduated pyramidal stylobate on which the structure rests also bears a certain proportion to the standard which is measure of all the rest; and so every part is determined by the capacity of the sustaining power.[1] Though the Doric order thus possesses, as it were, a self-proportioning power, which will secure harmony in its composition under any circumstances, yet skill and taste in the architect are necessary to determine, in every instance, the number of diameters the column shall have in height, and to assign according to that the height of the entablature. According to Vitruvius the colonnades were spaced out according to one or other of the following arrangements of the intercolumniations:—

Pycnostyle,	1½ diameters	apart	and 10	high.
Systyle,	2 ,,	,,	9½	,,
Eustyle,	2¼ ,,	,,	about 8½	,,
Diastyle,	3 ,,	,,	8½	,,
Aræostyle,	4 ,,	,,	8	,,

But these rules, like many others of this author, seem to have been imaginary.

Columnar arrangement of temples.

The temples are described, according to their external arrangement, as being either *in antis* (*i.e.*, with two columns between two antæ), prostyle (with columns in front), amphiprostyle (with columns both in front and rear), peripteral (with a single row of columns at flanks as well as at ends), dipteral (with a double row of columns at flanks), or pseudo-dipteral (in which the inner range of columns in the peripteral is omitted). The columnar arrangement *in antis* is not common in Greek architecture, though there are examples of it, generally of the Doric order. The inner porticoes, or pronaoi, of peripteral temples are, for the most part, placed *in antis*, as may be seen by reference to the examples in which columns stand between the antæ. The Ionic temples of Athens are the principal examples of the simple prostyle. They may be called apteral, if it be necessary to distinguish them from peripteral, as the latter are prostylar; but the former term alone is sufficient. Neither does Greek architecture present more than one example, and that is at Athens also, of an amphiprostyle, except in the same peripteral structures, which are also amphiprostylar. Almost all the Doric temples are peripteral, and being peripteral, they are, as a matter of course, amphiprostylar, as has been just remarked; so that the former term alone is used in describing an edifice of that kind, with the numeral which expresses the number of columns in each of its prostyles. There are but two known examples of Greek antiquity of a pseudo-peripteral structure—the gigantic fane of Jupiter Olympius at Agrigentum, and the nine-columned edifice at Pæstum. The former is not even prostyle, for the columns on its fronts are attached, as well as those on its flanks. The dipteral arrangement is found at Selinus, in an octastyle temple; and in some cases the porticoes of peripteral temples have a pseudo-dipteral projection, though no perfect example of the pseudo-dipteral exists.

The Doric order was never used by the Greeks in mere prostyles; consequently there is no Doric temple of the tetrastyle arrangement, for it is incompatible with the peripteral, the tetrastyle examples which do exist being all Ionic. Athens itself, containing a Doric tetraprostyle, may seem to contradict this; but in speaking of Greek architecture, we exclude all the examples, even in Greece itself, which were executed under the Roman dominion, for they bear the Roman impress; and among these is the portico referred to. With very few exceptions, all the Doric temples of the Greeks are hexastyle. Their queen, however, the unmatched Parthenon, is octastyle; and the pseudo-peripteral fane of Jupiter Olympius at Agrigentum, just referred to, presents the singular arrangement, heptastyle. The misshapen monument called the Basilica, at Pæstum, the Thersites of its style, has a front of nine columns, or an enneastyle arrangement. The temples of Jupiter Olympius at Athens, and of Apollo at Branchidæ, had each a front of ten columns.

It may be here remarked in support of the opinion we have given as to the authority of Vitruvius, that, according to him, peripteral temples have on each flank twice the number of intercolumniations they have in front,—thus giving to a hexastyle eleven, to an octastyle fifteen columns, and so on,—whereas in the Greek temples this is never the case, for they always have more. The best examples have two, some have only one, but many have three, and in one instance there are four, more intercolumniations in flank than in front. The famous temple at Ephesus, recently disinterred by Mr Wood, has seven intercolumniations in front, and nineteen on the flanks. Again, he limits the internal hypæthral arrangement to those structures which are externally decastyle and dipteral, though an example, he says, existed in Greece of an octastyle hypæthros, and that was a Roman structure. Now the Parthenon is an octastyle hypæthros; but all the other hypæthral temples, both in Greece and her colonies, are hexastyles, except, perhaps, the octastyle-dipteral at Selinus, and there is no evidence that the Greeks ever constructed a decastyle-dipteral temple, except that of Apollo Didymæus at Branchidæ.

A Greek temple, whose columnar arrangement is simply *in antis*, whether distyle or tetrastyle, consists of pronaos and naos or cella. A tetraprostyle may have behind it a pronaos and naos. An amphiprostyle has, in addition to the preceding, a posticum, but is not understood to have a second entrance. The porticoes of a peripteral temple are distinguished as the porticus and posticum, and the lateral ambulatories are incorrectly called peristyles. It may, indeed, be here suggested, that as the admixture of Latin with Greek terms in the description of a Grecian edifice cannot be approved of, it would, perhaps, be better to apply the term *stoa* to the colonnaded platform or ambitus altogether, and distinguish the various parts of it by the addition of English adjectives; or the common term portico would be quite as well with front, back, and side, or lateral, prefixed, as the case may be. Within the back and front stoas or porticoes, then, a peripteral temple has similar arrangements *in antis*, which are relatively termed the pronaos and opisthodomus, with an entrance only from the former; unless there should exist, as there does in the Parthenon, a room or chamber within the opisthodomus, supposed to be the treasury, in which case a door opens into it from the latter. Besides these, a Greek temple consists only of a cell in those which are cleithral, and of a naos, which is divided into nave and aisles, to use modern ecclesiastical terms, in an hypæthral temple.

In comparing the Greek temple with the Egyptian, a marked difference at once appears. The cella is the nucleus of both. But whereas the Egyptian was almost hidden within a series of chambers for the priests, and surrounded by enormous enclosed courts, the Greek was made the one prominent object, and the subject of the highest efforts of art.

[1] We cannot discover that the elevation of the pediment depended so immediately on the common standard, though in the best examples the tympanum will be found to be about one diameter and a half in height.

Nothing was allowed to interfere with it or to abate its predominance. The tympan was the place in which the highest efforts of the sculptor were placed, the purest example of it being at the Parthenon. At Ægina the figures were entirely detached. Above the pediment at the top, and at the sides, were some very beautiful ornaments—the acroteria. These were in so prominent a position, and so delicately carved, that very few remains of them are left to us. The roofs were covered with thin slabs, or tiles, of marble, and the ends of the ribs, which covered their joints, were ornamented with antefixæ, forming a graceful finish to the flanks. These were mostly of marble, but at Ægina they were of terra-cotta. Further, in order to discharge the water from the gutters, were lions' heads, the original of our gurgoyles. The gutters themselves were made on the top member of the cornice. It is singular that we have no accurate description of the interior of a temple, nor any information as to how it was ceiled or lighted. We know that the cella had often a row of columns round it internally, and that upon this row was a second, as at the temples of Ceres at Eleusis, Minerva at Tegea, Neptune at Pæstum, and Jupiter at Ægina. At the temple of the Giants at Agrigentum a row of figures took the place of the upper columns. We may fairly suppose, then, that the first row supported a gallery much as in our Triforia. But as to the roof there is more difficulty. The span would be too great for flat marble beams, and would have a very poor and depressing effect. To obviate this difficulty Mr Fawkener suggests that the ceilings were arched, and a medal which shows the temple of Juno at Samos certainly appears to favour this theory. But another difficulty remains, viz., as to the light, for there were no windows; and the only light, therefore, if no other access for it were made, would have been through the doorway itself, deeply buried behind a massive portico. Vitruvius alludes to this in his third book, where he describes a hypæthral temple as being "*sine tecto et sub divo.*" But he states himself that this arrangement was rare, and if the cella was really in any case open to the sky, one can scarcely imagine how the delicate statues of ivory and gold could have been protected from the weather. At Bassæ some remains of roof tiles have been found, the centre part of which were open, and might thus have formed small openings for light. But the difficulty as to the statues remains. Mr Fergusson's solution of the problem is very ingenious, and so satisfactory that it seems to require only some reference to his arrangement in any of the old sculptures or writers to make it generally received. He supposes that the inner columns supported a sort of clerestory, formed by a channel on each side along the roof. This would give an excellent light, and the statues could easily be protected. This theory does not fulfil Vitruvius's description "*sine tecto,*" but he is generally so inaccurate in his references to Greek work that this objection does not seem to be very formidable.

According to the rules of Vitruvius, all temples should face east and west, and the door should be to the west; but in reality the doors in Ionia, Attica, and Sicily were to the east. The temple at Bassæ faces north and south, but it has a side door also. The temple was usually approached by a flight of steps, of an uneven number, so that the worshipper might place his right foot on the first step, and again on the temple floor. The ceilings of the porticoes and colonnades were formed by great beams of marble, and the spaces of the intercolumns were thus limited. This appears to be the reason for the closed colonnade of the temple of the Giants at Agrigentum, as the spaces between the columns, if open, as usual, would have been too wide to be spanned by a flat beam.

Propylæa.

The only pure Greek architectural works besides temples that remain to us, and of which we have certain information, are propylæa, choragic monuments, and theatres. The propylæum, or propylæa, as applied to the Acropolis of Athens, is the entrance or gateway through the wall of the peribolus. It consists of a Doric hexaprostyle portico internally, with a very singular arrangement of its columns, the central intercolumniation being ditriglyph. This was done, probably, to allow a certain procession to pass, which would have been incommoded by a narrower space. Within the portico there is a deep recess, similar to the pronaos in a temple, but without columns *in antis*; a wall pierced with five doorways, corresponding to the intercolumniations of the portico, close to the entrance; and beyond it is a vestibule, divided into three parts by two rows of three Ionic columns, and forming an outer portico, fronted externally by a hexaprostyle exactly similar to that on the outside. Right and left of it, and setting out about one intercolumniation of the portico from its end columns, at right angles, are two small triastyle porticoes *in antis*, with chambers behind them. These have been called temples, but most probably they were nothing more than porters' lodges or guard-houses. The whole structure, though extremely elegant and possessing many beauties, is not a good architectural composition: the unequal intercolumniation detracts from its simplicity and harmony. The use of Ionic columns in a Doric ordinance is equally objectionable; and their elevation from the floor of the portico on insulated pedestals is even worse, though their intention is obvious; and without raising them, the ceiling might have been too low, or they must have been made taller. The uneven style of the small temples or lodges is not pleasing, even though they be taken as flank and not as front compositions; and, moreover, their entablature abuts indefinitely against the walls of the larger structure, both internally and externally, to the total destruction of the harmony of the general composition. Indeed, the unequal heights of the entablature of the greater ordinance involves a fault which would require more than all the beauties of detail and harmony of proportion to countervail, if it were not impossible to embrace them in one view.

Choragic monuments.

The choragic monument of Lysicrates (or Lantern of Demosthenes), at Athens (Plate XII.), is a small structure, consisting of an elegant quadrangular basement or podium, which is more than two-fifths of the whole height, surmounted by a cyclostyle of six Corinthian columns, attached to, and projecting rather more than one-half from a wall which perfects the cylinder up to the top of their shafts, where it forms a stand for tripods the height of the capital. A characteristic entablature rests on the columns, and receives a tholus or dome, which is richly ornamented, and terminates in a foliated and heliced acroterium. To this Stuart has added dolphins as supporters, and has placed on the summit a tripod, which was the prize in the choragic festival; thus completing, perhaps, the most beautiful composition in its style ever executed. In Vitruvian language, the arrangement of this edifice would be called monopteral; but it is more correctly cyclostylar, or, perhaps, because of the wall or core, it may be termed a pseudo or attached cyclostyle. The basement of this monument is eminently bold and simple, admirably proportioned to the rest of the structure, and harmonising perfectly with it. The columnar ordinance is the only perfect specimen of the style in existence of pure Greek origin. It has never been surpassed, and is, perhaps, unequalled. The most exquisite harmony reigns throughout its composition; it is simple without being poor, and rich without being meretricious.

Totally different in style and arrangement, and far inferior in merit, is the choragic monument of Thrasyllus

It bears, however, the impress of the Grecian mind. This composition is merely a front to a cave, consisting of three pilasters, proportioned and moulded like Doric antæ, and supporting an entablature similar in style, but too shallow to harmonise with them. Above the entablature there is an attic or parapet, divided into three compartments horizontally. The two external form tablets, with a cornice or impost on them; and the central is composed of three receding courses, on the summit of which is seated a draped human figure, whether male or female, in its mutilated state, is not determinable. The entablature has laurel wreaths instead of triglyphs in the frieze, and it would appear as if the absence of the triglyph had deranged the whole composition. The two outer pilasters are of good proportion, and the architrave is well proportioned to them; but the frieze and cornice are both too narrow, and the spaces between the pilasters, equivalent to intercolumniations, are too wide. The third pilaster, itself inharmonious, is absurdly narrow, and, standing immediately under the statue, evidently to support it, its meagreness is the more obvious and striking. In spite of all this, the general outline of the structure is simple and pleasing; the detail is elegant, and the execution spirited and effective. This little monument is, however, a proof that the Greeks were not at all times so excellent in architectural compositions as in the self-composing Doric temples, and in the choragic monument of Lysicrates; and to this evidence may be added that of the triple temple in the Acropolis of Athens, already described.

The Erechtheum. In concluding this notice as to temples, we must now allude to one example, very beautiful in itself, but an exception to all rules—the Erechtheum at Athens. It consists of an Ionic hexaprostyle in front (Plate XI. fig. 1), resting on a bold, continuous, and well-proportioned stylobate, and forming the entrance to a parallelogramic cella, but, from all that has yet been discovered, without a pronaos *in antis.* The back front consists of four columns, like those of the portico, attached *in antis;* and the flanks are broad and bold, crowned by the well-proportioned and chaste entablature, with the enriched congeries of mouldings and running ornament of the antæ under it. In the absence of a pronaos to give depth to the portico, the composition was defective, but otherwise simple and harmonious. It was enlarged by the attachment of a tetraprostyle to one of its sides, Ionic certainly, like that in front, but different both in manner and in size; beautiful in itself, but a blot on the main building, with which it harmonises in no one particular, for the apex of its pediment only reaches to the cornice of the other. In a similar situation, against the other side, is attached a similar arrangement of Caryatides, a tetraprostyle of female figures raised on a lofty basement, and yet not reaching to the entablature of the main building—according in no one particular either with it or with the portico on the other side, and altogether forming one of the most heterogeneous compositions to be found in ancient art.

Tombs. TOMBS.—These, the grandest structures next to the temples in Egypt, present little worthy of notice in Greece proper; but in the colonies there are several of considerable importance. The grandest are in Caria and Lycia, to some of which, constructed much after the ancient outlines of the Lycian, &c., reference has already been made. The most singular of the pure Greek tombs are cut in the face of the solid rock, not in the forms of the ancient rock-cut tombs, but much resembling those of the temple.

The rock-cut tombs, as, *e.g.*, at Telmissus (Lycia), usually have a portico of columns *in antis*, with one or more chambers behind. In one example these are about 12 feet by 9 feet, and 6 feet high.

Most of the columns are Ionic, few being Doric. In one case, the whole tomb, which is 18 feet 6 inches deep, has been quite detached, the whole excavation being 26 feet deep from the face of the rock. Many of these tombs present curious examples of wooden details imitated in stone, *e.g.*, the doors are often exactly like those of wood, the panels, nails, knockers, &c., being copied in stone.

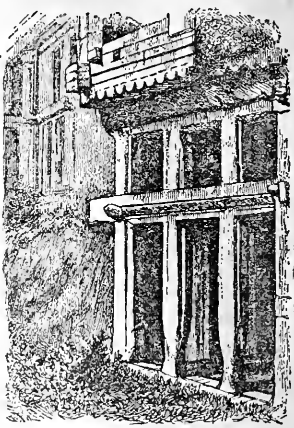

FIG. 44.—Rock Tomb at Myra, Lycia.[1]

Of a totally different class is a tomb at Cnidus, in Caria, discovered by Mr C. T. Newton. It consists of a square, low basement resting on four steps, and carrying four engaged Doric columns, with a cornice over the whole, being about 31 feet square on the basement. Above the cornice are gradini, forming a sort of pyramid of steps, having at the summit a lion, now in the British Museum. "Inside was a beehive-shaped chamber, with vaulting similar to that of the treasury of Atreus at Mycene, and with eleven smaller cells radiating from its circumference" (Newton). Its supposed date is about 396 B. C.

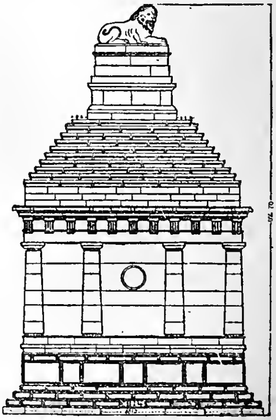

FIG. 45.—Lion Tomb at Cnidus, Caria.

More beautiful in detail is the tomb known as the Trophy, discovered by Sir C. Fellows, at Xanthus. It consists of a peristyle of fourteen Ionic columns, standing on a high basement about 33 feet by 22, which has, to all appearance, no access to it. In the centre, behind the columns, is a cella apparently solid also. The date usually given to this is about 540. But the edifice seems to be somewhat too refined in detail for this time, and another date assigned to it, viz., about 385, appears to be more likely. This would be about half-way, in point of time, between the Erechtheum and the temple at Priene.

More curious, though less elegant, is another tomb at Mylasa, in Caria, which has a high, square basement with

[1] Figs. 44 and 45 are taken from Newton's *Travels and Discoveries in the Levant*, by kind permission of the author.

a chamber in it. Over this, on each face, are two columns *in antis*, with entablature, the space between the columns being quite clear. Over the cornice are placed great stone beams, anglewise; on these, others, again, crosswise; so that the bearing is rapidly diminished, and a rough sort of dome formed, resembling those so often found in India. But of all Greek tombs the grandest was that of Mausolus, at Halicarnassus, in Caria, one of the seven wonders of the ancient world, which has given its name to all succeeding great tombs. Its date is about 352 B.C., Mausolus having died in 353. It was erect until the 10th century. Since then it has been so utterly ruined that there was doubt as to its actual site. This was indicated by Professor Donaldson; and in 1857, Mr Newton discovered the actual remains. "It consisted of a lofty basement, on which stood an oblong Ionic edifice surrounded by thirty-six Ionic columns, and surmounted by a pyramid of twenty-four steps. The whole structure, 140 feet in height, was crowned by a chariot group in white marble, on which, probably, stood Mausolus himself" (Newton). The size of the basement was 114 feet by 92. A considerable number of the fragments are now in the British Museum. The name of the architect was Pythius, and the sculpture, with which the edifice was richly adorned, was executed by four celebrated sculptors, of whom we may especially particularise Scopas, as he was also the architect of the celebrated temple of Tegea.

Theatres.

THEATRES.—The Greek theatre deserves a short notice. It was entirely different from ours, having neither pit, boxes, nor roof, except the usual velarium, as a protection from the sun. Its plan was somewhat more than a semicircle, having seats cut out of the side of some hill convenient for the purpose. Round the top was a colonnade, and at the back of the stage was the scena. This and the colonnade combined in an artistic way, must have formed a very effective composition. At first the theatres were of wood; the first of stone, at Athens, having been built, it is said, about the middle of the 4th century. Vitruvius makes some very singular statements as to the acoustic details of the theatres, but they have not been verified, and are not, in fact, quite understood. The theatres at Argos and Ephesus were 450 and 600 feet in diameter respectively, whereas Covent Garden Theatre, London, including the corridors, is only 100 feet.

HOUSES, &c.—No remains exist of the domestic structures of the Greeks. It may be taken for granted that the houses were less extensive than those of the Romans, as they were a poorer and less luxurious people, but the exquisite beauty of form and decoration, which pervades every article of Greek origin, whether coin, medallion, vase, implement of war or husbandry, or even the meanest article of domestic or personal use, is evidence of the fine taste with which their mansions must have been furnished.

Fortifications.

FORTIFICATIONS.—We have large remains of fortifications in Lycia, though few in Greece proper. They are not so picturesque as the mediæval, nor, we may say, as the Assyrian. They were massively built of masonry, with square towers at intervals, furnished sometimes with a pediment, sometimes with battlements. The doors and windows on the upper floor are still found at Alinda, in Caria. The Greek shield was often sculptured as hung on the walls. A bas-relief from Pinara, in Lycia, gives a complete sketch of the walls, with circular-topped battlements, a postern gate, and various openings, all square-headed; and a door is shown panelled, like our doors.

Building materials.

In the construction of their edifices the Greeks seldom, if ever, had recourse to foreign materials—the stone used in their temples being almost invariably from the nearest convenient quarries which supplied it of sufficiently good quality. The structures of Athens are built of marble, from the quarries of Pentelicus, and those of Agrigentum, of a fossil conglomerate which the place itself furnished.

Résumé.

RÉSUMÉ.—Taking now a rapid view of what we owe to the Greeks as architects, we may assume that the invention of columnar architecture is due to the Assyrians; but how far this had advanced before the Greeks began to practise it, we cannot as yet exactly determine. There is no doubt, however, that it owed to the Greeks the greater part of its beautiful and delicate details. Some of the finest examples of these are to be found at Athens in the Theseum, Parthenon, Propylæa, and Erechtheum, ranging in date from 469 to 409 B.C. Not only do we find there the most beautiful mouldings and other ornaments, but the most refined methods of obviating the minute defects in outline supposed to be caused by optical illusion. The lines of the shafts, for instance, in place of being perfectly straight, were slightly expanded between the base and necking, so as to form a very delicate curve (entasis). The apparent depression of the top of the cornice, supposed to be caused by the extra weight in the centre of the pediment, was obviated by curving the cornice so that the centre part was the highest. The steps were curved in a similar way. Then the whole of the columns of the peristyle sloped towards the centre. The architrave and frieze in the Parthenon followed the same slope of about 1 in 80, but its boldly overhanging cornice and antefixæ sloped forwards about 1 in 100.

We owe also to the Greeks one new form in art—the pediment. It is not found in Egypt; some slight suggestions as to its use may, perhaps, be found in the sculptures of Assyria, but in Greece it forms the crowning feature of every temple; and simple as the invention may seem, it led the way to a succession of others, which resulted in the grand gables of our Gothic architecture.

The details of the Grecian temples were heightened by colour and gold. Of the former, Dr Faraday detected many traces on the sculptures of the British Museum; and clear indications of it have been found in many of the ruins both in Greece proper and in the colonies. In fact, colour, or tinting of some kind, seems to have been absolutely requisite in order to relieve the monotonous and dazzling effect of new white marble. A striking example of this occurred recently when the palace of the king was built at Athens. The newly-worked marble had much the appearance of a smooth stucco or brilliant whitewash. But this would serve (and doubtless did serve in ancient times) as an admirably delicate base for decorative work in colour and gold.

What the effect was of a Greek temple, in all its glory, we can no more judge than we can in the case of one of ancient Egypt. For there is not one that is not a mere wreck; and even the most ambitious of modern copies, the Walhalla, wants the exquisitely delicate material out of which the Parthenon was wrought, and the sculpture which no modern Phidias was living to supply. But in Greece proper there was but this one type, viz., that of the pedimented temple with its colonnade. There was no arch, as in Assyria, to span an opening too wide for a stone beam; no dome to vary the outline by its bold and graceful form; no curved outline, as at Mycenæ, to vary that of the rectangle.

The form adopted by the Greeks was worked out in a manner which leaves all others of ancient art, wrought in the same likeness, far behind; and the details which adorned that form charm the eye with their exquisitely chaste beauty. But in our admiration of them we must not forget that numerous other forms, beautiful in themselves, and familiar in their beauty to the Assyrians and Pelasgi, as they are to us were unknown to, or neglected by, the Greeks.

Etruscan Architecture.

Little of the history of Etruria is as yet known, for accounts of Roman historians are not to be relied on, and the Etruscan language is as yet unread. Our acquaintance with its architecture, too, is very meagre, for the comparatively few remains show us simply the forms used by the Etruscans in their tombs; and even these have been as yet imperfectly explored, owing to the nature of the climate, and the desolation of those parts of the country in which they are chiefly found. Little was, in fact, known of them at all until the careful descriptions of Sig. Canina and Mr Dennis appeared, from whose works the principal ascertained facts are derived. The sites of the Etruscan towns are nearly all on or near a line, curving slightly from the sea, extending from Fiesole, near Florence, through Arretium, Cortona, Volsinii, and Falerii, to Rome. The only sites of much importance near the sea were Cossa and Tarquinii. The towns were generally planted on the tops of high hills, as if for the purpose of defence. Much of the town-walling remains in various places, as at Fiesole, Cortona, Cossa, and Volterra, and furnishes grand examples both of the polygonal and of the squared masonry, which has been described as belonging to the early period of Greek architecture.

The tombs were of two classes, the first being nearly of the same external form as that described at Tantalais, viz., with a massive stereobate, circular in plan, having one or more chambers in the centre of it, and above it a tumulus of earth. Of these, hundreds of specimens of various sizes remain. At Volci there was one 240 feet in diameter. The grandest of all is, perhaps, that at Cervetri, drawn by Canina, and known as the Regulini Galeassi. The chambers here, and in other instances, are ceiled with oversailing courses of stone, cut into an arched form as at Mycenæ. A completely voussoired arch exists over a tomb chamber, known as the Grotto of Pythagoras, at Cortona, but the date of this is very doubtful. In these tombs have been found some of the beautiful specimens of jewellery which adorn the museums of Europe. The mouldings used are very few and simple, but of a section which is quite peculiar to Etruria. They occur in two places only, viz., as a base, and as a capping to the basement. In none of the tombs of the kind above described are found any of the paintings which form so characteristic a feature in the second and better known class of tombs, viz., those cut in the face of the rock in the vicinity of most of the Etruscan towns. The apparent entrances to these tombs are by doorways of a peculiar form, and often placed very high up the rock. But these are false, and merely carved in it, the real entrance being often 40 to 50 feet below. This leads into one or more chambers, which are mostly square, but in some few instances are circular, as at Chiusi, where there is one 25 feet in diameter, supported by a pillar in the centre. Whatever their shape, they are cut out of the solid rock; and, apparently, bore some resemblance to the house which the occupant of the tomb had inhabited during life. None of the chambers are domed or vaulted, all the ceilings being cut in the shape of flat beams or sloping rafters supported by pillars,—another instance of the construction of built edifices being copied in rock-cut caves. One of these, at Cervetri, is given in D'Agincourt's work. There is another chamber at Tarquinii, 50 feet square, supported by four pillars, each 6 to 7 feet square.

The manner in which the chambers were fitted up depended on the mode of burial. Cremation was sometimes used, and then, as at Veii, Sutri, and Toscanella, we find niches for urns. But usually there was a bench cut in the rock round the sides of the chambers, and on them were ranged the sarcophagi, of which specimens are so well known in most of the museums of Europe. In some instances, which seem of a late date, the bodies were placed in recesses.

The paintings which decorated the chambers were very peculiar, being of the same character, and with figures of divinities, &c., of the same well-known attenuated forms as are found in the earlier vases. The colouring is as peculiar as the drawing, *e.g.*, at Veii there is a horse depicted with a red neck, yellow mane and tail, one leg yellow spotted with red, and the rest of the horse black. At Tarquinii is another horse with blue mane and hoofs, white tail, and all the rest red. All these paintings were executed, much as were those of the Greeks and Egyptians, on a very thin coating of fine stucco over the rock. In the later tombs domestic scenes appear to have taken the place of the allegorical ones formerly used.

One of the best examples, though of very late (Roman) date, is a tomb at Cervetri. The chamber was supported on two pillars. In each side of it were recesses, 2 feet in height, each having a bed, with cushion for the head, tassels, &c., all sculptured and painted. The sides and pillars were decorated with painting and sculpture, representing the helmets, shields, swords, and other accoutrements of the officer whose tomb it was. But there were also depicted in the same way the personal ornaments of his wife, her mirrors, jewellery, &c. Her slippers are marked on the floor, and by the side of the recess near, is carved her husband's walking-stick. Even the kitchen utensils appear in effigy, so as to give the whole fittings of the house of a Roman officer.

Another class of funeral monument is described to us by some writers, the most noted example being that of the great King Porsena, but the descriptions are too vague to allow of even this being restored with certainty. It is said to have had three ranges of pillars, the lowest one 150 feet high and 75 feet square, standing on a basement 300 feet square. There were five sets of these pillars, viz., one at each angle and one in the centre, and they are said to have been enriched with bronze ornamental work at the top of each division. This class of tomb was probably somewhat like one of late date, near Rome, which has been known by various names (the tomb of the Horatii and Curiatii, of Aruns, of Pompey, &c.), and if there were two ranges of pillars above, all tied in with metal rings at the point of junction, it would agree tolerably well with what we read of Porsena's tomb.

Of Etruscan temples no remains exist, and the accounts of them are so conflicting that any restoration of them must be very uncertain.

Roman Architecture.

We have taken it for granted that the Greeks were ignorant or neglectful of the properties of the arch. If the great sewer at Rome, called the Cloaca Maxima, belongs to the time of Tarquinius Priscus, it must be conceded that the properties of the arch were known, and the arch constructed in that city. But it is contended that the Cloaca Maxima, as it now exists, is a work of much more recent date, and that it may have succeeded the sewer constructed by the first Tarquinius, who was, moreover, himself a Greek. It is, however, now certain that the construction of the arch was known to the Egyptians, and used by them at a very early date, although, for some reason which we do not quite understand, they neglected it in their greatest works. That it was known to and made great use of by the Assyrians is also certain. Whoever it was that invented it, and at whatever date, the Romans made extensive practical use of it, and by its means they succeeded in doing what their predecessors in civilisation had never effected. It enabled

Use of the arch.

them to carry secure and permanent roads across wide and rapid rivers, and to make a comparatively fragile material, such as brick, more extensively useful than the finest marble was in the hands of the Greeks. To the Greeks, however, the Romans were indebted for their knowledge of the more polished forms of columnar architecture. Before the conquest of Greece the structures of Rome appear to have been rude and inelegant, and from that time the existing style of architecture either gave place to the superior merit and beauty of what the Romans found in that country, or was combined with it, though frequently the combination tended to destroy the beauty of both.

Comparison of Greek and Roman architecture.

In the transference of Greek columnar architecture to Rome, a great change was effected independently of those combinations, for the Romans could not appreciate the simple grandeur and dignified beauty of the Doric, as it existed in Greece. They appear to have moulded it on what we suppose their own Tuscan to have been; and the result was the mean and characterless ordinance exemplified in the lowest story of the theatre of Marcellus at Rome, and in the temple at Cora, between 30 and 40 miles south of that city. Not less inferior to the Athenian examples of the Ionic order, than the Doric of Cora is to the Doric of Athens, are the mean and tasteless deteriorations of them in the Roman temples of Fortuna Virilis and Concord. It was different, however, with the foliated Corinthian, which became to the Romans what the Doric had been to the Greeks—their national style. But though they borrowed the style, they did not copy the Greek examples. In Rome the Corinthian order assumed a new and not less beautiful form and character, and was varied to a wonderful extent, but without losing its original and distinctive features. The temple of Vesta, at Tivoli, differs from that commonly, but erroneously, named the temple of Jupiter Stator, in Rome, as much as the latter does from the choragic monument of Lysicrates at Athens; all three are among the most beautiful examples of the Corinthian order in existence,—if indeed they are not pre-eminently so,—and yet they do not possess a single proportion in common. It must be confessed, moreover, that if the Romans had not good taste enough to admire the Doric and Ionic models of Greece, they had too much to be fond of their own; for they seldom used them. Both at home and abroad, in all their conquests and colonies, wherever they built, they employed the Corinthian order. Corinthian edifices were raised in Iberia and in Gaul, in Istria and in Greece, in Syria and in Egypt; and to the present day, Nismes, Pola, Athens, Palmyra, and the banks of the Nile, alike attest the fondness of the Romans for that peculiar style. We cannot agree with the generally received opinion, that Greek architects were employed by the Romans after the connection between the two countries took place; for the difference between the Greek and Roman styles of architecture is not merely in the preference given to one over another peculiar mode of columnar arrangement and composition, but a different taste pervades even the details though the mouldings are the same; they differ more in spirit and character than do those of Greece and Egypt, which certainly would not have been the case if Roman architecture had been the work of Greek architects. Indeed, were it not for historical evidence, which cannot absolutely be refuted, an examination and comparison of the architectural monuments of the two countries would lead an architect to the conclusion, that the Corinthian order had its origin in Italy, and that the almost solitary perfect example of it in Greece was the result of an accidental communication with that country, modified by Greek taste; or that the foliated style was common to both, without either being indebted to the other for it. If, however, Greek architects were employed by the Romans, they must have made their taste and mode of design conform to those of their conquerors much more readily than we can imagine they would as the civilised slaves of barbarian masters; and it cannot be disputed that the Roman architecture is a style essentially distinct from the Greek. This is apparent from the fact that many of the minor works of sculpture in connection with architecture, such as candelabra, vases, and various articles of household furniture, discovered at the villa of Adrian, near Tivoli, and at Herculaneum and Pompeii, are fashioned and ornamented in the Greek style, while others are as decidedly Roman in those particulars,—rendering it evident that such things were either imported from Greece, or that Greek artists and artisans were employed in Italy, who retained their own national taste and modes of design. It is probable that both the architects and the artists, natives of Rome, modified their own less elegant productions by reference to Greek models; but that the Romans derived their architecture entirely from the Greeks, may certainly be disputed.

Building materials.

Much of the extent and magnificence of the architectural works of the Romans is attributable to their knowledge and use of the arch, which enabled them to utilise inferior materials. Almost all their structures were of brick—aqueducts, palaces, villas, baths, and temples. Of the present remains, only a few columns and their entablatures are of marble or granite, and two or three buildings are of Travertine stone,— all the rest are brick. The Colosseum, the mausoleum of Adrian, the tunnel sewer, the temple of Fortuna Virilis, and the ancient bridges on the Tiber, are of Travertine stone; the remaining columns of the more splendid temples, the internal columns, and their accessories, of the Pantheon, the exterior of the imperial arches, and the cenotaph columns of Trajan and of Antonine, are of marble; but the Imperial Mount of the Palatine, which holds the ruins of the palace of the Cæsars, is one mass of brick; the Pantheon, except its portico and internal columns, &c., is of brick; the temples of Peace, of Venus and Rome, and of Minerva Medica, are of brick; and so, for the most part, were the walls of others, though they may have been faced with marble or freestone. The baths of Titus, of Caracalla, and Diocletian, are of brick; the city walls are of brick; so are the extensive remains of the splendid villa of Adrian, and those of the villa of Mæcenas at Tivoli; the palaces of the Roman emperors and patricians at Baiæ and in other parts of Italy; and so, it may be said, are the remains of Herculaneum and Pompeii, for the houses in these cities are generally built of alternate double courses of brick and courses of stone or lava. In most cases, at Rome and in the provinces, stucco formed the surface which received the decorations. From the above enumeration, it will appear how much more variously the Romans built than any of their predecessors. In Egypt we find no indications of edifices of real utility or convenience, nothing but temples and tombs,—and in Greece there is but a small addition to this list; but in Rome are found specimens of almost every variety of structure that men in civilised communities require.

The Roman Corinthian.

Like the Greek orders the Roman Corinthian may be said to consist of three parts,—stybolate, column, and entablature; but, unlike them, the stylobate is much loftier, and is not graduated, except for the purposes of access before a portico. Its usual height is not exactly determinable, in consequence of the ruined state of most of the best examples; but it may be taken at from two and a half to three diameters. In the triumphal arches the height of the stylobate sometimes amounts to four, and even to five diameters. It is variously arranged, moreover, having, in the shallower examples, simply a congeries of mouldings to form its base, with, perhaps, a narrow square member under it, a plain dado, and a covering cornice or coping, on the back of which the columns rest. In the loftier examples a single and sometimes a double plinth comes under the base mouldings; and a blocking course rests upon the coping, to receive the bases of the columns. This last is only necessary when the height of the stylobate is such as to take the columnar base above the human eye, when the coping cornice would intercept it if a blocking course did not intervene.

The column (Plate XIV.) consists of base, shaft, and capital, and varies in height from nine and a half to ten diameters. The base has, ordinarily, in addition to the diminishing congeries of mouldings which follows the circular form of the shafts, a square member or plinth, whose edges are vertical; with this the whole height of the base is about half diameter. The rest of this part of the column is variously composed, but it generally consists of two plain tori and a scotia, with fillets intervening, as in Greek examples of this order, but differently proportioned and projected, as the examples indicate. Sometimes the scotia is divided into two parts by two beads, with fillets, as in the Jupiter Stator example, in which also a bead is placed between the upper torus and the fillet of the apophyge. The spread of the base varies from a diameter and one-third to a diameter and four-ninths. In the best Roman examples, as well as in the Greek, the shaft diminishes with entasis; the average diminution is one-eighth of a diameter. The shaft was always fluted when the material of which it was composed did not oppose itself; for the Romans often used granites, and sometimes an onion-like marble, called therefore *cipollino*, for the shafts of columns; the former of which could not be easily wrought and polished in flutes, and the latter would scale away if it were cut into narrow fillets. Like the Greek Corinthian and Ionic orders, the Roman Corinthian has twenty-four fillets and flutes. The flutes are generally semicircles, and they terminate at both ends, for the most part with that contour. Dividing the space for a fillet and a flute into five parts, four are given to the latter, and one to the former. The hypotrachelium is a plain torus, about half the size of the upper torus of the base, or half the width of a flute, as these nearly correspond; it rests on a fillet above the cavetto at the head of the shaft.

The ordinary height of the capital is a diameter and one-eighth; but there is a very fine example, in which it barely exceeds a diameter, and another in which it is not quite so much. It is composed of two rows or bands of acanthus leaves, each row consisting of eight leaves ranged side by side, but not in contact; of helices and tendrils trussed with foliage; and an abacus, whose faces are moulded and variously enriched. The lower row of acanthus leaves is two-sevenths the whole height of the capital; the upper row is two-thirds the height of the lower above it, and its leaves rest on the hypotrachelium below, in the spaces left between the others. They are placed regularly, too, under the helices and tendrils above, which support the angles, and are under the middle of each side of the abacus. The construction and arrangement of the next compartment above must be gathered from the examples, for a competent idea cannot be conveyed in words. The abacus is one-seventh of the height of the capital; in plan it is a square whose angles are cut off, and whose sides are concaved in segments of a circle, under an angle at the centre of from 55° to 60°. Its vertical face is generally a flat cavetto, with a fillet and carved ovolo corbelling over at an angle of about 125°. The cavetto is sometimes enriched with trailing foliage, and a rosette or flower of some kind overhangs the tendrils from the middle of each side of the abacus.

Every example of this order differs so much from others in the form, proportion, and distribution of the various parts of its capital particularly, that it cannot be described in general terms like the Greek Doric and Ionic. The example referred to in the definition is that of the so-called Jupiter Stator, the most elegant, perhaps, of all the Roman specimens (Plate XIV. ex. 1).

The entablature varies in different examples from one diameter and seven-eighths to more than two diameters and a half in height. Perhaps the best proportioned are those of the portico of the Partheon (Plate XIV. ex. 4) and of the temple of Antoninus and Faustina (Plate XIV. ex. 3), the former being rather more than two diameters and a quarter, and the latter rather less than that ratio. The entablature of the Jupiter Stator example is more than two diameters and a half in height, of which the cornice alone occupies one-sixth more than a full diameter, leaving to the frieze and architrave somewhat less than one diameter and a half between them. In this latter particular it nearly agrees with the other two quoted examples, so that the great difference in the general height is in the cornice almost alone, the cornices of the others being about a sixth less, instead of as much more, than a diameter in height. The Roman Corinthian entablature may be taken, then, at two diameters and a quarter in height. Rather more than three-fifths of this is nearly equally divided between the architrave and frieze, the advantage, if any, being given to the former; the cornice, of course, takes the remaining two-fifths, or thereabouts. The architrave is divided into three unequal fasciæ and a small congeries of mouldings, separating it from the frieze. The first fascia is one-fifth the whole height; one-third of what remains is given to the second, and the remainder is divided between the third fascia and the band of mouldings,—two-thirds to the former, and one to the latter. A bead, sometimes plain and sometimes carved, taken from the second fascia, which is itself enriched in the Jupiter Stator example, marks its projection over the first; and a small cyma-reversa, carved or plain as the bead may be, taken from the third fascia, marks its projection over the second. The band consists of a bead, a cyma-reversa, carved or plain according to the general character of the ordinance, and a fillet. In non-accordance with the practice of the Greeks, the face of the lowest or first fascia of the architrave, in the Roman Corinthian, impends the face of the column at the top of the shaft, or at its smallest diameter; and every face inclines inwards from its lowest face up. The whole projection of the architrave, that of the covering fillet of the band, is nearly equal to the height of the first fascia. The frieze impends the lowest angle of the architrave. Its face is either perpendicular, or it slightly inclines inwards, like the fasciæ of that part of the entablature: in some cases it is quite plain, and in others is enriched with a foliated composition, or with sculptures in low or half relief. The cornice consists of a deep bed-mould, variously proportioned to the corona; but it may be taken generally, when it has modillions, at three-fifths, and when it has none, at one-half of the whole height. It is composed of a bead, an ovolo or cyma-reversa, and a fillet, a plain vertical member, sometimes dentilled, another bead, and a cyma-reversa, with fillet or ovolo, as the lower may *not* be; this is surmounted, when modillions are used, by another plain member, with a small carved cyma-reversa above it. On this the modillions are placed, and the cyma breaks round them. They are about as wide as the member from which they project, and are about two thicknesses apart. In form they are horizontal trusses or consoles, with a wavy profile, finishing at one end in a large, and at the other in a small volute; and under each there is generally placed a raffled or acanthus leaf. In proportion-

ing the parts of this bed-mould in itself, one-third of its height may be given to the modillion member, and the other two-thirds divided nearly equally, but increasing upwards into three parts, one for the lowest mouldings, one for the plain or dentil member, and the third, and rather largest portion, for the mouldings under the modillion member. The mouldings of this part of the cornice are carved or left plain, according to the character of the ordinance; and its greatest projection, except the modillions themselves, that of the modillion member, is about equal to half its height. The upper part of the cornice—the corona, with its crown-mouldings—consists of the vertical member called the corona, which is two-fifths the whole height;—this, in the examples of the temples of Jupiter Stator and Antoninus and Faustina, is enriched with vertical flutes;—a narrow fillet, an ovolo, and a wider fillet, occupy one-third of the rest, the other two-third being given to cyma-recta, with a covering fillet which crowns the whole. Its extreme projection is nearly equal to the whole height of the cornice.

The ordinance of the temple of Vesta, or of the sibyl, at Tivoli (Plate XIV. ex. 2), whose entablature is the very low one mentioned, is not generally in accordance with the scale we have given, and it must be referred to for its own peculiar proportions.

Pediments with the Roman Corinthian order are found to be steeper than they were made by the Greeks, varying in inclination from 18° to 25°; but they are formed by the cornice of the entablature in the same manner. Antefixæ do not appear to have been used on flank cornices as in Greek ordinances, in which the cymatium is confined to pediments; but in Roman works it is continued over the horizontal or flank cornice, as we have described; and frequently it is enriched with lions' heads, which were at the first introduced as waterspouts. The planceer or soffit of the corona is, in the Jupiter Stator example, coffered between the modillions, and in every coffer there is a flower. The soffit of the entablature in this order is generally panelled and enriched with foliated or other ornament. The intercolumniation is not the same in any two examples. In the temple of Vesta, in Rome, it hardly exceeds a diameter and a quarter; in the Jupiter Stator example it is a fraction less than one diameter and a half, in that of Antoninus and Faustina, nearly a diameter and three quarters; in the portico at Assisi, rather more than that ratio; in the portico of the Pantheon, almost two diameters; and in the Tivoli example, a fraction more than that proportion.

The antæ of the Roman Corinthian order are generally parallel; but pilasters are mostly diminished and fluted as the columns. Of two of the existing examples of antæ, in one—that of the temple of Mars Ultor—they are plain, to fluted columns; and in the other—that of the Pantheon portico—they are fluted, to plain columns. The capitals and bases are transcripts of those of the columns, fitted to the square forms.

Ceilings of porticoes are formed, as in the Greek style, by the frieze returning in beams from the internal architrave to the wall or front of the structure, supporting coffers more or less enriched with foliage or flowers. This, however, could only have been effected when the projection was not more than one, or at the most two, intercolumniations, if stone was used; and it is only in such that examples exist. Porticoes ordinarily must have had arched ceilings, as that of the Pantheon has, or the beams must have been of wood; in the latter case the compartments of the ceiling would probably be larger. How it was arranged in the former we cannot tell, as the arches only remain, and they may not be of the date of the rest of the portico.

The Roman Composite.

The ancient examples of what is called the Composite order (Plate XV. ex. 2) do not differ so much from the ordinary examples of the Corinthian as the latter do among themselves, except in the peculiar conformation of the capital of the column. In other respects, indeed, its arrangement and general proportions are exactly those of the Corinthian. The Composite was used in triumphal arches, and, in the best ages of Roman architecture, in them alone. The difference in the capital consists in the enlargement of the volutes to nearly one-fourth the whole height of the capital, and in the connection of their stems horizontally under the abacus, giving the appearance of a distorted Ionic capital. The central tendrils of the Corinthian are omitted, and the drum of the capital is girded under the stem of the volutes by an ovolo and bead, as in the Ionic. Acanthus leaves, in two rows, fill up the whole height from the hypotrachelium to the bottom of the volutes, and are consequently higher than in the Corinthian capital: this difference is given to the upper row. Besides this Composite, however, the Romans made many others, the arrangements and proportions of the ordinances being generally those of the Corinthian order, and the capitals corresponding also in general form, though in themselves differently composed. In these, animals of different species, the human figure, armour, a variety of foliage, and other peculiarities are found. Shafts of columns also are sometimes corded or cabled instead of being fluted: those of the internal ordinance of the Pantheon are cabled to one-third their height, and the flutes of the antæ of that ordinance are flat, eccentric curves. There are fragments of others existing, in which the fillets between the flutes are beaded; some in which they are wider than usual, and grooved; others, again, whose whole surface is wrought with foliage in various ways; and it would be no less absurd to arrange all these in different orders, than to make a distorted and hybrid capital the ground-work of an order.

The Roman Ionic.

The only existing example of Ionic in Rome, in which the columns are insulated, is in the temple of Fortuna Virilis (Plate XV. ex. 3; Plate XVI. fig. 12), for the temple of Concord is too barbarous to deserve consideration. Its stylobate, like that of the Roman Corinthian, is lofty and not graduated, having a moulded base and cornice or surbase. In the column the base consists of a plinth, two tori, a scotia, and two fillets; the shaft has twenty fillets and flutes, and diminishes one-tenth of a diameter; the capital is two-fifths of a diameter in height, the volutes, however, dip a little lower, being themselves about that depth without the abacus; the corbelling for the volutes is formed by a bead and large ovolo,—the latter being carved. A straight band connects the generating lines of the volutes, whose ends are bolstered and enriched with foliage; and a square abacus, moulded on the edges, covers the whole. In the entablature the architrave is unequally divided into three fasciæ and a band consisting of a cyma-reversa and fillet; the lowest angle impends the upper face of the shaft of the column. The frieze is in the same vertical line, and is covered with a fillet which receives the cornice; it is also enriched with a composition of figures and foliage. The cornice consists of a bed-mould, two-fifths of its height, and a corona with crown-mouldings. The cymatium is enriched with acanthus leaves and lions heads, and the mouldings of the bed-mould and architrave band are carved. The soffit of the corona is hollowed out in a wide groove, whose internal angles are rounded off in a cavetto, but without ornament of any kind, forming indeed a mere throating. Like the angular capitals of the Greek

Ionic, the external volute of this is turned out and repeated on the flank: either that or the abuse of it in the Composite capital gave rise to distortions of this order, in which all the volutes of the capital are angular, and consequently all its four faces are alike. In other respects, however, it does not differ generally from the ordinary Roman examples of Ionic. The temple of Fortuna Virilis is pseudo-peripteral, and consequently has neither antæ nor pilasters, nor do ancient examples exist of either.

The Roman Doric.

The Roman Doric is even a ruder imitation of the Grecian original than the mean and tasteless deterioration of the voluted Ionic is of the graceful Athenian examples. The specimen of it which is considered preferable to the others is that of the theatre of Marcellus, in Rome (Plate XV. ex. 4). The column is nearly 8 diameters in height: it consists of shaft and capital only. The shaft is quite plain, except fillets above and below, with escape and cavetto; and it diminishes one-fifth of its diameter. The arrangement of the capital, composed of a torus, the necking, and three deep fillets, with a semitorus, surmounted by the abacus, is shown in Plate XV. ex. 4. The corona and crown-mouldings of the cornice being destroyed, the whole height of the entablature cannot be correctly ascertained; but from analogy it may be taken, with the bed-mould, part of which exists, at about two-thirds of a diameter, making, with the architrave and frieze, an entablature nearly 2 diameters high. Of this the architrave is exactly half a diameter. Three-tenths of its depth are unequally occupied by the tænia, regula, and guttæ, the last of which are six in number, and truncated semicones in form. The rest of the surface of the architrave is plain and vertical, impending a point rather within the superior diameter of the column. A fascia, one-eighth of its own height, bands the frieze above the triglyphs; the rest of its surface is plain vertically, but horizontally it is divided into triglyphs, half a diameter in width, and placed over the centres of the columns. The space between the triglyphs is equal to the height of the frieze without its plat-band or fascia, making in effect perfectly square metopes. All that can be traced of the cornice is a small cyma-reversa, immediately over the frieze, and a square member with dentils on it. In the example, the cornice is completed from that of the Doric of the Colosseum.

The temple at Cora presents a singular specimen of the Doric order, evidently the result of an examination of some Greek examples, but moulded to the Roman proportions and to Roman taste. The columns are enormously tall, but the shafts are partly fluted and partly chamfered for fluting, like the Greek. The capital is ridiculously shallow, but the abacus is plain, and the echinus of a somewhat Hellenic form. The entablature is very little more than a diameter and one-third in height, and the architrave of it is shallower even than the capital; but the frieze and cornice are tolerably well proportioned, though the triglyphs in the former are meagre, narrow slips, and the latter is covered by a deep widely-projecting cavetto, that would be injurious to even a better composition. Instead of regular mutules with guttæ, the whole of the planceer of the cornice is studded with the latter; but, like the Greek, the triglyph over the angular column extends to the angle of the architrave, which does not appear to have been the practice of the Romans; yet the reason for this does not appear to have been understood, for the external intercolumniations are the same as the others.

As far as we have the means of judging, the Romans made the antæ of their Doric similar to the columns, only that they were, of course, square instead of round; though, indeed, an attached column appears to have been generally preferred.

It is, however, to be remembered, that these two orders, the Ionic and Doric of the Roman school, ought hardly to be considered as belonging to the architecture of the Romans. They are merely coarse and vulgar adaptations of the Greek originals, of which we now possess records of the finest examples. Yet their meanness and tastelessness, when compared with the Grecian models, more strikingly evince the superiority of the latter, and show to what extent the architects of the Italian school must have been blinded by their system, when they fancied such wretched examples to be beautiful.

Roman Mouldings and Ornament (Plate XIII.)

The mouldings used in Roman architectural works are the same as the Grecian in general form, but they vary materially from them in contour. The Roman cyma-recta is projected much more than the Greek, with a deeper flexure. The ovolo is represented in the Roman style by a moulding whose outline is nearly the convex quadrant of a circle, or a quarter round, and sometimes it is nearly that of the quadrant of an ellipse. The Roman torus is either a semicircle or a semi-ellipse; and the bead is a torus, except in its application, and in being smaller, and generally projected rather more than half the figure whose form it bears. The cavetto, in Roman architecture, is nearly a regular curve, being sometimes the concave quadrant of a circle, or the reverse of an ovolo, and sometimes a smaller segment. A Roman scotia is more deeply cut, and is consequently less delicate than the same member in a Greek congeries: its form frequently approaches that of a concave semi-ellipse.

The enrichments of Roman mouldings are, for the most part, similar to those of the Greek, but less delicate and graceful both in design and drawing. Those of the cyma and ovolo are particularly referred to, but the Romans used others besides. Raffled leaves form a favourite enrichment in the architecture of the Romans; indeed these are hardly less frequent in their works than the honeysuckle is in those of the Greeks. Mouldings were enriched with them; and a raffled leaf masks the angles of carved cymas and ovolos in the former, as a honeysuckle does in the latter. Nevertheless, the honeysuckle and lotus are both found in Roman enrichments, particularly the latter, and perhaps even more than in Greek. It is not uncommon to find examples of Roman architecture completely overdone with ornament,—every moulding carved, and every straight surface, whether vertical or horizontal, sculptured with foliage or with historical or characteristic subjects in relief.

Particular Roman Structures.

TEMPLES.—Whatever forms were adopted from the Greeks by the Romans were rapidly altered by the latter. The temples, for example, were, no doubt, constructed, in the main, after the Greek model. But we find three-quarter columns used in the flanks, as at the temple of Fortuna Virilis at Rome and at Nismes, in place of the open peristyle or the plain flat wall. These three-quarter columns were, it is true, used at the rear of the Erechtheum and at the temple of the Giants at Agrigentum. But these were quite exceptions. Then, in the portico of the Pantheon (Plate XVI. fig. 4) the Romans availed themselves of the properties of the arch to effect an immense change in the internal design and appearance. Temples.

From the forest of columns, as at the Parthenon, all placed at equal distances, or nearly so, the Romans boldly removed four rows (two in centre and one at each side, as at the Pantheon, Plate XVI. fig. 5), arched over the space thus left, and so obtained a picturesque effect quite un-

known to the Greeks. Then the ends were rounded off into apses, and the same was done at the temple of Venus and Rome. In each of the above cases the exterior still conformed almost entirely to the outlines of the Greeks. But we now come to the circular edifices, as the temple of Minerva Medica, 110 feet in diameter, and the Pantheon, 139. As to the age of these and their purpose there is some doubt; but there can be none as to the temples of Vesta at Tivoli and Rome, which have an external peristyle of columns, and thus present an entirely new form. Whether these temples were finished with domes or not is doubtful. In any case the exterior would probably have shown merely a sloping roof, as has been common enough in Italy down to late times.

Theatres.

THEATRES.—The best remaining specimens of Roman theatres are those of Pompeii and Herculaneum. Like those of the Greeks, they rest on the side of a hill, but instead of being hewn out of the hill they are built on it. Others in a more or less ruined state remain in Italy, France, Sicily, &c., *e.g.*, at Rome, Verona, Pola, Taormina, and Arles. At first they were of wood, and one by Æmilius Scaurus, 58 B.C., is said to have held 80,000 spectators. That they were copied mainly from the Greeks there can be no doubt. In fact, one built by Pompey is expressly stated to have been copied from another at Mytilene, and their general form is very similar to that of the Greek theatre. But the Roman theatre received a greater degree of architectural decoration than the Greek. Of this the theatre of Marcellus, in Rome, is an example; for though otherwise destroyed, its external wall remains and presents columnar ordinances, with intervening arches in stories, according to the practice of the Roman school.

Amphitheatres

AMPHITHEATRES.—These are altogether Roman in general design. The first is said to have been built by Julius Cæsar, and others were afterwards built by Caligula and Nero. The first of stone is said to have been the Colosseum, built by Vespasian and Titus, and so called from the Colossus of Nero which stood near. It was injured and then restored under Severus and Decius, in whose time it is probable that the upper row was added. As to the awning, we know that the main portion at least of the audience was protected from the fierce rays of the sun by a strong velarium. This was supported on the outside by heavy masts, which passed through holes still existing in the top cornice, and stepped down on to the corbels, which show so conspicuously in the top order. Recent excavations have disclosed the original arena, about 20 feet below the present level of the ground. Evidence has also been obtained that the arena was sometimes a movable platform. To obtain an approximate idea of the size of this enormous structure, we must remember that the Albert Hall (the largest diameter of which is 276 feet) could have been placed in the arena alone of the Colosseum, the exterior of which measures 622 feet by 528 (Plate XVI. fig. 1). Other amphitheatres of great size were constructed in the various towns of the empire. Amongst them we may mention that at Verona, 500 feet by 404, and Nismes (still used for public shows), 434 by 340. Extensive remains of another, 376 feet by 220, have been discovered recently at El-Djemm, in Tunis. (See AMPHITHEATRE, vol. i. pp. 774–776.)

Tombs.

TOMBS.—Some very grand examples of tombs of circular forms remain, as well as many others of great beauty. It must be remembered that with the Romans both burial and cremation were used. The columbaria (vaults lined with small recesses for the urns, which contained the ashes of the dead) present the most ordinary specimens of architectural forms adapted to cremation. The sarcophagus, of which that of the Scipios is the best known example, presents the ordinary form used in connection with burial. But when the family of the deceased was rich or distinguished, the ashes or the sarcophagi were enclosed in buildings of the most magnificent kind. The tomb of Cecilia Metella, so well known to all by Byron's beautiful lines in *Childe Harold*, commencing—

> "There is a stern round tower of other days,"

is a bold tower 90 feet in diameter and 62 feet high, so solidly built as to contain only a chamber 19 feet in diameter. Much grander was the mausoleum of Augustus, which has perished. Of the mausoleum of Hadrian the skeleton only remains. But it shows that the base was 170 feet square, supporting a circular edifice 115 feet in diameter. It would seem that this mass, now formed into the castle of St Angelo, and showing the naked brickwork, had, in its glory, two ranges of marble columns and probably a domed roof. From its position on the banks of the Tiber, near the bridge, it must have formed one of the grandest architectural compositions of the Romans.[1]

Forums.

FORUMS.—At first these great buildings were used for merchants, and were open spaces with porticoes, shops, counting-houses, &c., all round. The best example existing is, perhaps, that of the Forum of Pompeii. In later times these erections expanded into grand architectural ranges of porticoes, with statues, &c. Leading out of them, in various positions, were temples, law courts, theatres, &c. It was in Trajan's Forum that his famous column was erected.

Aqueducts.

The AQUEDUCTS show little of the skill of the architect, but they are very picturesque as they stretch along the Campagna and other places. Across a valley, at Tarragona, one rises to a height of 100 feet, and another, the Pont du Gard, at Nismes, to 180. But they do not reach the level of true architectural beauty, and derive their chief value from their immense length and size. (See AQUEDUCT, pp. 219–221 of the present volume.)

Triumphal arches.

The TRIUMPHAL ARCH is peculiarly Roman, and it is in this form that the arch appears to have been most boldly used as an external feature. The arch is, in fact, the form to which all other parts of the structure are mere decorative adjuncts. The principal examples are the arches of Titus, Severus, Janus, and Constantine at Rome, and that of Trajan at Ancona.

Dwellings.

DWELLINGS.—The still extensive remains of the villa of Hadrian, near Tivoli, bespeak its original magnificence. Everything appears to have been directed to internal splendour and effect alone; and, indeed, all collateral evidence tends to the conclusion, that the exterior of Roman palaces and mansions was not heeded, being merely plain brick walls. This is the case at Pompeii, and the ruins of mansions in various parts of Italy, from that of Sallust on the Benacus or Lago di Garda, to those of other Roman nobles on the shores of the Bay of Baiæ, present no indications whatever that their exteriors were subjected to architectural decoration. The palace of Diocletian at Spalatro, and the splendid remains of Baalbec and Palmyra, some of which, perhaps, belonged to secular structures, offer evidence to the contrary of this, if they are correctly restored in the works which treat of them. Notwithstanding the extent of the structure and its general magnificence, however, the

[1] Singular enough, mausoleums, though they have been destroyed in Greece and Rome, have been preserved in Africa. There we have a singular structure, the Medricen, in Algeria, 180 feet in diameter, with a row of engaged columns of a rude Doric type as a stereobate, and on these a series of gradini. The whole outline greatly resembles that of the circular Etruscan-built tombs already described. Much grander and more ornate is the Koubr, also in Algeria, which is of the same form, but 200 feet in diameter, and 108 feet high to the platform at top. The order is a curious imitation of the Erechtheum Ionic. The Medricen has not been entered, at least, in modern times. The Koubr has a singular arched passage, entered from below the ground-level, and winding all round to a chamber in the centre. The rest is solid.

mouldings and ornaments in the interior of the villa of Hadrian, though in themselves classical and elegant, are small, and have a general air of littleness, especially when compared with the apartments to which they belong,—not that the apartments are generally large, but they are for the most part lofty. The ceilings appear to have been formed by vaulting; there are no indications of windows, and none of stairs of any magnitude—so that the rooms must have been nearly, if not quite, open at one end to admit light and air; and the probability is that there were seldom apartments above the ground floor, though it is likely enough that terraces formed on the vaulted roofs were used for the purposes of recreation and pleasure. Of the floors, which were of mosaic, several are preserved entire in the museum of the Vatican; where also are deposited many fine specimens of ornamental sculpture in vases and candelabra, besides busts, statues, and groups in bronze, marble, porphyry, and granite, of various styles, remains of the noble collection Hadrian made during his progress through his extensive dominions, which have been found among the ruins of the villa.

In Pompeii we may see the domestic as well as public architecture of ancient Rome, although it must be remembered that Pompeii was a Greek colony, and that it was destroyed as early as 79 A.D. We have, therefore, probably to expect more Greek character than would be met with elsewhere.

The streets of Pompeii are very narrow, their average width being not more than 12 or 15 feet; frequently they are not more than 8 feet wide, and very few in any part exceed 20. The principal excavated street in the city, that leading from the Forum to the gate towards Herculaneum, and the street of the tombs, is, at the widest, 23 feet 6 inches, including two footways, each 5 feet wide. The streets are all paved with lava, and almost all have side pavements or footways, which, however, are for the most part so narrow, that, with few exceptions, two persons cannot pass on them. That the cars or carriages of the inhabitants could not pass each other in most of the streets, is proved by the wheel-ruts which have been worn on the stones, and the recesses made here and there for the purpose of passing. They are lined on both sides with small cells, which served for shops of various kinds; and they are strikingly like the ordinary shops in towns in the south of Italy and in Sicily at the present time (Plate XVII. fig. 1). They resemble these, too, in this respect, that there appear in very few cases to be accommodations in connection with the shops for the occupiers and their families, who must have lived elsewhere, as modern Italian shopkeepers very commonly do. They present no architectural decoration whatever; the fronts are merely plain stuccoed brick walls, with a large square opening in each, part of which is the door, and part the window, for lighting the place and showing the goods.

Whenever a private house or gentleman's mansion was situated in a good place for business (like the ground floor of many modern Italian noblemen's palaces), the street-front, or fronts, were entirely occupied with shops, a comparatively narrow entrance to the house being preserved in a convenient part between some two of them (Plate XVII. fig. 3). The door to this is sometimes quite plain, but at times is decorated with pilasters. When the site permitted such an arrangement, the entrance door being open, a passer-by could look completely through the house to the garden, or, in the absence of a garden, to the extreme boundary-wall, on which was painted a landscape or other picture. An arrangement, it may be observed, not unlike this, is common in some of the Italian cities at the present day; but the mansions being now built in stories, and the upper stories alone being occupied by the families, a merely pleasing effect is produced; whilst in the former, persons crossing from one apartment to another were exposed to view, and domestic privacy thus completely invaded, to produce a pretty picture. Inside the entrance passage, which may be from 10 to 12 feet in depth, there is a space, the atrium, generally square, or nearly so, on which different rooms open, that vary in size from 10 feet square to 10 feet by 12, or even 12 feet square; they have doorways only, and were probably used as sleeping-chambers by the male servants of the family. In the centre of this court there is a sunk basin or reservoir for receiving the rain, called the impluvium, rendering it likely that this was roofed over, with a well-hole to admit light and air, and allow the rain to drop from the roof into the reservoir. Connected with this outer court was the kitchen and its accessories. If the site allowed the second court to be placed beyond the first in the same direction from the entrance, the communication was by a wide opening not unlike folding doors between rooms in modern houses, generally with a space intervening, which was variously occupied; or a mere passage led from one to the other. The second or inner court is generally much larger than the first, and is for the most part a parallelogram, but variously proportioned. It forms a tetrastoön, being open in the middle and arranged with a peristyle of columns, colonnading a covered walk all round. On this the best and most finished apartments open; but they are of such various sizes, and are so variously arranged, that it is not easy to determine more than that they included the refectory, the library, and sleeping-rooms. Some of them, indeed, are such as must have been useless except for the last purpose; these, perhaps, were the apartments of the female branches of a family, at least in most cases. Some houses, however, have a nest of small cells in an inner corner or secluded recess, which may have been the gynæceum; but that is far from being common. Exhedræ or recesses, open in front to the atrium, are common, and are often painted with more care and elegance than any other part of the house; but generally the walls are everywhere painted—in the more common places flat, with a slight degree of ornament, perhaps, and in the best rooms, with arabesques and pictures in compartments. The architectural decorations are mostly painted; the ornaments are not unfrequently elegant, but the architecture itself of the mansions is bad in almost every sense. The rooms being windowless, would, when covered, be necessarily dark; the doors are arranged without any regard to uniformity, either in size or situation. The street-fronts of those houses which, not being in a good business situation, were not occupied with shops, were not merely unadorned, but were actually deformed by loop-holes, to light some passage or inner closet which had no door on one of the courts. (Plate XVII. fig. 8.) The columns of the second courts are generally in the worst style possible: those which have foliated capitals, and may be considered compositions of the Corinthian order, are the best; but the imitations of Doric and Ionic are both mean and ugly. From the uses to which they were put, and the wideness of their intercolumniations, together with the fact that none of them have been found in Pompeii, it is probable that the entablatures were of wood, and were consequently burnt at the time of the destruction of the city, and broken up by the inhabitants, almost all of whom certainly escaped, and who, it is very evident, returned, when the fiery shower and the conflagration had ceased, to remove whatever they could find of their property undestroyed; for it must be remembered that the roofs and ceilings all over the city are entirely gone, and the uncovered and broken walls remain, from 8 to 10 feet only in height. Everything, indeed, clearly demonstrates that great exertions were used

to recover whatever was valuable; and it is very probable, moreover, that the place was constantly resorted to by treasure-seekers for perhaps centuries after the calamity occurred. It may also be remarked that the loftier edifices, which would have been unburied by the ashes, had been thrown down by an earthquake about sixteen years before the volcanic shower fell, and, therefore, were the more easily covered. Other showers must have fallen since that which destroyed the city, to produce the complete filling up of every part and the general level throughout. Hence we are still uninformed as to the structure and disposition of the roofs and ceilings of the houses of the ancients. The doors, too, of whatever materials they were composed, are entirely gone: there remain, however, here and there indications—and even charred fragments—of wooden door-posts, but they belong to outer or street doors, leaving it probable that a matting of some kind, suspended from the lintel, formed the usual doors to rooms. It is, in fact, supposed that curtains answered the purposes of doors to the interiors. In these particulars, unfortunately, Herculaneum affords but little assistance, as the mode of its destruction was similar to that of Pompeii, though, upon the whole, Herculaneum is more likely to furnish information on these particulars than its sister in misfortune. Although it has been ascertained that the Romans understood the manufacture of glass, it must not be supposed that they were accustomed to apply it as freely as we do to exclude the weather and transmit light. It was, however, sometimes used; one wooden frame with four small squares of glass has been found; another brass frame with the glass movable; and one piece of glass of considerable size was found in one of the walls of a bath. The floors of the houses of Pompeii and Herculaneum are all of mosaic work, coarser and simpler in the less important parts, and finer and more ornate in the more finished apartments: the ornaments are borders, dots, frets, labyrinths, flowers, and sometimes figures. In this, too, the superior advantages the moderns enjoy are evident. The ancients did not understand how to construct wooden floors, or, at least, they did not apply timber to that use. A few rude and narrow staircases are found in Pompeii, which, it is very probable, were to afford access to the terraces or flat roofs, for they are not common, and no portion of an upper story remains in any part. Sufficient remains have, however, been found to show that the upper stories often overhung the lower front, as in mediæval houses; the fronts being made of woodwork, supported on a prolongation of the floor joists. In one part of the city the houses on one side of the street are on a declivity: there a commodious flight of stairs is found to lead from the atrium in front to another lower court and rooms, not under the houses but behind them; for we do not find an under-ground story in the Pompeian houses. On the shores of the Bay of Baiæ, and at Cicero's Formian Villa on the Gulf of Gaeta, however, there are crypts or arched chambers under the level of the mansions, the sites requiring substructions; but it may be questioned whether even these were used as parts of the house, and as we use cellars, for they present no indications of stairs, and have no regular means of intercommunication.

Numerous remains of Roman houses are found in all the colonies, and notices of many in England will be found in the *Archæologia*, and other archæological publications. They are not of sufficient importance to be quoted here, but they serve to show that the Romans carried with them into other lands the same habits, and even practised the same mode of construction which they adopted at home. One very remarkable exception exists, viz., in the Hauran in Syria. The edifices there were first, we believe, noticed by Humboldt. They have since been described in detail by Mr Cyril Graham and others, and have been admirably illustrated by Count Vogüé. The country was conquered by the Romans at the end of the 1st century A.D., and the houses, &c., seem to range in date from that time, or, perhaps, earlier, to the end of the 4th. They are contained within stone walls, forming small towns, and so numerous that sixty of these walled cities have been counted, all now desolate, but in many cases remaining almost perfect even to the doors, shutters, and paving of streets. The remains are chiefly of houses whose walls are of basalt. The rooms are 12 to 20 or 25 feet square, with strong, arched ribs thrown across, supporting a ceiling of thick slabs of basalt. Some of these are as much as 18 by 12 feet, and 6 inches thick. The doors and shutters are of the same material, often panelled as though of wood. A specimen of these, and also some of the carvings, are in the British Museum.

BASILICAS.—We have left these to the last, as they are more intimately connected than any other ancient architectural forms with those of the Christians. They seem to have been at first much the same class of building as our Royal Exchange, both as regards use and plan; open in the centre, with porticoes round. Then all was roofed over, and a sort of triforium or gallery formed over the porticoes. At one end was a recess, often circular and parted off from the rest by a screen of columns. This, with the space in front of it, formed the Tribunal. In Trajan's, there seems to have been an apse at each end. Remains are found at Pompeii and Herculaneum, Treves, &c. A complete exception to the ordinary form is found in the Basilica of Maxentius (formerly known as the temple of Peace) at Rome. Basilicas

RÉSUMÉ.—Roman architecture, as we know it, dates only from about the Christian era, and the rapidity with which it spread from that time is something marvellous. Through nearly the whole extent of the Roman empire, through Italy, Asia Minor, Sicily, Britain, France, Syria, Africa,—with one great exception, Egypt,—all was Roman in mouldings, ornaments, details, the very style of carving and the construction. No matter what the country or the architect, all seem to have lost their nationality when the Roman came, and to have adopted implicitly his system of design and decoration. It has been seen that he copied the orders and much of the leading forms of his buildings from the Greeks. But he speedily added others. The apse and the circle on plan were his; so were the dome and the arch in elevation; and thus he enlarged at once the whole range of the architect's powers, and whilst utterly disregarding the delicate refinements of the Greeks, secured a freedom of design which resulted at length in our Pointed architecture. Résumé.

But great as the advance was, it seems to have been arrested just when opportunities were offered, on the grandest scale, for bringing about the noblest results. The Roman architect seems to have been unable to reach the highest effort of art, viz., to bring the whole of any grand edifice into one splendid mass, to concentrate the detailed parts into one grand whole. But in reflecting on what the Roman did *not* do, we must not forget that we owe to him some of the grandest forms to which we too are now accustomed.

We now come to a complete change in the structures which we have to describe. Henceforth we shall find no Forum, no public bath, theatre, temple, or house. All these forms disappear, and for nearly 700 years, until the time when the Norman castle arose, well-nigh every building of architectural merit was in some way or other ecclesiastical. But with our Christian faith there arose forms of beauty utterly unknown to the Pagan, which culminated in the glories of Lincoln and Canterbury.

POINTED ARCHITECTURE.

In those countries which received the Christian religion from Rome, but which did not contain such mines of architectural material in temples, amphitheatres, and palaces, as Italy did, and, indeed, in the remoter parts of Italy itself, which did not contain them as Rome did, churches were constructed in imitation of those of the metropolis of the Christian world. These being the work of a semibarbarous and unpolished people, were of necessity comparatively rude, and from them arose the Gothic architecture of the Middle Ages,—not from any previously existing style of architecture among the northern nations who overran Italy and subverted the Roman power, the rude Celtic monuments being the only specimens of architecture they possessed. The transitional style of architecture referred to will be found in what are called the Saxon and Norman buildings of England, and to a greater or less extent in all parts of Europe in which the Romans had been masters, and particularly in those which adhered to the Roman communion in the great division of the churches. The general forms and modes of arrangement peculiar to Roman architecture may be traced throughout; in some specimens they are more and in others less obvious, but the leading features are the same. This is more evident in Italy than elsewhere. In the early Roman basilicas and churches, some of which are of the age of Constantine, and which were constructed in the Roman style, the first divergencies occur; in those which are later they are still greater, and distance of time and place appears still to have increased them, till what may be called a new style was formed, having peculiarities of its own, but even more clearly deducible from its origin than Roman is from Greek or Greek from Egyptian. The variation in the development from the parent stock is great, but in all cases there is more or less evidence of the descent. It must be noted, however, that there was one important modification of Roman art, and this was the Roman art modified by contact with the East, and known commonly as Byzantine. Its influence was felt first and most strongly in St Mark's, Venice, a building which is entirely Byzantine in style as opposed to Romanesque. From Venice it was copied in Périgueux in the church of St Front, and this copy influenced the style of a vast number of buildings in the south-west of France. St Mark's, again, had a great influence on the Lombard works of Northern Italy, and these were the originals from which Germany, by way of the valley of the Rhine, derived all its mediæval buildings. To the greater part of France and to England the stream of art was much more purely Romanesque, being the result of knowledge of genuine Roman art, with little, if any, influence from the East In Spain we see the direct influence of the Romans, the direct influence of the Arab, and the indirect Byzantine influence of the south-west of France, all materially affecting the development of the national architecture. As might be expected, this style was not the same in all the countries which practised it; it was derived, in them all, from the same source, as we have shown, but was materially influenced by the habits, manners, and state of civilisation of the various nations, and much, too, by their means of communication with Rome. This, in strictness, may be called Gothic architecture, as it was partly induced by the Gothic invasions of Italy, and was invariably practised by the nations to whom that term may with propriety be applied. It arose in the 4th century, and was subverted in the 12th by the invention or introduction of the pointed arch, which marks a new era, and was destined to give birth to a new style in architecture.

Where, when, and with whom the pointed form originated has been more discussed and disputed than the discovery of the properties of the arch itself. Some have contended that it was suggested by the intersections of semicircular arches, as they were employed in ornamenting the fronts of edifices in the preceding style; some, that groined arches of the same form gave the idea; others have referred it to the interlacing of the branches of trees when planted in parallel rows,—to an imitation of wicker-work,—to a figure used on conventual seals,—to the principle of the pyramid,—to Noah's ark,—to chance. Such a mass of conflicting opinions, almost all supported by some show of reason, and more or less by evidence, may be called a proof of the impossibility of determining the question. There is one striking fact, however, which has been overlooked by many of the theorists in the discussion of the question; it is, that the pointed arch made its appearance almost at the same moment of time in all the civilised countries of Europe. This is proved by the controversies of those who claim its invention for their respective nations; for none of them can produce genuine specimens of it before a certain period, to which they can all reach. Now, if it had been invented in any of the European nations, that one would certainly have been able to show specimens of it of a date considerably anterior to *some* of the others; for though it might by chance have been soon communicated to any one of them, the improbability is great that it would immediately have reached them all, and have been at once adopted by all, to the subversion of their previously practised forms of construction. The infrequent and imperfect modes of communication between the different countries of Europe at the period referred to, furnish another reason why it is not probable that a discovery of the kind should travel rapidly from one to another. Considering these things, and particularly the fact of the almost simultaneous introduction of the pointed arch to the various nations of Europe, as it appears by their monuments immediately after the first Crusade, in which they all bore a part, connected with existing evidence that it was commonly used in the East at and anterior to that period, the most rational and satisfactory theory seems to be that a knowledge of it was acquired by the Crusaders in the Holy Land, and brought home to their respective countries by them. In Europe there are found rude approaches to the pointed form in some of the earlier Gothic structures; but we believe it may be safely asserted that nothing can be indicated of a date beyond that of the first Crusade, approaching the simple but perfect lancet arch, which, it is not denied, came into use immediately after that period; whereas tolerably well-authenticated examples of it are found in the East, of sufficient antiquity to induce the opinion that it was at that time imported thence. It is, moreover, indisputable that the Saracenic or Mahometan nations, who were never known in those times to adopt any European custom or invention of any kind, do use, and have used, the pointed arch. It was very extensively employed in various parts of Asia, and nowhere in more sumptuous edifices or with greater effect than in the structures erected by the Mahometan conquerors of India. With what nation of the East, and in what manner, the pointed arch originated, are problems equally difficult to solve. We have not been able to discover that the properties of the arch were known to the Egyptians or to the Greeks, and there is no evidence to show that they were known to the Persians or to the Indians of ancient times; but structures are found in the countries of those nations in which chambers are domed, and apertures covered with a pointed arch, produced, however, by gathering or corbelling over, and not by arched structure. It is not improbable, therefore, that, such things existing, when the properties of the arch became known, that form would be repeated upon it, and the result would be the lancet arch,—the prototype, the germ of the style. The pointed arch, on its introduction into Europe, was not accompanied by any of its ordinary accessories in after-time,—its light clustered pillars, its mullions, foliations or featherings, and graceful tracery. These developments resulted from its adoption; so that whether the arch itself was invented in Europe or imported from the East, to the European nations must be assigned the credit of developing the beautiful style of architecture whose distinguishing feature it is.

Before proceeding further with this subject, it is necessary to determine by what name this style is to be designated. There have been only too many arguments and discussions on the name which is most appropriate to the style. By common consent the word Gothic is used all over Europe to designate it, and it now hardly matters whether or not there was originally good reason for the use of such a term. One of the first in England to use the term was Sir Henry Wotton. It was continued by Evelyn, who applied it more directly; and the authority of Sir Christopher Wren finally settled its application. But they used the term as one of reproach for what they thought a savage and uncivilised sort of art, though it was in vain that, by the use of a bad name, they attempted to deny the merit of that which was after all the only nationally developed style of their own country as well as of the whole of Northern Europe. In the last century, through the influence and enthusiasm of Horace Walpole, and afterwards of John Carter, an eminent artist and architect, a better taste was formed, and this led to the appreciation of that which is, indeed, the English national style. Many attempts were made to explode the totally irrelevant appellation of "Gothic" which had been applied to the style, but without effect. Some writers have called it Italian, others German, others Norman or French, others British, and many have contended for the exclusive term English. To this last the Society of Antiquaries lent its influence, but with equal inefficiency, for the term Gothic still prevails. Mr Britton, than whom perhaps no man possessed a greater right to affix an appellation to the pointed arch style, from the splendid services he has done it in the publication of his *Cathedral and Architectural Antiquities*, wished to introduce a term which is not at all unlikely to succeed, as it is equally appropriate and independent of national feeling and hypothetic origin. He called it Christian architecture, and in this he was followed by the younger Pugin and many others. This, as a generic term, would admit each nation possessing specimens of it to distinguish its own species or style; and as the varieties of Hellenic architecture are known by the names of the tribes or nations who are presumed to have originated them,—Dorian, Ionian, and Corinthian,—so might Christian architecture be English or British, German, French, &c., for each has its peculiarities. These species would again individually admit of classification, according to the changes each underwent in the course of its career. One objection, however, has been taken to Mr Britton's distinctive appellation. It is, that "Christian" applies as well to what may also properly be called the Gothic style—that which arose on the extinction of Roman architecture, and was subverted by the introduction of the pointed arch, and which, indeed, owed its diffusion and progress, if not its origin, to the Christian religion. We are therefore still left to seek a suitable appellation; and in the absence of a better, are inclined to use the term Pointed, which is not only distinctive, but descriptive; it has, too, the merit of being general, so that it may mark the genus, while the national species and their varieties may be distinguished by their peculiarities as before.

The pointed arch was a graft on the Romanesque, Lombard, and Byzantine architecture of Europe, just as the circular arch of the Romans had been on the columnar ordinances of the Greeks; but with a widely different result. The amalgamation in the latter case destroyed the beauty of both the stock and the scion; while in the former the stock lent itself to the modifying influence of its parasitical nursling, gradually gave up its heavy, dull, and cheerless forms, and was eventually lost in its beautiful offspring, as the unlovely caterpillar is in the gay and graceful butterfly.

We all know that architecture has had its origin in religious feelings and observances—that its noblest monuments among the pagan nations of antiquity were temples to the gods—whilst the rude nations of the north in the Middle Ages devoted their energies, after their conversion to Christianity, to the construction of suitable edifices for the worship of the Almighty; and we find, again, that the most extensive and most splendid structures raised by the same people, when the light of learning had begun to shine upon them, and a new and more beautiful style of architecture had been developed, were dedicated to the same purpose. In addition, however, many, hardly less magnificent, and not less beautiful, were raised for the purposes of education, and became the nurseries of science and literature. Kings and nobles also employed architecture in the composition, arrangement, and decoration of their palaces and castles; and though for domestic purposes its aid was not so largely required, it was equally used. The remains which have come down to us from the earlier portion of the Middle Ages are comparatively small, but there is ample evidence to show that the style was universal in its application, and so full of life and vigour that every implement, every piece of furniture, and every detail of dress or ornament, was governed then, just as in the best period of classic art, by the rules of art which were observed in the largest and stateliest of the public buildings of the time.

When the practice of building houses in stories commenced cannot be correctly ascertained, though it was usual among the Romans, as we know by the example of Pompeii, and it appears to have been usual during the Middle Ages. We frequently, indeed, find an apparent equivalent for the term *story* used by the ancient writers, both sacred and profane; but it must be remarked that none of the ancient remains, whether of public or private structures, afford evidence that it was a common practice even among the Romans to build more than one story above the ground floor; and it was less likely to be common among the Eastern nations, with whom the practice is not very general, even at the present day. Indeed, without considerable proficiency in the art of construction, it is hardly practicable to erect buildings in stories with such slight materials as were used by the Romans in some of their domestic edifices. We find, however, in the oldest existing works of the Middle Ages, and particularly in some of the secular structures of Venice, a degree of intelligence evinced in this respect far surpassing anything found in ancient remains. Possibly the skill was principally acquired in that city from the necessity of making artificial foundations, which consequently required a superstructure not unnecessarily cumbrous; and again, to make slight walls sufficiently strong, they must be skilfully bonded in themselves, and bound together, which could only be done by means of a material possessing considerable length and great fibrous tenacity—whence arose framed floors of timber. These, by their strength, their obvious utility and convenience, added to the want of space which existed in a thriving and populous community on a very restricted spot of dry land, superinduced, in the second place, the building of additional stories, which would soon be imitated in other places. But in whatever manner the improvement took place, the fact that it was made is certain; and we find it applied in all the works of the European nations, both ecclesiastical and civil, from the 9th and 10th centuries downwards. The combination of masonry and carpentry in building tended greatly to the advancement of both; for, it being required at times to make them act independently of each other, additional science and art were necessary, as the proportions must be retained that were given to similar works in which they co-operated. To this is to be traced the skill displayed in the vaulted roofs and ceilings, in the towers and lofty spires of some of our Pointed cathedrals for the one, and such splendid examples of construction as the roof of Westminster Hall for the other. On this point Sir William Chambers, who was certainly no depreciator of the merits of the Romans in architecture, says: "In the constructive part of architecture the ancients do not seem to have been great proficients" (Gwilt's *Chambers's Civ. Arch.*, p. 128); then having referred many of what he calls the "deformities observable in Grecian buildings" to want of skill in construction, he continues, "neither were the Romans much more skilful; the precepts of Vitruvius and Pliny on that subject are imperfect, sometimes erroneous, and the strength or duration of their structures is more owing to the quantity and goodness of their materials than to any great art in putting them together. It is not, therefore, from any of the ancient works that much information can be obtained in that branch of the art. To those usually called Gothic architects we are indebted for the first considerable improvement in construction. There is a lightness in their works, an art and boldness in their execution, to which the ancients never arrived, and which the moderns comprehend and imitate with difficulty. England contains many magnificent specimens of this species of architecture, equally admirable for the art with which they are built, the taste and ingenuity with which they are composed." To this Mr Gwilt, in his edition of Sir William's work, adds, with much truth, in a note, "There is more constructive skill shown in Salisbury, and others of our cathedrals, than in all the works of the ancients put together."

Pointed architecture took root and grew with almost equal vigour, though under different conditions, in almost every part of Europe. But the honour of having developed the style to the very highest perfection must undoubtedly be adjudged to France, or rather to the small portion of the country, including Paris, which formed the old Ile de France. In Germany there was much less natural development. For a long period after the Lombard style had been perfected on the Rhine no variation of moment was adopted, until German architects attempted at Cologne to outvie and rival the magnificence of Amiens. In Spain the architects of some of the finest buildings were Frenchmen, and the style can hardly be said to have been developed there at all. In England, on the contrary, though our earliest Pointed buildings were undoubtedly to a great extent French in their origin, the developments of the art were soon entirely national, and were but little modified even by the influence of the foreign religious orders, which (as at Fountains Abbey) had so much power over many of our ecclesiastical foundations. From England the style was carried by Englishmen to Scotland,—a poor country, with no style of its own, and no cultivation such as is necessary to produce an order of architects, and to Ireland, where the English architects followed the footsteps of the invading armies; and finally, if we may trust the evidence of the stones themselves, to the coast of Norway, where the cathedral of Trondhjem is as unmistakably English in much of the style and detail as any English cathedral. In England the development of the style is plainly marked, and its advances are easily traceable. We find in various portions of the same edifice, according to the period of its construction, exemplifications of the style, from the ingrafting of the simple lancet arch on the Norman piers in the time of Henry II., to the highly enriched groinings and ramified traceries of the age of Henry VII.; but the changes are so gradual, and are so finely blended, that the one in advance appears naturally to result from that which comes before it. Although the nations of the Continent never borrowed from us, but were themselves originators, it is very clear that after the first we did not borrow; for our structures bear the strongest possible marks of originality, as the gradual advances can be traced from one feature to another in a way which is quite peculiar to this country. This, however, will be explained more in detail further on.

The Pointed Architecture of Europe generally.

There are so many local and national varieties of this style that it is quite impossible to dismiss it with an account of its features in one district or country only. To do this would be to give an entirely wrong and inadequate conception of the subject. It must be treated generally under the heads of the several countries in which it has flourished most—as England, France, Germany, and Spain. It must certainly not be forgotten in talking of Italy. And in most of these countries it might properly be subdivided according to the local varieties caused either by changes in the political geography, or by physical conditions which so largely affect the details and variations of style in architecture. For the origin of all these developments of the style we must go back to Rome. It is not only that in the Roman states we see the origin of Romanesque architecture gradually developed out of the Roman buildings. The same process was going on at the same time all over Europe wherever the Roman empire extended. We have only to look at the Roman occupation of the south of France, as evidenced by the still magnificent remains of theatres and tombs at Arles, of the amphitheatre at Nismes, of the theatre at Orange, or the aqueduct of Pont de Gard; or at the similar works on the coast of Spain, at Tarragona, or in its very centre at Segovia; or at the basilica, gateway, and theatre at Treves; or in our own country at the remains of Roman buildings in various directions, of which Silchester is surpassed in interest by none;—we have only to look at all these in order to see that, erected as they were in countries which at the time were little better than barbarous, they must of necessity have prepared men all over Europe for the same sort of development. The Romans had shown them the use of the arch, the column, and the vault; the conversion to Christianity gave them a great want to satisfy; and finally, the revulsion of feeling when the supposed mystical year of our Lord 1000, with all its apprehended accompanying dangers, had passed in safety, gave such an impetus to buildings for religious purposes as the world had never before seen. It was a time for development, therefore, and nearly everywhere the development proceeded from the same premisses. Roman art, pure and simple, was the general foundation of all Romanesque building, and it was only slightly modified in certain districts by the introduction of the Byzantine influence from Constantinople to Venice, and thence in some degree to some other cities and towns, or, as in Pisan buildings, and in those of the south of Italy and south of Spain, by the Greek and Arab influence which was so great down to the end of the 13th century. An examination of the earliest European churches—such, for instance, as San Clemente and San Lorenzo at Rome—will show how entirely they were constructed on Roman models. From them we go in Italy to Ravenna or Toscanella, to

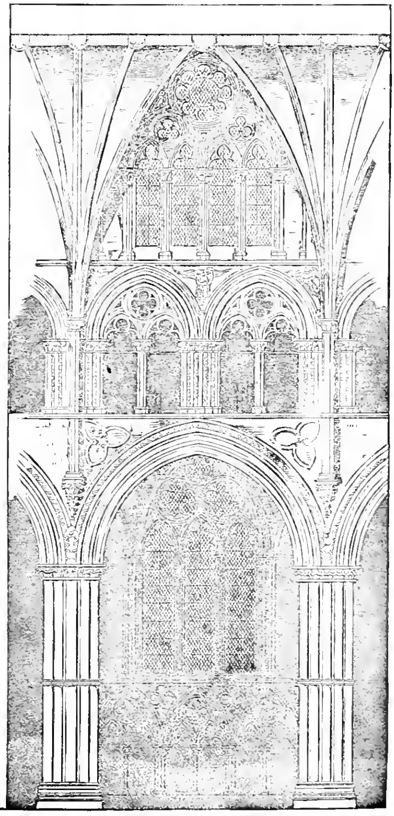

Fig. 2.

San Miniato at Florence, to the cathedral of Torcello, to San Zenone, Verona, and San Michele, Pavia, and see how gradually but surely the plan and details were being developed into what soon became a new style; and from these examples we may follow the stream of art from the south to the centre of France, and thence to this country and Germany. Or looking at other developments in Italy, we may in the same way trace a succession of circular buildings, in which the connection and sequence is clear, leading us as it does from the Pantheon, and other circular Roman temples, through the old cathedral of Brescia and the grand church of San Vitale, Ravenna, to the cathedral at Aachen, and so to our own circular churches, and to many of those which, like the Marien Kirche, Treves, though not really circular in appearance, are yet so planned as to fall properly within the same class.

The course of progress of European art was to a great extent first of all geographical and political. For, in addition to the influence exercised by conquest or the political connection of one district with another, it is remarkable how much particular styles are limited by geographical divisions and boundaries, by the courses of rivers, the occurrence of convenient building materials, and other such secondary causes. And with so many causes for variations of style in existence, it will be quite necessary, in order to give any intelligible account of the whole course of Gothic architecture, even in the shortest compass, to treat separately each of the great national divisions. We will take England first, only premising that, following strict order, we ought to have begun with Italy, were it not that, in spite of the origin of all northern art having to be looked for there, as soon as it came to be a question of development, almost all the life and vigour of architecture in the Middle Ages is to be seen north and not south of the Alps; and whatever was borrowed, in the first instance, from Italy was paid back again with interest afterwards. And in taking England first, we have the advantage of speaking of a national art, of which every educated Englishman knows some of the examples, so as to be more able to follow the course of our argument than would be the case were all the examples of its application foreign and unknown to him.

English Gothic Architecture.

The history of the development of Gothic architecture is, perhaps, more easily read on the buildings themselves here than it is in any other part of Europe. The Roman buildings in England were never of very great importance, and were not always standing as evidences of the existence of an older style, which might be looked back and up to with respect and admiration, even where they did not harmonise with popular customs. Such art, nevertheless, as did exist in this country before the 11th century, was, no doubt, derived from Roman examples existing in the country, and copied in a rude and unskilful fashion by native workmen. The existing Roman remains show that there was quite enough architectural and decorative art introduced into the country by the Romans to have formed a school of masons, sculptors, and builders, if the civilisation of the people had been sufficient to make them desire it. Such a school can hardly be said to have been formed if we look at the few and comparatively rude remains of buildings certainly erected before the Norman Conquest. In such work as the beautiful archway recently discovered in Britford church, Wilts, where carving of stone-work is joined with brick or tile and stooc in a very elegant fashion, we see the immediate effect of cultured Roman influence and example. At a later date, in such fine works as the steeple of Earl's Barton, Northants, we see only the rude grandeur of comparatively uncivilised workmen cognizant only at a distance of good Roman work. In upwards of a hundred churches, dispersed in various parts of England, fragments more or less complete of these early buildings, erected before the Norman Conquest, still remain. They are numerous enough to enable us to classify their features in a general way, and they agree in certain definite points of difference from the architecture which prevailed after the Norman Conquest. It is probable that a considerable proportion of these buildings were erected after the year 1000, when we recollect the influence which the expected end of the world had in discouraging building shortly before that date, and how enormous the zeal for building was as soon as it was safely passed. The leading features of the buildings erected before the Conquest are as follows:—(*a.*) Quoins at angles alternately long and short, the difference being so marked as to be seen on the most casual inspection; (*b.*) Arrangement of wall faces into panels by means of vertical strips or pilasters of stone; (*c.*) Arches built not only in semicircular form, but frequently (and especially for arcading) with straight sides; (*d.*) Rude balusters, generally bulging outwards in the centre, used to divide openings of more than one divison (as, *e.g.*, belfry windows); (*e.*) Introduction of rudely moulded, chamfered, or plain square abaci at the springings of arches; (*f.*) Towers, in several cases of some importance, adorned with arcading, formed by pilasters and round or straight sided arches. These features are all represented in illuminated MSS. of the same period, and are not seen in works executed after about the date of the Conquest. It is this fact that makes the year 1066 a convenient year for dealing with as the assumed commencement of a new epoch. But in fixing this date, we must remember that, though the Conquest of William would account satisfactorily for the changed style of building which is universally seen after this time, there can be no doubt that Edward the Confessor's Norman education led naturally to the introduction of many Norman features into English work. The considerable remains of that king's foundation at Westminster Abbey afford good evidence of the fact, that the so-called Saxon style had been abandoned by the workmen employed by him, and that the way was being prepared for the adoption of all the Norman architectural features even before the imposition of the Norman rule.

The succeeding periods of English architecture have been generally divided upon similar systems, the main dispute among antiquaries and architects being as to the nomenclature of the various styles which followed each other in a regular course of development, rather than as to the exact period of change. Between the complete styles there is always a period of transition, during which the features of the styles were not so well marked, and during which the progress of the art was by no means uniformly rapid in all parts of the country. The following chronological table gives the main divisions:—

	Style.
From the reign of William I. to the end of Stephen, 1066 to 1154	Norman; or Romanesque.
Henry II., 1154 to 1189	Transitional from Norman to Pointed.
Richard I. to Henry III., 1189 to 1272	Early English; First Pointed; or Lancet.
Edward I., 1272 to 1307	Transition from Early Pointed to Complete, or Geometrical Pointed.
Edward II., 1307 to 1327	Geometrical Pointed.
Edward III., 1327 to 1377	Flowing; or Curvilinear Style. These two are generally treated as one style, called by Rickman Decorated, by others Middle Pointed.
Richard II., 1377 to 1399	Transition from the flowing lines of Decorated or Middle Pointed to the stiff and hard lines of the succeeding style.
Henry IV. to Henry VIII., 1399 to 1546	Third Pointed; or Rectilinear (Sharpe); or Perpendicular (Rickman).

Even after this period many buildings were erected in a debased imitation of Gothic, but their features do not admit of their being classified with the same precision as those which obtained from about the year 1066 to 1546. For that period of just 500 years so regular was the development, that it is not too much to say that a well-informed architect or antiquary ought always to be able to give, within ten or at most twenty years, the date of any, however small a portion of mediæval architecture, with almost absolute certainty of being correct when his judgment can be tested by documentary evidence. With this preface we will now describe, in as concise a manner as possible, the features of the various divisions given in the foregoing table.

Norman. The characteristics of the Norman style are, no doubt, generally known. The works executed during this period were on so colossal a scale, and so many of them are still perfect, that every opportunity is afforded for studying them in all parts of England. It may be observed, too, that there is less variety in the character of the style in different dioceses or counties than there is in the case of subsequent works. The earlier works, as, *e.g.*, Walkelyn's transepts at Winchester Cathedral, are comparatively simple and rude. The arches are unmoulded, the capitals are of the simplest form of cushion capital; and grand and solemn as the work is, it cannot, for refinement and beauty of detail, be compared to the later Norman work in which, instead of minute directions being given to the workmen, they were encouraged to develop their own taste and ingenuity in the decorative sculpture with which they so elaborately covered their architectural mouldings But still, the principles of construction, and of the decoration of it, were identical throughout the whole period. The ground-plan of most Norman churches was cruciform, with a central tower, the east end being very frequently apsidal. The aisles were divided from the naves by columns of vast size, sometimes circular, sometimes octagonal, and sometimes simply clustered The arches were for the most part semicircular, save towards the end of the period when the pointed arch was often used where much strength was required, though the round arch was still used everywhere for ornament. The windows in small buildings were mere narrow slits in the wall, probably not meant to receive glazing, and opening out with a wide splay on the inside; in larger buildings they were much more important features, being of large size and adorned with columns, with capitals and bases both inside and outside. The treatment of mouldings was accurate and scientific. As large arches are naturally constructed with a series of orders or layers of stones, the masons wrought each of these with a separate moulding, so as to define them well, and provided capitals whose upper surface was ingeniously planned, even where it fitted a circular column below, so as to fit exactly the several orders of the arch. This is one only out of many features which prove how skilful the Norman architects were. All their best works are in no sense haphazard works of art, but carefully ordered and arranged with almost classic attention to regularity. The masonry is at the same time unusually beautiful and well executed. There is probably not a finer piece of masonry in England than the late Norman central tower of Winchester Cathedral,—the stones being all uniformly wrought, close jointed, and regularly coursed. The doorways are the great glory of many of these buildings. Sometimes the mouldings are continuous round jamb and arch (as in the well-known examples at Malmesbury Abbey and at Iffley), but more usually they are adorned with a series of columns, sometimes carved or diapered, and carrying on their capitals a grand succession of enriched arch mouldings. These doorways do not occur only in large and important churches, but are to be seen also in out-of-the-way country churches in all parts, even the most remote, of England. The walls were often arcaded with single or intersecting arches, treated in the most elaborate manner. They were usually of so great a thickness that no buttresses were required, even where, as in the aisles of large churches, stone vaulted roofs rested against them. The Norman buttress, wherever introduced, is consequently only a slight development of a pilaster, used for the purpose of defining the divisions or panels of an elevation, and not introduced for the sake of giving support to the wall. The walls are frequently enriched with moulded or carved string-cornices, and with a cornice supported on corbels under the eaves of the roof, and in the best works are entirely of wrought stone, and built in regular courses. The roofs which surmounted the walls were usually of steep pitch, showing the whole of the cross framing of the timbers used in them; and sometimes, as in the case of Peterborough Cathedral, boarded on the under side so as to form a flat or slightly canted ceiling, which was then decorated with colour. At Adel, near Leeds, are remains of a richly-moulded Norman roof, in which every pair of rafters seems to have been furnished with a tie-beam. But it need hardly be said that not many wooden roofs of this period exist; and the stone roofs which, as time wore on, were more and more often erected, were not only more permanent in their character, but, no doubt, played the most important part in the gradual development of the style and the introduction of the pointed arch. The succession of vaults was the same here and on the Continent. First of all the plain barrel vault, then one formed by the intersection of two such vaults at right angles; and finally, this vault with well-defined arches between the bays, and mouldings or ribs under the angles of the intersecting vaults. It was impossible for men to go on long forming such vaults as these without realising, not only that a pointed arch might be built, but, at the same time, that its form enabled a builder to overcome many practical difficulties in the formation of vaults, which could only be got over otherwise, and then badly, by the expedient of stilting the round arch. The Norman vaults were seldom applied to any but the aisles of churches at no great height from the ground. They were very heavy, and exerted more thrust on the wall than the later Gothic vaults, and the Norman masons shrank consequently from venturing to put them on their lofty clerestories.

Transition to Pointed. It was in the next period—that of the transition to Pointed—that the science of vaulting received a great impetus, whilst the whole architectural construction at the same time tended to assume more graceful and elegant lines. In so general a view of the case as this, it is impossible to do more here than point to salient examples which illustrate generally the progress of the art. Just as the cathedrals of Peterborough, Durham, Norwich, and Ely illustrate, on the grandest scale, the features of the best Norman art in England, the eastern part of Canterbury illustrates the whole period of the transition from that to Pointed, and is consequently one of the most valuable buildings that we have for the purpose of study, as well as one of almost unrivalled beauty and magnificence. Professor Willis has made this church classical ground to the archæologist who, under his guidance, and with the advantage of the description of the work written by the monk Gervase, who saw it in process of building, examines its many curious evidences of gradual development. Gervase himself describes the changed mode of workmanship and design, as he chronicles the difference between the new work and that older Romanesque choir which had before his time been called "the glorious choir of Conrad." He says,—"The pillars of the old and new work are alike in form and thickness, but different in length; for the new

SCALE. 20 60 80 FEET

PISA CATHEDRAL. (West Front)

pillars were elongated by almost twelve feet. In the old capitals the work was plain, in the new ones exquisite in sculpture. There the arches and everything else was plain or sculptured with an axe and not with a chisel, but here almost throughout is appropriate sculpture. No marble columns were there, but here are innumerable ones. There, in the circuit around the choir, the vaults were plain, but here they are arch-ribbed and have key-stones." "There was a ceiling of wood decorated with excellent painting, but here is a vault beautifully constructed of stone and light tufa. There was a single triforium, but here are two in the choir, and a third in the aisle of the church," &c. This great work was begun under a French architect, William of Sens, in the year 1175; he was killed by injuries received in a fall from the scaffolding in 1179, and was succeeded by his assistant, William the Englishman; and to these two men is due the credit of the design as we now see it. One of the most noteworthy points in its history is the obvious and simple mode of accounting for the French character and state of much of the work, which it presents; and looking at it, no one can be surprised at the enormous development which immediately took place throughout the country. The change from heavy piers, with carving rather elaborate than beautiful, to delicate columns carrying on exquisite capitals lofty and graceful pointed arches and vaults, was so great that it was impossible not to prefer it to the stately but comparatively rude work which it supplanted; and so the tide of change having set in, further improvements were soon desired. Mouldings became much more delicate and subtle in their contour. Groining was then more tastefully planned and disposed, windows and doorways were made far more graceful, whilst the system of construction was largely improved upon. Instead of thick, massive walls without buttresses, the walls were reduced in thickness, and the material saved was transferred to the buttress, where it could most effectually fulfil its office of supporting the vaults and walls above. From buttresses conceived in this view the transition to flying buttresses was easy; then to stiffen these, pinnacles were added. And in the same way one lancet window led the way to groups of lancets; and these in their turn by combinations with pierced circular windows, to completely developed traceries.

First Pointed. The First Pointed, Lancet, or Early English style to which the transitional work thus led up, may fairly be considered to be a purely English variety of Gothic. It is more consistently graceful and delicate in its details, as well as in its general character, than any foreign work of the same period. There was no longer any observable foreign influence brought to bear as there had been at Canterbury. Intelligent artists all over the country were rapid in seizing the best features of executed works, and carrying them farther with as little delay as possible. There were various centres from which distinct local varieties of style were sent out. If we compare York (transepts), Lincoln, and Salisbury Cathedrals, we shall find that, though there are certain general similarities of treatment, the distinct mark of the one presiding individual architect or artist is found in each. Compared to the architect of York Minster, the one who built Salisbury was altogether inferior. This feature of local varieties in style, the result of the influence of individuals, is from this period one of the most noteworthy features in English art; and generally one man influenced the work in his own diocese or district, and no further. Throughout the period before us—1189 to 1272—the developments were all in the same direction as during the previous time of transition. The tendency was always to greater lightness and elegance; skilful combinations were much thought of; and, towards the end of the period, there was even too great a display sometimes of the cleverness of the artist. But with work so really beautiful as it all was, and so uniformly good in the smallest nearly as much as in the largest building, it is ungracious, if not conceited, to affect to criticise the spirit in which the artist worked. The use of delicate shafts of polished marble (obtained in great part from the Isle of Purbeck) for doorways, windows, and arcades, is one of the distinguishing features of the style at this time. Generally they are treated with great beauty, but there were structural inconveniences about them which soon began to be felt. The columns were of necessity set out of their natural bed, and so began very soon to decay. It was necessary also to combine them together in groups, and to trust to the capitals, bands, and bases holding them together, and such construction not only looks dangerously slight, but is so. A radical defect also in engaged marble shafts is that, though they seem to be intended to do all the work and carry all the weight, they do in point of fact, wherever it can be contrived, carry no weight at all, and it was, no doubt, when and as this was discovered, that the mediæval builders gradually lost their liking for them, and returned to safer, if less brilliant, construction in stone, with piers formed with mouldings instead of shafts detached from the wall.

The characteristic elegance of the general architectural design was carried out in all the details. The mouldings were delicately rounded and alternated with hollows so drawn as to give here delicate and there most forcible effects of light and shade. Thus the dark line produced by marble in a pier was continued by means of a dark shadow in the arch; and without considerable knowledge of the science of moulding, it is impossible to do justice to this part of the English Early Pointed work, which has never been surpassed, if, indeed, it has ever been equalled at any period elsewhere. The groined roofs were still simple in design, but a ridge rib was often added to the necessary transverse and diagonal ribs of the previous period. This gave a certain hardness of line to the vault; it was the first step to the more elaborate and later systems of vaulting, and was soon followed by the introduction of other ribs on the surface of the vaulting cells. Few works are more admirable than some of the towers and spires of this period, but space will not allow of mention even of many of its best features. Probably the greatest excellence ever attained in English art was reached in this period by the architects of the great Yorkshire abbeys. No buildings in Europe surpass them in purity of general design, excellence of construction, beauty of detail, or suitability for their purposes. And it is a misfortune of the gravest kind for future generations, that their ruined condition forbids the possibility of our descendants appreciating as we can these consummate works of the most golden period of English art.

Later styles. The transition from the simplest Early Pointed to a more advanced style can be seen as well in Westminster Abbey as anywhere. Here traceries began to take the place of simple lancet openings, and led to that system of window tracery which was, in fact, the distinguishing feature of the succeeding style. When the invention of tracery was complete, everything in Gothic architecture rapidly changed. The art of masonry and stone-cutting was rapidly developed. Moulded stones, from being made continuous round the intricate combinations of window traceries, came naturally to be used much more largely than before in place of simple bearing shafts. So columns came to be formed of clusters of mouldings; and, in the case of groined buildings, each moulding of the shaft was developed into more mouldings above the capital, or even frequently carried on to the vault without any capital at all. Traceries were first of all commenced by merely piercing geometrical patterns or circles through the thickness of the walls. Then these patterns were combined under one enclosing arch; and then, when this sort of tracery had reached perfection, it was found possible to vary it indefinitely by making use of double curves (or ogee lines); and then, when these had been used for a short time, flowing lines, wandering gracefully over the space to be filled, and sometimes drawn by hand, supplanted the more formal outlines of the earlier work. The difference was great between an opening which was made (as the earlier examples were) with a sole view to the opening for glass, and one which was the accidental result only of the pretty lines and curves made by regarding the monial of the window, and not the light, as the thing to be considered. The tendency of the modification was to make men think lines of more importance than masses; and, whether consciously or not, this was just what happened: not only window traceries but mouldings, carvings, and every other feature, were entirely changed in character. The soft gradations of the early mouldings were given up for combinations of more hardly defined and thinner lines of light and shade, and, in harmony with this change, a crisp and sharp imitation of natural foliage was devised, which supplanted the rich and round forms of the earlier sculpture. The whole practice of art was becoming more scholarly, perhaps, but at the same time it was more conscious, and the cleverness of the architect was almost as often suggested as the noble character of his work. Merton College chapel, Oxford, the nave of York Minster, the choir of Selby, the whole of Exeter Cathedral, are a few among the many examples of this period of which this country can boast, and it will be seen that the change in character which is evident between the earliest and latest Middle Pointed works is enough to justify those who would again subdivide the nomenclature. The difficulty is that, where progress was so constant, it will be necessary, in order to be exact, to subdivide each century five or more times in order to be really definite.

Towards the end of Edward the Third's reign, the last great change was made. The first example of this is seen in the western end of the nave of Winchester, followed soon after by William of Wykeham's magnificent (if somewhat cold) reconstruction of the rest of the nave. It may fairly be held that the moving cause for the change was a sense of disgust at the vagaries into which the votaries of curvilinear window traceries had been led. There was something weak and effeminate about their work, and Edyngton and Wykeham, when they built the nave of Winchester, were evidently endeavouring to return to a simpler and more dignified style of building. The first thing they found to amend was the exuberant tracery which was ruining architecture. They did not return to earlier forms, but they corrected this exuberance by introducing vigorous, straight, vertical, and horizontal lines. These, combined with subarcuation, gave their work at first a vigour which had latterly been wanting; and no one can look at Wykeham's great work without feeling that he succeeded in his effort to impress a sense of vigour and manliness on the whole of it. Unfortunately, the love of display and of the exhibition of skill which was so strong before was in no degree lessened, and the change in style did nothing permanently to check it. The fondness for straight in place of flowing lines was more and more developed. Doorways and arches were enclosed within well-defined square outlines, walls were divided by panelling into rectangular divisions; vertical lines were emphasised by the addition of pinnacles, and buttresses used more for ornament than strength, whilst horizontal lines were multiplied in string-courses, parapets, and transomes to windows. Groined roofs, which in the 14th century had been enriched by the multiplication of surface ribs, were now most elaborately enriched by cross ribs subdividing the simple spaces naturally produced by the intersection of necessary ribs into small panels; these, again, were filled in with tracery, and finally, the key-stones were formed into pendants, and the branching ribs so radiated as to produce the really beautiful and very English variety of groining called fan-tracery. The amount of skill shown in the construction of these vaults was very great, and most of them have proved their authors' science by the perfect way in which they have endured to the present time. In other respects the architects of the 15th century were very successful. Few things can be seen more beautiful than the steeples of Gloucester Cathedral, or of St Mary's, Taunton. The open timber roofs, as for instance that of St Peter, Mancroft, Norwich, are superb. And, finally, they left us a large number of enormous parish churches all over the country, full of interesting furniture and decoration, and also a store of interesting examples of domestic architecture which are still the ornaments, and are associated with all the most interesting historical localities, of the country.

After the middle of the 16th century the practice of Gothic architecture practically died out, though traces of its influence, especially in rural districts, were hardly lost until the end of the 17th century. Good, sound, solid, and simple forms, well constructed by men who respected themselves and their work, and did not build only for the passing hour, were still popular and general, so that the vernacular architecture to a late period was often good and never absolutely uninteresting. But it presents none of the characteristics of a school, and cannot be treated of here.

The history of the development of Gothic architecture in England has been gone into at rather greater length than will be desirable in the case of other national developments. And this for two reasons: the examples which illustrate it are more generally known; and as the developments in other countries north of the Alps went through very nearly the same course of change at the same time, much has been said which need not be repeated in treating of them.

A few words will suffice for the necessary notice of the progress of Gothic architecture in Scotland and Ireland. In point of fact, most of what was done in the best period—that is, during the 13th and 14th centuries—was done by English artists, and is in no way more distinct in character than their work was in different dioceses or counties. The Gothic of Lincolnshire, of the eastern counties, of Kent and Sussex, of Somersetshire and South Wales, of Devon and Cornwall, and of Yorkshire, were distinct varieties of style full of local peculiarities. In the case of Scotland, the Scotland. best buildings which remain did not grow up in the same way by the efforts of local architects, but appear to have been the work of architects brought for the purpose from England, north of the Humber. There is a broad distinction between English art north and south of the Humber; and though it is easy to point to evidences of similarity between Scotch buildings and those north of the Humber, it is not possible to show the same connection with any buildings to the south of it. The evidences of general similarity are to be seen everywhere; it will suffice to mention one or two examples of particular similarity. The beautiful 13th century transept of Hexham Abbey church has some of its most marked features repeated in the also very beautiful transept of Pluscardine Abbey near Elgin. The architect of Lanercost in Cumberland was certainly responsible also for Dryburgh Abbey, either as actual architect, or as having inspired the architect. The buildings generally have, on both sides of the border, the same details, the same general disposition of plan, the same traceries; and there is nothing to indicate that those to the north of the border are not English. In truth, until the end of the 14th century the two styles are identical. Then Scotch art became more national, because it separated itself from

English, and, borrowing some of its inspiration from abroad, developed in a certainly picturesque and interesting line. Melrose Abbey is one of the most national, as it certainly is one of the most charming, of Scotch buildings; but its influence does not seem to have been extensive, and it must be classed as a variety of the latest English Middle Pointed, executed by Scotchmen who knew something of English work, and as much of French (if not of Iberian) art, but who were determined to leave the mark of their own hands and minds on their buildings. The other most remarkable late ecclesiastical building is the famous chapel at Rosslyn; but the art of this is in no sense whatever Scotch, and we must look again, probably, to Portugal as the country of whose art it is an example. Scotland has been unfortunate, in that ecclesiastical changes have involved the disuse and ruin of so many of her ecclesiastical buildings. But still enough remains to make the country a most interesting field of study in regard especially to the art of the 13th century. Glasgow, St Andrews, Kirkwall, Dunblane, and Elgin Cathedrals, and the Abbeys of Pluscardine, Sweetheart, Kelso, Dryburgh, Jedburgh, Holyrood, Dundrennan, and Melrose, afford a series as beautiful as any that can be named elsewhere, though most of them are on a moderate scale in their dimensions.

The domestic remains in Scotland are far more numerous, and full of picturesque beauty and magnificence. They are a distinctly national class of buildings of great solidity, and a great deal was sacrificed by their builders to the genius of the picturesque. They can only be classed with the latest Gothic buildings of other countries, but the mode of design shown in them lasted much later than the late Gothic style did in England. The vast height to which their walls were carried, the picturesque use made of circular towers, the freedom with which buildings were planned at various angles of contact to each other, and the general simplicity of the ordinary face of the walling, are all distinct features in them, and make them more worthy of admiration than most works of the corresponding period in England.

Ireland. In Ireland the progress of Gothic was very similar to that which we have seen in Scotland; but here may be seen art carried in the train of an invading army to the advantage of the country conquered, just as in England a similar benefit had been conferred by the Normans. Strongbow's invasion may be said to have been the introduction to Ireland of Gothic art. He went from South Wales to the south of Ireland. The art in his time in South Wales was to a great extent the development of the monks of Glastonbury. Their influence is visible plainly not only over their own district, but equally at Llandaff and at St David's. It was a very English influence. The Norman art of Canterbury hardly reached or touched them in a very direct way; and their art was taken directly and unmodified to Ireland. Among the buildings erected by the English in Ireland, Kilkenny Cathedral and the two 13th century cathedrals of Dublin—Christ Church and St Patrick's—are the most remarkable, but there are many others. Their style is most plainly that of the Englishmen who followed Strongbow, with no concession to, or consideration of, previous Irish forms of art. That these forms deserved respect cannot be doubted by those who have examined the existing remains. Cormac's chapel, which still stands uninjured by the side of the ruined English cathedral on the rock of Cashel, is one of the most interesting relics left. It is a much decorated Romanesque chapel; of two stages in height, groined in stone, and covered with an ingeniously and admirably constructed, lofty stone roof. For ever is a long time, but few buildings have ever been built which seem more likely to defy eternally the ordinary wear and tear of time than this. It is still perfect; and where beautiful design and perfect construction are combined as they are here, the highest excellence of which architecture is capable has been achieved. The round towers of Ireland are well-known and remarkable erections, but they can hardly be said to have any architectural character. In a mastery of the finer kind of decorative work few workmen have ever equalled the Irish; none have surpassed them. Their ornaments in metal-work and in illuminated MSS. are truly exquisite and marvellous in their ingenuity. But in masonry, the only works in which the same mastery is shown are the beautiful memorial or churchyard crosses which are so well known and so characteristic.

Gothic Architecture in France.

The remarks which have already been made as to the variation in style visible in various parts of the same country, apply with more force, perhaps, in what we now call France than to any other part of Europe. For the purposes of complete study it would be necessary to keep entirely distinct from each other in the mind the following important divisions:—(1.) Provence and Auvergne; (2.) Aquitaine; (3.) Burgundy; (4.) Anjou and Poitou; (5.) Brittany; (6.) Normandy; (7.) the Ile de France and Picardy; (8.) Champagne; and, finally, (9.) the eastern border-land (neither quite German nor quite French in its character), the meeting-point of the two very different developments of French and German art. Speaking generally, it is safe to say that Gothic architecture was never brought to its highest perfection in any portion of the south of France. Aquitaine, Auvergne, and Provence were too wedded to classic traditions to excel in an art which seems to have required for its perfection no sort of looking back to such a past. Hence there is no Gothic work in the south for which it is possible to feel the same admiration and enthusiasm as must be felt by every artist in presence of the great works of the north. In Anjou this is less the case; but even there the art is extremely inferior to that which is seen in Normandy and the Ile de France. Brittany may be dismissed from consideration, as being, like our own Cornwall, so provincial and so cut off from neighbours, that its art could not fail to be very local, and without much influence outside its own borders. The interest felt by the student of the history of the art need not, however, be less in the south than in the north. The Romanesque churches of Aquitaine and the south had immense influence. The church of St Front at Périgueux was built by a Venetian colony, in imitation (as far as its plan and section) of St Mark's at Venice. Its plan, a simple Greek cross, covered with four cupolas, is as essentially Venetian and Byzantine as it was possible to be; and the Venetian church was essentially Byzantine as opposed to Romanesque. This Byzantine or Venetian example spread far and wide over the great province of Aquitaine, and beyond its limits. A long series of churches might be named in all of which the domical character of the roofing is remarkable; and it need hardly be said that such a system of roofing cannot be adopted without a great influence on the form of the ground-plan. Sometimes these domes were treated, as at Loches, like great cones; and nearly always one of the objects of their constructors was to finish them with masonry, inside and out, in what might be held to be an indestructible manner. At the same time that these churches were rising, we see that in the valley of the Rhone churches were being built, strictly Romanesque in style, founded on the Roman traditions developed from the basilica, and without any evidence whatever of Byzantine influence. Ere long each of these two schools reacted on the other, and the result is seen in the extraordinarily interesting churches of the Puy de Dome and of Auvergne, where the Romanesque plan is adopted, with the addition of domical vaults at the crossings, and domically roofed chapels round the domical apses. But in these examples the plan is not that of the Greek, but distinctly that of the Latin cross. The architects of Aquitaine, again, influenced those of Poitou and Anjou. The church at Fontevrault, for instance, has a nave covered with a series of domes, but is of the long form of the Latin cross; and the churches of the Gothic period along the banks of the Loire, as at Saumur and elsewhere, have domical vaults entirely unlike the Gothic vaults which were being constructed at the same time to the north of them. So, too, the cathedral at Angers, where the domes are carried on pointed arches, and date from the 13th century. And it is not a little strange, considering the connection which existed between this part of France and England for so considerable a period, that absolutely no architectural influence should be traceable of one upon the other. In plan, in detail, and, above all, in systems of vaulting, the English and the Angevine schools are as distinct and as unlike each other as they well could be. The mode of roofing adopted by the Romanesque architects of France was generally quite different from the Byzantine plans just referred to. Their favourite mode was to cover the nave with a waggon vault, and to support this by a quadrant vault over the aisles, which gave, in fact, a continuous flying buttress along the whole length of the vault. These vaults were covered with flat stone roofs; there was no timber in their construction, and they have generally been preserved perfect to the present day. In all these churches the distinguishing feature is the plan of the eastern arm of the cross, a circular-ended apse with an aisle round it, and small apsidal chapels at intervals projecting beyond the aisle. What the exact origin of this beautiful termination was it is difficult to say certainly. But it is obvious that such a plan at that of the temple of Minerva Medica at Rome—a decagon surrounded by apsidal recesses—led naturally to that of the Christian church of San Vitale, Ravenna, and this to the almost similarly planned termination of the great abbey church at Cluny in Burgundy. But in whatever way these early *chevets* (as the French term them) grew up, there is no doubt that they contained the germ of the magnificent *chevets* of the complete Gothic churches of the north of France. A point to be noticed, in comparing these buildings with those in England, is the much greater frequency of stone vaults all over France from the first. The wooden roof to the nave, so common in England, was very rare in France; and the variety of early stone roofs was much greater there than here. As has been seen, the earliest forms were the waggon vault and the dome; the former constructed on aisled churches, the latter upon aisleless buildings. One of the earliest examples of a quadripartite vault (*i.e.*, one formed by the intersection of two barrel vaults at right angles to each other), is that over the nave of the grand abbey of Vézelay in Burgundy. This was erected in the middle of the 12th century; it was a hazardous experiment, and though it still stands, the wonder of all who see it for its magnificent size and architectural character, its construction was not satisfactory, and the thrust of its vaults had to be met by the erection of rude flying buttresses soon after its foundation. But the covering of so vast a building with such a vault was an achievement sure to be imitated, and it is easy to see how the influence of such an example could be felt all over the country at the time that the pointed arch was coming into use, with all its convenient aids for the construction of such vast vaults. At Vézelay there is no triforium; the space against which the roof of the aisles abuts is a plain wall, and the example of many Romanesque churches, in which the double aisles of Roman buildings (*e.g.*, St Agnese) were imitated, soon suggested the introduction of the triforium gallery between the arcades and the clerestory; whilst the necessity for light in northern climates developed of necessity the lofty clerestory. Here, therefore, the French architects found themselves in possession of all the elements of design, out of which they developed their magnificent Gothic works. There were difficulties, however, with their ground-plans, which were hardly ever quite surmounted; but as English architects were wedded to the square east end, Frenchmen were devoted to the apsidal. And it was in the planning of the apse, with its surrounding aisles and chapels, that all their ingenuity and science were displayed. A simple apse is easy enough of construction, but directly it is surrounded by an aisle or aisles, with chapels again beyond them, the difficulties are great. The bays of the circular aisle, instead of being square, are very much wider on one side than the other, and it is most difficult to fit the vaulting to the unequal space. In order to get over this various plans were tried. At Notre Dame, Paris, the vaulting bays were all triangular on plan, so that the points of support might be twice as many on the outside line of the circle as on the inside. But this was rather an unsightly contrivance, and was not often repeated, though at Bourges there is something of the same sort. At Le Mans the aisle vaulting bays are alternately triangular and square; and this is, perhaps, the best arrangement of all, as the latter are true and square, and none of the lines of the vault are twisted or distorted in the slightest degree. The arrangement of the chapels round the apse was equally varied. Usually they are too crowded in effect; and, perhaps, the most beautiful plan is that of Rouen Cathedral, where there are only three chapels with unoccupied bays between, affording much greater relief and variety of lighting than the commoner plan which provided a chapel to every bay.

Space will not admit of carrying this point farther, but it has been necessary to say thus much, because the planning and design of the *chevet* is the great glory of the French mediæval school. When the same thing was attempted, as by us at Westminster, or by the Germans at Cologne, it was evidently a copy, and usually an inferior copy, of French work. No English works led up to Westminster Abbey, and no German works to the cathedral at Cologne. When once the Gothic style was well established, the zeal with which the work of building was pursued in France was almost incredibly great. A series of churches exists there within short distances of each other, so superb in all their features, that it is impossible to contest their superiority to any corresponding group of buildings. The old Domaine Royale is that in which French art is seen in its perfection. Notre Dame, Paris, is a monument second to nothing in the world; but for completeness in all its parts it would be better to cite the cathedral of Chartres, a short description of which must suffice as an explanation of what French art at its zenith was. The plan has a nave with aisles, transepts with aisles on each side, a choir with two aisles all round it, and chapels beyond them. There are two immense steeples at the west end, two towers to each transept, and two towers at the junction of the choir with its apse. The doorways are triple at the west end, whilst to each transept is a vast triple porch in front of the three doorways. The whole of these doorways are covered with sculpture, much of it refined, spirited, and interesting in the highest degree. You enter and find the interior surpassing even the exterior. The order of the columns and arches, and of all the details, is so noble and simple that no fault can be found with it. The whole is admirably executed; and, finally, every window throughout its vast interior is full of the richest glass coeval with the fabric. This is a French cathedral at its best, but Amiens and Bourges, and Rheims and Laon, and Caen, Troyes, Le Mans, and a host of other churches, might be named only inferior to this. As compared with English churches of the same class, there are striking differences. The French architects aimed at greater height, greater size, but much less effect of length. Their roofs were so lofty that it was almost impossible for them to build steeples which should have the sort of effect that ours have. The turret on Amiens Cathedral is nearly as lofty as Salisbury spire, but is only a turret; and so throughout. Few French churches afford the exquisite complete views of the exterior which English churches do; but, on the other hand, their interiors are more majestic, and man feels himself smaller and more insignificant in them than in ours. The palm must certainly be given to them above all others.

Later French architecture ran a very similar course to that which has been already described in England. The 13th century was that in which it was seen at its best. In the 14th the same sort of change took place as elsewhere; the art was beautiful, but it was too much an evidence of skilfulness and adroitness. It was harder and colder also than English work of the same age; and when it fell, it did so before the inroads of a taste for what has been called Flamboyant architecture,—a gay and meretricious style which trusted to ornament for all its effect, and, in spite of many beauties. had none of the sturdy magnificence of much of our English Perpendicular style.

There is no country richer in examples of architecture than France.. It has been seen how infinitely varied they are in the different provinces; but the student who wishes to understand what it was possible for a country to do in the way of creating monuments of its grandeur, would find in almost every part of the country, at every turn and in great profusion, works of the rarest interest and beauty. The 19th century may be the consummation of all, but the evidences of its existence to posterity will not be one-tenth in number of those which such a reign as that of Philip Augustus has left us, whilst none of them will come up to the high standard which in his time was invariably reached.

Gothic Architecture in Germany.

It is impossible to say so much in praise of the German examples of Pointed architecture as has been said of both French and English. The history of the development of the art is very different, but in many respects very curious. We have first certain absolutely Roman works, such as those at Trèves; then others, of which the convent at Lorsch is a conspicuous example, which are in the truest sense Romanesque, *i.e.*, works directly founded on the Roman buildings of the country. Then comes a great group of churches, of which those in Cologne and the Rhineland are the best known examples, which are evidently founded on the Lombard churches of the north of Italy. The earlier of these churches date from the beginning of the 12th century, and the same style is continued on with but little serious alteration down to the end of the 13th century, when the strange spectacle is seen of a style which is completely Romanesque in its general character being suddenly supplanted by a style which in no way grew out of it, but which was rather an imitation of a foreign style, and which is distinguished by the perfect and complete form which it at once assumed. This style, the complete Gothic of Germany, in its turn retained its sway much longer than the corresponding styles elsewhere, and was finally supplanted by a very national German style, answering in point of date to our own late Third Pointed and to French Flamboyant. The question naturally arises, whether these styles, which are so wanting in evidence of natural growth, are to be looked at as sudden German inventions, or whether they are not illustrations of the conservative character of a people not fond of change, resisting it as long as possible, and at last, when obliged to take it at all, compelled to accept it in the most decided form. In illustration of what has been said, the following dates will be useful:—St Gereon, Cologne, was begun in 1200, and vaulted in 1227; St Cunibert, also in Cologne, was building from 1205 to 1248; Naumburg Cathedral has a nave of 1200; Limburg is but little later; Gelnhausen was begun in 1250, and Munster-Maifeld about the same time. All these churches are of such a character, that if we were to see them in France we should, no doubt, put them down as works of the end of the 12th century, and should look for another class to fill up the gap between that time and the commencement of the cathedral at Cologne in 1270. In short, transitional works are as rare in Germany as they are common in England and France. There is comparatively little evidence of natural growth, and a very practical refutation, therefore, of the claim which has been advanced by some German writers on behalf of their country, for the honour of being the real mother and inventor of northern Gothic.

The ground-plans of German Gothic churches have a character of their own. The apsidal termination of the east end is usual, though not quite universal; but it is to be noted that German apses are very rarely surrounded by aisles and chapels. Cologne Cathedral, which is the grandest exception to the rule, was notoriously inspired by, and in a way copied from, Amiens, and St Godehard at Hildesheim, Magdeburg Cathedral, and the Marien-Kirche, Lübeck, are inferior to French examples of the same ages. The German churches were either simply apsidal, or parallel triapsidal, or transverse triapsidal; and the main difference between early and late examples is that the former were circular, the latter polygonal in outline. Another feature peculiar to Germany is that of double choirs, *i.e.*, churches with apses both at the east and west ends. Examples of this are seen in Laach, Bamberg, Naumburg; in St Sebaldus, Nuremberg; and in Augsburg Cathedral. Even when the ground-plan shows a disposition of aisles and chapels like the French *chevet*, the design is treated very differently, the whole being generally covered in by one vast roof, instead of a series of roofs, and the aisles being of the same height as the choir. This class of building is very striking internally, owing to the vast height of the piers and arches; there is no triforium or clerestory, and the windows are extravagantly lengthened out. Still the examples of this kind of design—St Stephen, Vienna; Münster; the Wiesen-Kirche, Soest; St Laurence, Nuremberg; and Munich Cathedral, among a host of others—are very grand. The details of the earlier churches are evidently borrowed from the north of Italy. The walls are arcaded, and almost always finished under the eaves with open galleries, which were the beautiful substitutes of the Lombard architects for the classic cornice. The steeples of the same period are very peculiar. They are either square or octangular in plan, arcaded or pierced with windows regularly all over their face, and roofed with gables, or with spires rising out of the gables. The early groining was very simple, but always more or less domical in section. The windows were plain and rude, and the mouldings very simple and unskilful. In the interior the most marked feature of these churches is the great height of the triforium, which is still generally in use as a gallery, and is groined in the same way as the aisle. On the exterior the peculiarity of the plan and the large number of generally rather small, though lofty, steeples of picturesque outline are the most striking peculiarities.

The German Complete Gothic is essentially national in its complete character. It has a similarity to English and French Middle Pointed, but no more than this. It has many and obvious defects. From the first there is conspicuous in it that love of lines, and that desire to play with geometrical figures, which in time degenerated into work more full of conceit and triviality than that of any school of mediæval artists. These conceits are worked out most elaborately in the traceries of windows and panelling. The finest early examples are in the cathedral at Minden; a little later, perhaps, the best series is in the cloister of Constance Cathedral; and of the latest description the examples are innumerable. But it is worth observing that they rarely at any time have any ogee lines. They are severely geometrical and regular in their form, and quite unlike our own late Middle Pointed, or the French Flamboyant. In sculpture the Germans did not shine. They, like the English, did not introduce it with profusion, though they were very prone to the representations of effigies of the deceased as monuments.

In one or two respects, however, Germany is still possessed of a wealth of mediæval examples, such as is hardly to be paralleled in Europe. The vast collection of brick buildings, for instance, is unequalled. If a line be drawn due east and west, and passing through Berlin, the whole of the plain lying to the north, and extending from Russia to Holland, is destitute of stone, and the mediæval architects, who always availed themselves of the material which was most natural in the district, built all over this vast extent of country almost entirely in brick. The examples of their works in this humble material are not at all confined to ecclesiastical works; houses, castles, town-halls, town walls, and gateways, are so plentiful and so invariably picturesque and striking in their character, that it is impossible to pass a harsh verdict on the architects who left behind them such extraordinary examples of their skill and fertility of resource. Then, again, in regard to the furniture which before the period of the Renaissance of art and the Reformation of religion filled the ancient buildings, the Germans have more than any other people been happily conservative. There are still churches in Germany in which it may be said that nothing has been changed since Luther's day except the use of the buildings. St Katharine's at Lubeck is turned into a museum, but is full of its old furniture. The choir of Halberstadt is unused, but everything, even to the hangings on the walls, remains as of old. In Nuremberg all the altars are preserved, and decked with altar-cloths and candles, though they are never used; and when so much toleration as to these externals has been shown, and so little desire for change exists, it may well be imagined that the opportunities for the study of the works of German Gothic architects in their completeness are unusually plentiful. During the last few years a vast number of books have been published on the subject of their national antiquities by German writers, and the amount of detailed information on the subject, which may be obtained by those who care for the study, is unbounded.

Gothic Architecture in Spain.

That which strikes the architectural student most forcibly in Spain is the concurrent existence of two schools of art during the best part of the Gothic period The Moors invaded Spain in 711 A.D., and were not finally expelled from Granada until 1492 A.D. During the whole of this period they were engaged, with more or less success, in contests for superiority with the Christian natives. In those portions of the country which they held longest, and with the firmest hand, they enforced their own customs and taste in art almost to the exclusion of all Gothic work. Where their rule was not permanent their artistic influence was still felt, and even beyond what were ever the boundaries of their dominion, there are still to be seen in Gothic buildings some traces of acquaintance with Arabic art not seen elsewhere in Europe, with the exception, perhaps, of the southern part of the Italian peninsula, and there differing much in its development. The mosque of Cordova in the 9th century, the Alcazar and Giralda at Seville in the 13th, the Court of Lions in the Alhambra in the 14th, several houses in Toledo in the 15th century, are examples of what the Moors were building during the period of the Middle Ages in which the best Gothic buildings were being erected Some portions of Spain were never conquered by the Moors These were the greater part of Aragon, Navarre, the Asturias, Biscay, and the northern portion of Galicia. Toledo was retaken by the Christians in 1085 A.D.; Tarragona in 1089, Saragossa in 1118, Lérida in 1149 Valencia in 1239, and Seville in 1248. In the districts occupied by the Moors Gothic architecture had no natural growth, whilst even in those which were not held by them the arts of war were of necessity so much more thought of than those of peace, that the services of foreign architects were made use of to an extent unequalled in any other part of Europe.

Of early Christian buildings, erected probably from the 8th to the 11th centuries, there is every reason to believe that some remains still exist. The most interesting of these is Sta Maria de Naranco, near Oviedo, a building whose details are founded on Roman, but whose plan has all that adaptation to special requirements which is so distinct a mark of mediæval work. The buildings which come next in point of date to these are all evidently derived from, or erected by the architects of those which were at the time being built in the south of France. These churches are uniform in plan, with central lanterns and three eastern apses. The nave has usually a waggon or barrel vault, supported by quadrant vaults in the aisles, and the steeples are frequently polygonal in plan. If these churches are compared with examples like that of the cathedral at Carcassonne on the other side of the Pyrenees, their identity in style will at once be seen. A still more remarkable evidence of similarity has been pointed out between the church of St Sernin, Toulouse, and the cathedral of Santiago. The plan, proportions, and general design of the two churches are identical. Here we see a noble ground-plan, consisting of nave with aisles, transepts, central lantern, and *chevet*, consisting of an apsidal choir, with a surrounding aisle and chapels opening into it at intervals. This example is the more remarkable, inasmuch as the early Spanish architects very rarely built a regular *chevet*, and almost always preferred the simpler plan of apsidal chapels on either side of the choir. And its magnificent scale and perfect preservation to the present day combine to make it one of the most interesting architectural relics in the country.

Among the more remarkable buildings of the 12th and the beginning of the 13th century are San Isidoro, Leon; San Vicente, Avila; several churches in Segovia; and the old cathedral at Lérida. They are much more uniform in character than are the churches of the same period in the various provinces of France, and the developments in style, where they are seen at all, seldom have much appearance of being natural local developments. This, indeed, is the most marked feature of Spanish architecture in all periods of its history. In such a country it might have been expected that many interesting local developments would have been seen; but of these there are but one or two that deserve notice. One of them is illustrated admirably in the church of St Millan, Segovia, where beyond the aisles of the nave are open cloisters or aisles arcaded on the outside, and opening by doors into the aisles of the nave. It would be difficult to devise a more charming arrangement for buildings in a hot country, whilst at the same time the architectural effect is in the highest degree beautiful. The universality of the central tower and lantern has been already mentioned. This was often polygonal, and its use led to the erection of some lanterns or domes of almost unique beauty and interest. The old cathedral at Sala-

front elevation.

manca, the church at Toro, and the cathedral of Zamora, all deserve most careful study on this score. Their lanterns are almost too lofty in proportion to be properly called domes, and yet their treatment inside and outside suggests a very beautiful form of raised dome. They are carried on pointed arches, and are circular in plan internally, and octagonal on the exterior, the angles of the octagon being filled with large turrets, which add much to the beauty of the design, and greatly also to its strength. Between the supporting arches and the vault there are, at Salamanca, two tiers of arcades continued all round the lantern, the lower one pierced with four, and the upper with twelve lights, and the vault or dome is decorated with ribs radiating from the centre. On the exterior the effect is rather that of a low steeple covered with a stone roof with spherical sides than of a dome, but the design is so novel and so suggestive, that it is well worth detailed description. Nothing can be more happy than the way in which the light is admitted, whilst it is also to be noted that the whole work is of stone, and that there is nothing in the design but what is essentially permanent and monumental in construction. The only other Spanish development is the introduction, to a very moderate extent, of features derived from the practice of the Moorish architects. This is, however, much less seen than might have been expected, and is usually confined to some small feature of detail, such, *e.g.*, as the carving of a boss, or the filling in of small tracery in circular windows, where it would in no way clash with the generally Christian character of the art.

The debateable period of transition which is usually so interesting is very sterile in Spain. A good model once adopted from the French was adhered to with but little modification, and it was not till the 13th century style was well established in France and England that any introduction of its features is seen here; and then, again, it is the work of foreign architects imported for the work and occasion, bringing with them a fully developed style to which nothing whatever in Spain itself led up by a natural or evident development. The three great Spanish churches of this period are the cathedrals of Toledo, Leon, and Burgos. Those of Siguënza, Lérida, and Tarragona, fine as they are, illustrate the art of the 12th rather than of the 13th century, but these three great churches are perfect Early Pointed works, and most complete in all their parts. The cathedral of Toledo is one of the most nobly designed churches in Europe. In dimensions it is surpassed only by the cathedrals of Milan and Seville, whilst in beauty of plan it leaves both those great churches far behind. The *chevet*, in which two broad aisles are carried round the apse with chapels alternately square and apsidal opening out of them, is perhaps the most perfect of all the schemes we know. It is as if the French *chevets*, all of which were more or less tentative in their plan, had culminated in this grand work to which they had led the way. The architectural detail of this great church is generally on a par with the beauty and grandeur of its plan, but is perhaps surpassed by the somewhat later church at Leon. Here we have a church built by architects, whose sole idea was the erection of a building with as few and small points of support as possible, and with the largest possible amount of window opening. It was the work of men whose art had been formed in a country where as much sun and light as possible were necessary, and is quite unsuited for such a country as Spain. Nevertheless it is a building of rare beauty and delicacy of design. Burgos, better known than either of the others, is inferior in scale and interest, and its character has been much altered by added works more or less Rococo in character, so that it is only by analysis and investigation that the 13th century church is still seen under and behind the more modern excrescences.

The next period is again marked by work which seems to be that of foreigners. The fully developed Middle Pointed or Geometrical Gothic is indeed very uniform all over Europe. Here, however, its efforts were neither grand in scale nor interesting. Some of the church furniture, as, *e.g.*, the choir screens at Toledo, and some of the cloisters, are among the best features. The work is all correct, tame, and academical, and has none of the dignity, power, and interest which marked the earlier Spanish buildings. Towards the end of the 14th century the work of Spanish architects becomes infinitely more interesting. The country was free from trouble with the Moors; it was rich and prosperous, and certainly its buildings at this period were so numerous, so grand, and so original, that they cannot be too much praised. Moreover, they were carefully designed to suit the requirements of the climate, and also with a sole view to the accommodation conveniently of enormous congregations, all within sight of the preacher or the altar. This last development seems to have been very much the work of a great architect of Majorca, Jayme Fabre by name. The grandest works of his school are still to be seen in Catalonia. Their churches are so vast in their dimensions that the largest French and English buildings seem to be small by comparison, and being invariably covered with stone vaults, they cannot be compared to the great wooden-roofed churches of the preaching orders in Italy and elsewhere, in which the only approach is made to their magnificent dimensions. The cathedral of Gerona is the most remarkable example. Here the choir is planned like the French *chevet* with an aisle and chapels round it, and opens with three lofty arches into the east wall of a nave which measures no less than 73 feet in the clear, and is covered with a stone vaulted ceiling. In Barcelona there are several churches of very similar description; at Manresa another, but with aisles to its nave; and at Palma in Majorca one of the same plan as the last, but of even much larger dimensions. Perhaps there is no effort of any local school of architects more worthy of study and respect than this Catalonian work of the 14th and 15th centuries. Such a happy combination of noble design and proportions with entirely practical objects places its author among the very greatest architects of any time. It is one thing to develop patiently step by step from the work of one's fathers in art, quite another to strike out an entirely new form by a new combination of the old elements. In comparison with the works just mentioned the other great Spanish churches of the 15th century are uninteresting. But still their scale is grand, and though their detail is over-elaborated and not beautiful, it is impossible to deny the superb effect of the interior of such churches as those of Seville, Segovia, and Salamanca (new cathedral). They are very similar in their character, their columns are formed by the prolongation of the reedy mouldings of the arches, their window traceries are poorly designed, and their roofs are covered with a complex multitude of lierne ribs. Yet the scale is fine, the admission of light, generally high up and in sparing quantity, is artistic, and much of the furniture is either picturesque or interesting. The *tout ensemble* is generally very striking, even where the architectural purist is apt to grumble at the shortcomings of most of the detail.

The remarks which have been made so far have been confined to the fabrics of the churches of Spain. It would be easy to add largely to them by reference to the furniture which still so often adorns them, unaltered even if uncared for; to the monuments of the mighty dead, in which Spain is a worthy rival of our own country; to the sculpture which frequently adorns the doorways and screens; and to the cloisters, chapter houses, and other dependent buildings, which add so much charm in every way to them. Besides this, there are very numerous castles, often planned on the grandest scale, and some, if not very many, interesting remains of domestic houses and palaces; and most of these, being to some extent flavoured by the neighbourhood of Moorish architects, have more character of their own than has been accorded to the churches. Finally, there are considerable tracts of country in which brick was the only material used; and it is curious that this is almost always more or less Moorish in the character of its detail. The Moors were great brickmakers. Their elaborate reticulated enrichments were easily executed in it, and the example set by them was, of course, more likely to be followed by Spaniards than that of the nearest French brick building district in the region of Toulouse. The brick towers are often very picturesque; several are to be seen at Toledo, others at Saragossa, and, perhaps the most graceful of all, in the old city of Tarazona in Aragon, where the proportions are extremely lofty, the face of the walls everywhere adorned with sunk panels, arcading, or ornamental brickwork, and at the base there is a bold battered slope which gives a great air of strength and stability to the whole. On the whole, it must be concluded that the mediæval architecture of Spain is of less interest than that of most other countries, because its development was hardly ever a national one. The architects were imported at one time from France, at another from the Low Countries, and they brought with them all their own local fashions, and carried them into execution in the strictest manner; and it was not till the end of the 14th century, and even then only in Catalonia, that any buildings which could be called really Spanish in their character was erected.

Gothic Architecture in Italy.

The history of the development of Gothic architecture in Italy brings out, more clearly than anywhere else, of course, the gradual transition from simple Roman work to Romanesque and Byzantine, and thence, finally, to Gothic. But the first portion of the history is, perhaps, the most important, since, owing to various causes, the Gothic architecture of Italy never achieved the same brilliant effects which marked its career in other parts of Europe. Something there was in the climate, something in the constant knowledge of grand works of classic times, and finally, something in the Eastern influence which was so marked in Venice, and in the Greek as well as Moorish or Arab influence which equally affected the whole southern half of the peninsula.

There can be no doubt whatever that the first buildings used for Christian worship in Italy were in no way whatever more suited for its functions than they were for the Pagan rites which had preceded them. The form of architecture used was the Roman art of the day; and to a considerable extent Roman buildings, and particularly basilicas, were converted, from the time of Constantine, into Christian churches. The early Christian policy was not unfrequently one which softened off the transition from the old worship to the new. And when the bishop took his seat in the centre of the apse, with his clergy on either side, and the Christian altar was placed in front of the apse, very much in the position of that which had been used for the Pagan sacrifice, the whole change required to convert the basilica into the church had been made. The basilica was usually a long nave with one or more aisles on either side. These aisles were frequently double in height, a second row or order of columns being placed above the first. At one end was a tribune sometimes square, but usually apsidal in plan, round which a series of steps led to seats formed against the wall. The central seat was that of the principal officer, the others those of his assessors, and the altar stood in front of the tribune. The central nave was either open to the sky, or covered with a wooden roof or with a vaulted ceiling. The basilica at Pompeii, still so perfect as to be quite intelligible, has a single aisle on each side, and a square-ended tribune, and was probably not covered over the centre. This, however, like all the early buildings in Pompeii, is rather Greek than Roman in its character. If we compare such buildings as this and the basilica of Trajan at Rome with the earliest existing churches built on the basilican type, we shall see how very slight the difference was for some hundreds of years. There is still the long unbroken nave with an apsidal head. Over the aisles are sometimes, as in St Agnese and St Lorenzo in Rome, second aisles or galleries opening to the nave. And the principal alteration or adaptation is one entirely of church furniture and screens, ambons and altars under baldachins, which, as if with a scrupulous regard to the old basilican arrangement, are planned independently altogether of the structure, being emphatically nothing but furniture. If we examine San Clemente in its present condition, we shall find a choir having no constructional peculiarities, but formed entirely by low screens built on the floor of the church, with a passage-way between them and the columns, and with ambons or pulpits projecting from their sides. In front of the church was an enclosed court-yard or atrium, from which access was gained to the church. The arrangements of San Clemente are probably not so old as they were once supposed to be. One, if not two, older churches exist beneath it; but, nevertheless, there is every reason for believing that the arrangements now visible are those at latest of the 9th century. The ancient basilica of St Peter was on the same sort of plan, with the addition of a cross nave or transept between the nave and its aisles and the apse, an arrangement which is still to be seen in the famous church of St Paul, without the walls, and in the basilica at Aquileia. At St Paul's the altar stands on the west side of the transept, the bishop's seat is separated from it by the transept, and the whole arrangement is unmeaning and unsatisfactory, but it is probably not old. The number of early churches on the basilican plan is very great, and they are of all sizes. The charming church of Sta Maria in Cosmedin, Rome, is a quite small building, but graceful in its general proportions, and interesting to the architect, like most of the early Roman churches, for the beautiful inlaid work, the Opus Alexandrinum, of its screens, pavements, and pulpits. Out of Rome, also, there are many examples of the same type, but space does not permit the mention here of any but those of Ravenna. The two most remarkable of these are St Apollinare in Classe, two or three miles out of the city, a forlorn and deserted building, and St Apollinare Nuovo, within the walls, a church whose mosaic decorations, being nearly perfect, give an admirable impression of the sumptuous character which the early church knew how to give and loved to give to its temples. Here, however, none of those old ritual arrangements remain, which give so much interest to the basilicas of Rome, Torcello, Toscanella, and Aquileia. The decoration of St Apollinare Nuovo is mainly on the space of wall between the arches opening to the aisles and the clerestory. It is a mosaic picture of an almost endless procession of white-clad saints on a golden ground. Few things in the whole realm of Christian art are more beautiful or more touching. The other St Apollinare, in Classe, has lost almost all its old decorations, and is merely painted in bad taste and in modern times. The Roman love of circular recesses or circular plans was very great. In the baths of Caracalla, for instance, we have them at every turn. The Pantheon is a vast circular building, with recesses in its walls (now used as chapels) alternately square and apsidal in plan; and in the temple of Minerva Medica these apsidal projections round the building are even more distinctly marked. This last example paved the way for the similarly planned church of San Vitale at Ravenna, which even now, overlaid as it is with meretricious decoration, affords us most interesting evidence of the way in which the constructional arrangements of Pagan Rome were copied and utilised by the Christians. But, usually, there was little to admire in the way in which this was done. The architect built up his church with fragments of classic columns, unequal in size or height, married to the wrong capitals and bases, and altogether as rudely put together as was possible. And so little development was there that, in the nave of the basilica of Aquileia, we have this done absolutely in the same way so late as the 14th century, the only difference being that in it the classic columns carry pointed arches and a clerestory of Gothic windows.

From these simple imitations of Roman buildings let us go to the 12th century church of St Ambrogio at Milan, and we shall see how much had by that time been done in the way of modification. The whole building is, of course, round arched. It has a western atrium or courtyard, and it has a nave and aisles, with an eastern apse to its nave. At first sight no alteration seems to have been made, but on further examination it will be found that the columns are alternately piers and clusters (at St Agnese every third column was made into a pier), that the arch orders have a proper connection with the plans of the columns, and that the church is vaulted. Let us now go back for an instant to the introduction of Byzantine plan and details in the church of St Mark at Venice. Here we have brought back again to Italy the product of the developed skill of the succession of artists, who, after constructing the mighty vaults of the Roman buildings, had removed to Constantinople with the empire, and had there grafted their knowledge on the art and practice of the East. It was there that they began to build domes, erected not on circular, but on square bases, the angles being supported on what are technically called pendentives. So fond of this construction were they that their buildings became almost always combinations of domes, instead of the simple nave, ended with a semi-dome, of the Roman architects of the day. This Byzantine style was developed with a skill and delicacy to which the decaying art of Rome was at the time quite a stranger, and it is less wonderful that so beautiful a church as St Mark should have had some influence, than that it should have had so little. But it is to the example of this and other Eastern churches, no doubt, that we owe the raised central lantern or dome which became a feature of so many churches from this time forward. A parallel may well be drawn here between two well-known and typical examples. These are the churches of San Zenone, Verona, and of San Michele, Pavia. In the former we still see the great simple and uniform plan of the wooden roofed basilican church, adorned with much that is Byzantine in feeling and character, but still emphatically a Romanesque building. In San Michele, on the contrary, we see a building which, if it owed something to Rome (as it did), owed at least as much to the East. Its plan was the distinctly cruciform plan, with a central lantern, not the Roman makeshift of a long nave with an Eastern transept, whilst its whole space being covered with vaulted roofs, instead of the Roman wooden ceiling to the nave, marks it as belonging to a different class. Besides this, the whole building is subdivided and constructed in so scientific a way as to show that its architect was in the path of a development leading far away from simple Roman theories of construction and plan. Here one of the most observable features is the fine open gallery under the external eaves of the roof, a device repeated constantly in the Lombard buildings, and transferred from them, with much else, to the valley of the Rhine, where it is the great feature of most of the 11th and 12th century churches, and of some even of the 13th century.

It is impossible here to make any lengthened reference to the buildings of Italy south of Rome. It must suffice to say that Rome herself seems to have had no influence on them during this early period. Their designs and decorations are full of a character which speaks of contact at times with Greece, at other times with the southern coast of the Mediterranean. Their walls are arcaded, and then adorned with square and circular panels, the details of which afford ample evidences of their origin. The arcades are sometimes, as at Foggia, of horse-shoe shape, and the extremely elaborate carving of foliage with which they are adorned is quite Byzantine in character. A comparison of the west fronts of Foggia or Troja, with the arcading of the church at Ani, in Armenia, will show much more similarity than with any Roman work; whilst the front of Sta Maria, Ancona, is planned in just the same fashion as that of the cathedral at Zara in Dalmatia. The one great North Italian church in which there was an attempt to fuse these two fashions of design is the cathedral at Pisa, where all the walls are arcaded and panelled, the mouldings mainly copied from the ancient forms, and the whole trust of the architect put, very much as it was in the South Italian and Byzantine works, in covering the walls with decoration. But these churches did nothing by way of paving the way for Italian Gothic, and need not therefore be further referred to.

Italy is poorer than any other country in examples of the transition from round arched to pointed arched buildings. The use of the pointed arch was accepted at last as a necessity, and cannot be said ever to have been welcomed. The first buildings in which it is seen worked out fully in detail are those of Nicola Pisano, and but few examples exist of good Gothic work earlier than his time. The elaborately arcaded and sculptured west front of Ferrara Cathedral is a screen to an early building. The cathedral and other churches at Genoa are certainly exquisite works, but they appear to owe their internal design rather to the influence of (perhaps) Sicilian taste than North Italian, and the exquisite beauty of the west front owes a good deal, at any rate, to French influence, softened, refined, and decorated by the extreme taste of an Italian architect. The feature which most marks all Italian Gothic is the indifference to the true use of the pointed arch. Everywhere arches were constructed which could not have stood for a day had they not been held together by iron rods. There was none of that sense of the unities of art which made a northerner so jealous to maintain the proper relations of all parts of his structure. In Nicola Pisano's works the arch mould rarely fits the capital on which it rests. The proportions of buttresses to the apparent work to be done by them are bad and clumsy. The window traceries look like bad copies of some northern tracery, only once seen in a hurry by an indifferent workman. There is no life, or development, or progress in the work. If we look at the ground-plans of Italian Gothic churches, we shall find nothing whatever to delight us. The columns are widely spaced, so as to diminish the number of vaulting bays, and to make the proportions of the oblong aisle vaulting bay very ungainly. Clustered shafts are almost unknown, the columns being plain cylinders with poorly sculptured capitals. There are no triforium galleries, and the clerestory is generally very insignificant. In short, a comparison of the best Gothic works in Italy with the most moderate French or English work would show at once how vast its inferiority must be allowed to be. Still there were beauties which ought not to be forgotten or passed over. Such were the beautiful cloisters, whose arcades are carried on delicate coupled shafts. Of these the first examples are in Rome, but they are to be seen all over Italy. Such, again, were the porches and monuments, of which some of the best are in Verona, of almost unsurpassed elegance; such the campaniles, both those of Rome, divided by a number of string-courses into a number of stages, and those of the North, where there are hardly any horizontal divisions, and the whole effort is to give an unbroken vertical effect; or that unequalled campanile, the glory of Florence, of Giotto, of art, the tower of the cathedral at Florence, where one sees in ordered proportion, accurately adjusted, line upon line, and stage upon stage, perhaps the most carefully wrought out work in all Europe. The Italian architects were before all others devoted to the display of colour in their works. St Mark's had led the way in this, but, throughout the peninsula, the bountiful plenty of nature in the provision of materials was only seconded by the zeal of the artist, and on this point a few notes may be added at the conclusion of this summary. They were also distinguished for their use of brick. Just as in parts of Germany, France, Spain, and England, there were large districts in which no stone could be had without the greatest labour and trouble; and here the reality and readiness which always marked the mediæval workman led to his at once availing himself of the natural material, and making a feature of his brickwork. This is a subject which, however, cannot well be treated save at the same time as other developments of brick building in other districts similarly situated. In conclusion, it must be said that the Gothic of Italy has no such grand works to show as more northern countries have. The buildings were seldom thoroughly beautiful as complete works of architecture. Allowance has to be made at every turn for some incompleteness or awkwardness of plan, design, or construction. There is no attempt to emulate the beauties of the best French plans. Milan Cathedral, magnificent as its scale and material make it, is clumsy and awkward both in plan and section, though its vast size makes it impressive internally. San Francesco, Assisi, is only a moderately good early German Gothic church, converted into splendour by its painted decorations. At Orvieto a splendid west front is put, without any proper adjustment, against a church whose merit is mainly that it is large and in parts beautifully coloured. The later Pisan buildings are far finer, the altered baptistery especially being a magnificent work, though words can hardly describe the architectural defects of such work as that of the Campo Santo, where, again, it is the painter, not the architect, who has worked such wonders. The finest Gothic interiors are of the class of which the Frari at Venice and Sta Anastasia at Verona are examples. They are simple vaulted cruciform churches, with aisles and chapels on the east side of the transepts. But even in these the designs of the various parts in detail are poor and meagre, and only redeemed from failure by the picturesque monuments built against their walls, by the work of the painter, and by their furniture. In fine, Gothic art was never really understood in Italy, and, consequently, never reached to perfection.

If the architecture of Italy never fell away so much from the more classic style of imperial Rome as that of the northern nations did, neither did the Italian ever possess that more than equivalent, whose splendid course we have been describing. Whilst the Pointed style was almost exclusively known and practised in Northern Europe, the Italians were but slowly improving in their Gothic style; and the improvement was more evinced in their secular than in their ecclesiastical structures. Florence, Bologna, Vicenza, Udine, Genoa, and, above all, Venice, contain palaces and mansions of the 12th, 13th, 14th, and 15th centuries, which for simplicity, utility, and beauty far excel most of those in the same and other places of the three following centuries. The contemporary churches do not exhibit the same degree of improvement in style that is conspicuous in these domestic works, for there are no works in Europe more worthy of study and admiration than the Ducal Palace at Venice, and some of the older works of the same class, and even of earlier date. The town-halls of Perugia, Piacenza, and Siena, and many houses in these cities, and at Corneto, Amalfi, Asti, Orvieto, and Lucca, the fountains of Perugia and Viterbo, and the monuments at Bologna, Verona, and Arezzo, may be named as evidence of the interest which the national art affords to the architectural student even in Italy, as late as the end of the 14th century; but after this it gradually gave way to, though in some instances its influence may be traced even when it had been overborne by, the new style.

Modern Italian School of Architecture.

The opening of the Italian school of architecture on the resuscitated dogmas of Vitruvius was coincident with the gradual decay of the Pointed style. Fortunately, however, its effects were a full century in reaching England, and during that period many most elegant structures were erected, and many of those of earlier date which had been commenced before or during the wars of the Roses, and left unfinished, were completed. The first indication we have of the presence of the *Cinquecentist* in England, is in the tomb of Henry VII., which was executed by Torregiano, an Italian artist, who, it would appear, was obliged to have some respect to the style of the edifice in which his work was to rest; but his preconceived ideas of propriety and beauty were too strong to allow him to omit the characteristics of his school, and the result is a strange mixture of the two. From that time the Pointed style rapidly deteriorated, being overborne by the taste of the Renaissance. On the Continent the latter was already predominant, for, during the whole of the 15th century, the current had been setting from Italy over every part of Europe which received its religion from Rome, and this country was only the last to be overwhelmed by it.

The first step taken towards the revolution of architecture was by Filippo Brunelleschi, a Florentine architect, who was employed to finish the cathedral of his native city early in the 15th century; a work which had been commenced more than a century before on the design of Arnolfo, a Florentine also, but which still required the cupola when its completion was intrusted to Brunelleschi. The edifice is in the Italian Gothic style, which his affectation of superior taste and talent induced him to attempt to supersede, so as to bring the world back to the classic style of ancient Rome. The construction of the cupola gained him great reputation and the confidence of the public, which he employed to advance his favourite scheme. To use the words of an Italian writer on the subject, "On the example of so wise and skilled a man, other architects afterwards devoted themselves to free architecture from the monstrosities introduced by barbarism and excessive licence, and to restore it to its primitive simplicity and dignity." But to what did they have recourse to effect this? Did they examine and study the remains of antiquity in Greece and Rome, in Italy and elsewhere? No! they referred to the writings of an obscure Latin author, who professed to give the principles and practice of architecture among the Greeks and Romans, but paid no more attention to the existing architectural works of these nations than if they had never been, although one could hardly walk the streets of any of the old cities in the south of Italy without seeing Roman edifices, whilst Rome and its vicinity was, as it still is, full of them. All the use, however, that these self-called "restorers" of architecture made of the works of the

ancients, was to use them as lay-figures, or framework, to model on, according to the proportions and directions given by Vitruvius; and the effect was formality and mannerism in those who adhered to the dogmas of the school, and wild grotesqueness in those who allowed themselves to wander from them, whilst simplicity, and its consequence good taste, were effectually banished from the works of them all.

It may be necessary to remark here that the works of Vitruvius are of value mainly as records of the architectural practice and the opinions and acquirements of an architect of a distant age. His fables about the origin of building, the invention of the orders, and the arrangements which grew out of certain modes of construction, prove his total ignorance not only of the architectural works of the more ancient Eastern nations, but of those of Greece itself, which he professes to describe. His classical taste, in consequence of his knowledge of antiquity, is vaunted by Perrault, one of his commentators, and given by him as a reason why Vitruvius was not much employed by the whimsical Romans, who loved variety, to which he would not administer. But the extent to which his knowledge of antiquity, that is, of the works of the Greeks, extended, may be readily determined by comparing the designs of Greek structures, made by Perrault and others, according to the directions of Vitruvius, with the Greek structures themselves as they exist even at the present time. Not a single example of Greek architecture will bear out any of the rules which Vitruvius lays down, professedly on its authority; and not an existing edifice, or fragment of an edifice, is in form or proportion in perfect accordance with any law of that author, nor indeed are they generally in harmony with the principles he enunciates.

The Five Orders.

The adoption of the Vitruvian laws by the Italian architects of the 15th century led to the formation of the so-called "Five Orders." In speaking of the course of Greek and Roman architecture, mention has been made of the Doric, Ionic, and Corinthian styles. Vitruvius describes, in addition to these, another, which he calls Tuscan—possibly a style of columnar arrangement peculiar to Italy, and most likely of Etrurian origin; but, in the absence of delineations, the *Cinquecentists* could only apply the proportions he laid down for it to what appeared to approximate them in the ancient remains; and hence arose a fourth, or "the Tuscan Order." It is, however, a mere modification of the Roman debasement of the Doric, and may be considered, in its present form, as of purely modern Italian origin. The same "Revivers," on looking among the ruins of ancient Rome for the forms of their Vitruvian orders, found specimens of a foliated ordinance, which the bad taste of the Romans had compounded of the foliated and voluted styles of the Greeks. This was seized upon as a fifth style, subjected to certain rules and proportions, and called "the Composite Order." The very poor Roman specimens of Doric and Ionic fitted themselves without much difficulty to the Vitruvian laws; but the examples Rome afforded of the Corinthian were less tractable, and being as various in detail as they are generally beautiful, they were all passed over, and their places supplied by a mere changeling—an epitome of the Vitruvian theory. Thus we have the "Five Orders" of the Italo-Vitruvian school, viz.:—*first*, the Tuscan, of which there is no recognised example of antiquity, but which owes its form to the descriptions of Vitruvius and the fancies of the revivers; *second*, the Doric, a poor and tasteless arrangement of the general features of the style on a Roman model; *third*, the Ionic, which is almost as great a debasement of the Grecian originals, and was produced in the same manner as the last-mentioned; *fourth*, the Corinthian, a something totally unlike the ancient examples of both Greece and Rome in beauty and spirit; and, *fifth*, the Composite, an inelegant variety of the Corinthian, or a hybrid mixture of the horned or angular-Ionic volutes, with a deep necking of the foliage of the preceding order. The first to publish this system was Leon Battista Alberti, a pupil of Brunelleschi. He has been followed by many others, the most distinguished of whom are Palladio, Vignola, Scamozzi, Serlio, and De Lorme, architects, and Barbaro, a Venetian prelate, and an esteemed translator of, and commentator on, Vitruvius. None of these, it must be understood, agreed with any other of them, but each took his own view of the meaning of their common preceptor; and yet none of their productions evince the slightest approach to the elegance of form and beauty of proportion which distinguish the classic models of the columnar architecture of antiquity. Palladio and Serlio were the first to publish delineations and admeasurements of the Roman architectural remains in Italy; but the total absence of verisimilitude to the originals, and, in many cases, the absolute misrepresentations, in both works, prove how incompetent the authors were to appreciate their merits; and the exaggeration of their defects proves with equal clearness the general bad taste of the school in which they are masters. The worst qualities of the Roman school of architecture were embraced and perpetuated by the Cinquecento artists. The inharmonious and unpleasing combinations which arose out of the collocation of arches with columnar ordinances became the characteristics of the Italian; unequal intercolumniations, broken entablatures and stylobates, enter alike into the productions of the best and of the worst of the Cinquecento architects. The style of this school is marked, too, by the constant attachment of columns and their accessories to the fronts or elevations of buildings; by the infrequency of their use in insulated (their natural) positions to form porticoes and colonnades; by the thinness or want of breadth in the smaller members of their entablatures, and the bad proportions of the larger parts, into which they are divided; by the general want of that degree of enrichment which fluting imparts to columns; by the too great projection of pilasters, and the inconsistent practice of diminishing, and sometimes fluting them; by the use of circular and twisted pediments, and the habit of making breaks in them to suit the broken ordinance they may crown; and by various other inconsistencies and deformities, which will be rendered more evident when we come to treat of the style in detail. The merit of the Italian school consists in the adaptation and collocation of the prolate hemispheroidal cupola, which appears to have grown out of its opposite in the Roman works during the Gothic ages, as we find it in the early cathedrals; though it is highly probable that the idea was brought from the East, in the forms exhibited by the cupolas of St Mark's at Venice, and of Pisa Cathedral. A very imposing style of palatial architecture also was practised by many of the Italian architects. It consists of the use of a grand crowning cornice, running in one unbroken line, unsurmounted by an attic or anything of the kind, superimposing a broad, lofty, and generally well-proportioned front, made into graceful compartments, but not storied, by massive blocking courses or otherwise. Not unfrequently, however, the faults of the school interfere to injure a composition of this kind; for, to produce variety in the decorations of the windows, some of them have been made like doors, with distyle arrangements of columns, surmounted by alternations of circular and angular pediments, and sometimes with all the vagaries which deform the front of an Italian church. It is indeed the ecclesiastical architecture of the school in which its faults are most rife and its merits most rare. An Italian Renaissance church possesses nothing of the stern simplicity and imposing grandeur of an Egyptian sacred structure—nothing of the harmonious beauty and classic dignity of a Grecian fane—nothing of the ornate and attractive elegance of a Roman temple—and nothing truly of the glittering grace and captivating harmony of a Pointed cathedral. No other style of architecture presents so great a contrast, in any two species of its productions, as the Italian does, in one of its ordinary church fronts, with the front of a nobleman's mansion or palazzo, in the manner already referred to; and in no city of Italy is the contrast so strong, by the egregiousness of the examples it contains of both, as Rome. The stately portico is hardly known in Italian architecture; and in the rare cases in which insulated columns are found, they are for the most part so meagre in themselves, and so widely set, according to the Vitruvian laws, that the effect produced by them is poor and wretched in the extreme. This applies most particularly to Italy itself: in some other countries, and especially in this, those architects who have been of the Italian school have generally preferred the proportions and arrangements which they found in the Roman examples of antiquity, to those laid down by their Italian masters. Still, Italian church architecture of this period availed itself largely of the cupola,—certainly its redeeming feature; and the architects of Italy must have full credit for the use they have made of it, both internally and externally. Perhaps no two edifices display more, and in a greater degree, both the merits and defects of the school which produced them, than the Farnese palace and the basilica of St Peter in Rome. The principal front of the former edifice is noble in its proportions, but frittered in its details. It has an immense crowning cornice, whose general effect is certainly grand; but the mouldings are too much projected, and its vertical parts want the breadth which the blocking courses possess. The lowest of its three tiers of windows is characterised by extreme simplicity and good taste in almost every particular; but the other two are crowded with sins against both those qualities, in the dressings of the windows. The cortile and back front, though very differently arranged from the front and from each other, are filled with contrarieties, and the same may be said of the structure throughout. The front of St Peter's is not more distinguished by its magnitude than by its littleness and deformity. It contains the materials of a noble octaprostyle, and consists of an attached tetrastyle. It is divided into three unequal stories, within the height of the columns, whose entablature is surmounted by a windowed attic. In length it is frittered into a multitude of compartments, between which not the slightest harmony is maintained, while tawdriness and poverty are the distinguishing characteristics of its detail. A total absence of everything which produces grandeur and beauty in architecture, marks, indeed, the whole of the exterior of the edifice, except the cupola, than which, if its bad connection with the building out of which it grows is overlooked, architecture seldom produced a more magnificent object. Internally, the structure is open to similar praise and similar dispraise. Gorgeousness in matter and meanness in manner characterise the interior of St Peter's, except the sublime concave which is formed by its redeeming feature without. It must be said also that, probably, no building was ever erected in which the eye is so successfully deceived as to the actual dimensions. Its architect raised enormous walls, arches, and vaults, but gave every one the impression that they were on a very moderate scale. The tawdry and inappropriate sculptured decorations of the Renaissance school can nowhere be criticised with more advantage than in St Peter's. It is not too much to say that, throughout the interior, there is scarcely an ornament which is not offensive; whilst not one of them has the slightest natural connection with, or use in, a sacred building. Perhaps sculpture never reached so profound a bathos as in the hideous cherubs which are stuck, like petrified acrobats, against all the piers of St Peter's; and when we hear of such a building being treated as a model for our guidance in the completion of St Paul's, we are driven devoutly to hope that St Paul's may never in that sense be completed at all. Few people ever seem to trouble themselves to look at any part of St Peter's except the entrance front and the dome. If they would examine the rest of the exterior they would find it to be a building without one other redeeming feature, or a single grace of outline or detail, and so absolutely unscientific in its constructional arrangements as to be beneath contempt as a complete work of architecture.

St Peter's, Rome.

Cinque-cento architects.

The Cinquecento architects of Italy were extreme mannerists; but besides the manner of the school, each had his own peculiarities; so that there exists in their works what may almost be called monotonous variety. Brunelleschi's designs are distinguished by a degree of simplicity and comparative good taste, which causes regret that he had not referred more to the remains of antiquity in Italy, and sought out those of Greece, and attended less to the dogmas of Vitruvius; for then his works would have been more elegant and the school he founded would have done him much more honour. The works of Bramante possess a more classical character than those of any other architect of the school. Bramante's design for St Peter's was preferred by Pope Julius II. to a great many others by the most celebrated men of the time. He it was who suggested the cupola; but, unfortunately, after his death men of less taste and ability were allowed to alter the design, and the edifice is very different from what it would have been had Bramante been adhered to. This we judge from his works generally, and not from any positive knowledge of the design, which indeed does not exist. The elder Sangallo was far inferior to his contemporary and rival Bramante, and his works are full of the faults of the school. Michel Angelo Buonarroti was a man of great genius, but of coarse taste in architecture; and to him may be attributed many of the coarser qualities of the Italian style. His principal works are the buildings of the Capitol and the College della Sapienza in Rome, and the Laurentian Library at Florence; and these are all distinguished for their singular want of architectural beauty and propriety in every particular. Raffaelle, too, had a very bad style in architecture, and so indeed had almost all the painters after Giotto, who professed to be architects also. They generally carried to extremes all the faults of the school. Sansovino and Sanmicheli were men of considerable talent; their works display more originality and less servility than those of most of their contemporaries. Peruzzi was less employed than many who had not half his merit; his productions are with reason considered among the most classical of the Italian school. Vignola had a more correct taste than perhaps any other Italian architect of the 16th century; his works are indeed distinguishable by their superiority in harmony of composition and in general beauty of detail. Palladio very much affected the study of the antique, but his works do not indicate any appreciation of its beauties. He appears to have been very well qualified by nature for an architect, but spoiled by education. He did not look at the remains of antiquity with his own eyes, but with those of Vitruvius and Alberti, and he seems to have been too much influenced by the admired works of some of his predecessors. Palladio made greater use of insulated columns than the Italian architects generally, but his ordinances are deficient in every quality that produces beauty; his porticoes may be Vitruvian, but they certainly are not classic; and all his works show that he studied the Colosseum, the theatre of Marcellus, and the triumphal arches, more than the columns of Jupiter Stator and Mars Ultor, the temple of Antoninus and

Faustina, the Pantheon, the portico at Assisi, and the other classic models, which he drew, but clearly did not appreciate. His columns upon columns, his attached and clustered columns, his stilted post-like columns, his broken entablatures, his numberless pilasters, straggling and unequal intercolumniations, inappropriate and inelegant ornaments, circular pediments, and the like, are blemishes too numerous and too great to be passed over because of occasional elegance of proportion and beauty of detail. Scamozzi did not improve on the style of his master, which, however, he very much affected. Indeed, the term *Palladian* was long used as synonymous with beautiful and excellent architecture, so that it cannot be wondered at that Palladio's pupils and successors should have imitated him; nor is it surprising that they did not surpass, or even equal him, for they were taught to look to his works as the *ne plus ultra* of excellence. Giacomo della Porta, a contemporary of Palladio, followed Michel Angelo in several of his works, and imbibed much of his manner, on which he certainly improved; but still his own is far from being good. Della Porta was much employed in Rome; and it fell to him, in conjunction with Domenico Fontana, to put the cupola on St Peter's. Fontana's style of architecture is not particularly distinguished for its good or bad qualities: he obtained more reputation as an engineer than as an architect, having been engaged in removing and setting up most of the obelisks which give so much interest to the architectural scenery of Rome. The Lunghi, father, son, and grandson, the Rainaldi, Maderno, Borromini, Bernini, Carlo Fontana, Fuga, Vanvitelli, and many others in the course of the 17th and 18th centuries, carried the peculiarities of the Italian school to the greatest extremes. Of those enumerated, Bernini was perhaps the least offensive, and Borromini the most extravagant; but throughout that period, except in extreme cases, individual manner is less distinguishable, and that of the school more strongly marked.

It may be gathered from the preceding remarks, that the secular architecture of the Italian school is generally preferable to the ecclesiastical, and that the architects of the 15th and 16th centuries were generally superior to those who followed them. In Italy the school has not yet ceased to exist, nor indeed has its style ceased to be studied. Designs are still made by the students of the various academies in the manner of the Cinquecento, and on the models with which the country abounds. The precepts of Vitruvius are yet inculcated, and the men whose names have just been mentioned are looked up to as masters of architecture in the country which contains the Roman Pantheon and the Greek temple of Neptune at Pæstum, and has access to the more exquisite works of Greece herself.

As has been already stated, Italian architecture, though professedly a revival of the classical styles of Greece and Rome, was formed without reference to the existing specimens of either, but on the dogmas of an obscure Roman author, and the glosses of the "revivers" on his text. Vitruvius described four classes or orders of columnar composition; and on the principles which governed him in subjecting to fixed laws all the varieties with which he appears to have been acquainted, they formed a fifth, of a medley of two of his, thus completing the Italian orders of architecture. The school which was founded on the Vitruvian theories has systematised everything to an absurd extent, and laid down laws for collocating and proportioning all the matter it furnishes for architectural composition and decoration. It teaches that columns are modelled from the human figure; that the Tuscan column is like a sturdy labourer—a rustic; the Doric is somewhat trimmer though equally masculine—a gentleman, perhaps; the Ionic is a sedate matron; the Corinthian a lascivious courtesan; and the Composite an amalgam of the last two! In a composition which admits any two or more of them, the rustic must take the lowest place; on his head stands the stately Doric, who in his turn bears the comely matron, on whose head is placed the wanton, and the wanton again is made to support the lady of doubtful character! Without commenting on this, we proceed at once to point out the general features of the Italian style, premising only, that according to the practice of the school everything is confined to an exclusive use and appropriation; such columns may be fluted, and such must not; such a moulding may be used here, but not there; and so on. The proportions and arrangements of an order, of any part of one, or of anything that may come within an architectural composition, are fixed and unchangeable, whatever may be the purpose or situation for which it is required, whether, for instance, an order be attached or insulated, the column must have exactly the same number of modules and minutes in height. It is true that the masters of the school are not agreed among themselves as to those things in which they are not bound by Vitruvius; but every one not the less contends for the principle, each, of course, prescribing his own doctrine as orthodox and final on these unsettled points.

Mouldings are considered by these authorities as constituent parts of an order, and are limited to eight in number, strangely enough including the fillet. They are the cyma-recta, the cyma-reversa (or ogive or ogee), the ovolo, the torus, the astragal or bead, the cavetto, the scotia, and the fillet. They are gathered from the Roman remains, but reduced to regular lines or curves, which unlike all good artistic work may be drawn with a rule or struck with a pair of compasses. By their arrangement according to certain proportions, with flat surfaces, modillions, and dentils, a profile is formed; no two conjoined mouldings may be enriched, but their ornaments, as well as the modillions and dentils, must be disposed so as to fall regularly under one another, and, when columns occur, above the middle of them.

An order is said to be composed of two principal parts, the column and the entablature; these are divided into base, shaft, and capital in the one, and architrave, frieze, and cornice in the other, and are variously subdivided in the different orders. The Tuscan column must be made seven diameters in height, the Doric eight, the Ionic nine, and the Corinthian and Composite ten. The height of the entablature, according to some authorities, should be one-fourth the height of the column, and, according to others, two of its diameters. The parts of the entablature of all but the Doric may be divided into ten equal parts, four of which are given to the cornice, three to the frieze, and three to the architrave; and in the Doric, the entablature being divided into eight parts, three must be given to the cornice, three to the frieze, and the remaining two to the architrave. For the minor divisions a diameter of the column is made into a scale of sixty minutes, by which they are arranged; but this is obviously irrelevant if the whole height of the entablature is determined by the height of the column, and not by its diameter; in this case, therefore, they must be proportioned from the general divisions already ascertained. Columns must be diminished, according to Vitruvius, more or less as their altitude is less or greater,—those of about fifteen feet high being made one-sixth less at their superior than at their inferior diameter, while that proportion is lessened gradually, so that columns fifty feet high shall be diminished one-eighth only. On this subject, however, many of his disciples controvert the authority of their master; and some of them have fixed the diminution at one-sixth of a diameter for columns of all sizes in all the orders. The entasis of columns is disputed also, some authorities making it consist in preserving the cylinder perfect one-quarter or one-third the height of the shaft from below, diminishing thence in a right line to the top; while others, following Vitruvius, make the column increase in bulk in a curved line from the base to three-sevenths of its height, and then diminish in the same manner for the remaining four-sevenths, thus making the greatest diameter near the middle.

It being difficult to determine among the masters of the Italo-Vitruvian school whose designs of the various orders are to be preferred, we have selected those of Palladio, certainly not for any superior merit they possess, but because he is more generally esteemed than any other, and because he the most strictly adhered to the precepts of Vitruvius, as far as he could understand them. It should be remarked however, that although Palladio recommended fluting all but the shaft of the Tuscan column, he very seldom fluted columns in his own practice; and indeed it was the custom of the Italian school not to flute, whatever their doctrine may be to the contrary; for fluted columns in Italian architecture are exceptions to the general practice. Swelled or pillowed friezes are not peculiar to Palladio; they are more or less common to the works of most of the masters of the same school. Prostyles being almost unknown in Italian architecture, antæ are not often required; but when they are, the meanest succedaneum imaginable is recurred to. Of this Palladio's Villa Capra near Vicenza and Lord Burlington's Palladian villa at Chiswick afford striking examples. Pilasters, however, are very common, so common, indeed, that they may be called pro-columns, as they are often used as an apology for applying an entablature. They are described as differing from columns in their plan only, the latter being round, and the former square; for they are composed with bases and capitals, are made to support entablatures according to the order to which they belong, and are fluted and diminished with or without entasis, just as columns of the same style would be. When they are fluted, the flutes are limited to seven in number on the face, which, it is said, makes them nearly correspond with the flutes of columns; and their projection must be one-eighth of their diameter or width when the returns are not fluted; but if they are, a fillet must come against the wall. Pedestals are not considered by the Italo-Vitruvian school as belonging to the orders, but they may be employed with them all, and have bases and surbases or cornices to correspond with the order with which they may be associated. The dado of a pedestal must be a square whose side shall be equal to that of the plinth of the column or pilaster which rests on it, or a parallelogram a sixth or even a fourth of a diameter taller. The intercolumniations of columns are called pycnostyle, systyle, eustyle, diastyle, and aræostyle, and are strictly adhered to in Italian architecture when columns are insulated, which is not very often; when they are attached, the interspaces are not limited, except when a peculiar arrangement called aræostyle is adopted. This consists of two systyle intercolumniations, the column that should stand in the mid-distance between two others being placed within half a diameter of one of them, making, in fact, coupled columns or pilasters. It is applied to insulated columns as well as to those which are attached. Following Vitruvius, the Italian school makes the central intercolumniation of a portico wider than any of the others. The height of arched openings, in arcades or elsewhere, is generally about twice their width; if, however, they are arranged with a columnar ordinance, having columns against the piers, they are made to partake of the order to which the columns belong, being lower in proportion to their width with the Tuscan than with the Doric, and so on; and the piers are allowed to vary in the same manner, from two-fifths to one-half of the opening. With columnar arrangements, moulded imposts and archivolts are used; the former being made rather more than a semi-diameter of the engaged columns in height, and the latter exactly that proportion. Variously moulded keystones are used, too, projecting so that they give an appearance of support to the superimposed entablature. Smaller columns with their entablature are sometimes made to do the duty of imposts, and sometimes single columns are similarly applied; at other times, columns in couples are allowed to stand for piers to carry arches. In plain arcades the masonry is generally rusticated, without any other projection than a plain blocking course for an impost, and a blocking course or cornice crowning the ordinance. Niches and other recesses are at times introduced in the plain piers, which are in that case considerably wider than usual, or in the spandrels over wide piers. Very considerable variety is allowed in these combinations. Doors and windows, whether arched or square, follow nearly the same proportions, being made, in rustic stories, generally rather less than twice their width in height, and in others either exactly of that proportion, or an eighth or a tenth more. If they have columned or pilastered frontispieces, these are sometimes pedimented; and, except in rustic stories, whether with or without columns, a plain or moulded lining called an architrave is applied to the head and sides of a door or window. This architrave is made from one-sixth to one-eighth the width of the opening it bounds, and it rests on a blocking course or other sill, as the case may be. In the absence of columns or pilasters in the frontispiece, their place is frequently supplied by consols or trusses of various form and arrangement, backed out by a narrow pilaster, which may be considered as the return of the frieze of the entablature, and which supports the cornice. It is not uncommon for the architrave lining to project knees at the upper angles, and this is sometimes done even with consols and their pilasters. With columned frontispieces to gateways, doors, and windows, arose the custom, so frequent in Italian architecture, of rusticating columns, by making them alternately square and cylindrical, according to the heights of the courses of rustic masonry to which they are generally attached, and with which they are less offensive than in other collocations. The practice of the Cinquecento school of piling columns on columns with their accessories is warranted by the doctrine of its master; but his precepts not being practicable, recourse has been had to the inferior works of the Romans, which present examples of it. The difficulty of preserving anything like a rational arrangement is acknowledged on all hands to be great, if not insurmountable; for if the first or lowest order be at an intercolumniation fitting its proportions, the second or next above it, though diminished ever so little, is already deranged, for it has the same distance from column to column that the inferior order has whilst the columns themselves are smaller in diameter, and their entablature consequently shallower. This derangement must, of course, increase with every succeeding ordinance, rendering it indeed impossible to make such a composition consistent. The most approved practice in arranging order above order appears to be, that the upper column shall take for its diameter the superior diameter of the one below it; that when the columns are detached their axes shall be in the same perpendicular line; but when attached or engaged, the plinth of the pedestal of the upper shall impend the top of the shaft of the lower column. The most rational mode, however, for diminishing, if reason can be applied to such compositions, is to carry the diminution through, the outlines of the columns of the lowest order being drawn up in the same direction, and so the columns of every story would take up their place and

be diminished in regular gradation. When columns are attached, or pilasters are used, in Italian architecture, the almost invariable custom is to break the entablature over every column or pilaster, or over every two when they are in couples. Because of the great length of the intercolumniation, this would appear to have been done at first; but it has frequently been done by some of the most distinguished practitioners of the school, even without that excuse, so that it may be held as approved by them. A basement is either a low stereobate or a lofty story, according as it is intended to support a single ordinance the whole height of the main body of the structure, or indeed the lowest of two or more orders; or as it occupies the ground story of a building, and supports an ordinance, or the appearance of one, above. In either case much is necessarily left to the discretion of the architect; but in the latter the height of the order it is to support is the generally prescribed height of the basement. A basement may be rusticated or plain; if it be low, and is not arranged like a continued pedestal, it must have neither cornice nor blocking course; but if lofty, a deep bold blocking course is indispensable. An attic may vary in height from one-quarter to one-third the height of the order it surmounts; attics are arranged with a base, dado, and coping cornice, like pedestals, and generally have pilasters broken over the columns below. The rule for the form, composition, and application of pediments in Italian architecture, if it may be gathered from the practice of the school, appears to be to set good taste at defiance in them all. We find pediments of every shape, composed of cornices, busts, scrolls, festoons, and what not, and applied in every situation, and even one within another, to the number of three or four, and each of these of different form and various composition. The proportion laid down for the height of a pediment is from one-fourth to one-fifth the length of its base, or the cornice on which it is to rest. Balustrades are used in various situations, but their most common application is in attics, or as parapets on the summits of buildings, before windows, in otherwise close continued stereobates, to flank flights of steps, to front terraces, or to flank bridges. Their shapes and proportions are even more diversified than their application; that of most frequent use is shaped like an Italian Doric column, compressed to a dwarfish height, and consequently swollen in the shaft to an inordinate bulk in the lower part, and having its capital, to the hypotrachelium, reversed to form a base to receive its grotesque form. The base and coping cornice of a balustrade are those of an ordinary attic, or of a pedestal whose dado may be pierced into balusters. The general external proportions of an edifice, when they are not determined by single columnar ordinances, appear to be unsettled. The grand front of the Farnese Palace in Rome is in two squares, its length being twice its height; the length of each front of Vignola's celebrated pentagonal palace of Caprarola is two and a quarter times its height above the bastions. In Palladio's works we find the proportions of fronts to vary so considerably as to make it evident that he did not consider himself bound by any rule on that point. In some cases we find the length to be one and a sixth times the height, in others one and a fourth, one and a half, two, two and a sixth, and even three and a sixth; and elevations by other masters of the school are found to vary to the same extent. The proportions of rooms, again, range from a cube to the ratio of one to two, though it is preferred that the height should be a sixth, or even a fifth, less than a side when the plan is a square; but the sesquialteral form, with the height equal to the breadth, and the length one-half more, is considered the most perfect proportion for a room. There is considerable variety and beauty in the foliate and other enrichments of an architectural character in many structures in Italy, but very little ornament enters into the columnar composition of Italian architecture. Friezes, instead of being sculptured, are swollen; the shafts of columns, it has been already remarked, are very seldom fluted, and their capitals are generally poor in the extreme; mouldings are indeed sometimes carved, but not often; rustic masonry, ill-formed festoons, and gouty balustrades, for the most part supply the place of chaste and classic enrichment. This refers more particularly to the more *classic* works of the school; in many of the earlier structures of Italy, and especially on monuments of various kinds, we find what may be called a graceful profusion of ornament, of the most tasteful and elegant kind; few carved mouldings however, and very few well-profiled cornices, are to be met with in Italian compositions of any kind. In many of the later architectural works of that country we find again a profusion of ornament of the most tasteless and inelegant description, chiefly in the gross and vulgar style, which is distinguished as that of Louis XIV. of France.

In the 15th century such was the reverence of men for the revived works of ancient literature and science, that the pretence of the Italians, that they had restored ancient classical architecture on the precepts of an architect of the Augustan age, was sufficient to open the way for them all over civilised Europe. In the course of that and the following century Italian architecture was adopted and Italian architects employed in France, Spain, Germany, Great Britain, and their respective dependencies; and now, in the 19th century, Vitruvius and Palladio are as predominant on the shores of the Baltic as on those of the Mediterranean; though in England and in some parts of the Continent their influence is considerably diminished since the time of Inigo Jones and Claude Perrault. It has been already remarked, too, that the Cinquecento was later in gaining a footing in Britain than on the Continent, in consequence of the love of the beautiful national style of architecture, which our ancestors do not appear to have been induced to resign to the barbarian innovators of the South, as readily as most other nations were to give up theirs. The French, though they received the Vitruvian architecture from the Italians, were patriotic enough, as soon as they had acquired its principles, to confine the practice of it almost entirely to native architects, in whose hands it assumed a different character from that which it possessed in Italy, and became what may be called the French style of Cinquecento. Its ecclesiastical structures are less faulty than are those of the corresponding period in Italy, but its secular edifices are as far inferior to those of that country. The grand palatial style, which is exemplified in the Farnese Palace in Rome, never found its way into France; but instead, there arose that monstrous and peculiarly French manner, of which the well-known palaces of the Tuileries and Luxembourg are egregious examples. In the age of Louis XIV. the French appear to have reverted to the Italian manner in a certain degree; for the palace of Versailles includes almost all the extravagances of that school in its worst period, and contains, moreover, architectural deformities which Italy never equalled till it imitated them. They consist in the style of enrichment which is distinguished by the name, and is due in part to the gross taste, of the monarch in whose reign it had its origin. The same period produced one of the most classical architects of the French school—its Palladio or Inigo Jones—Perrault, whose design for the buildings of the Louvre was preferred to that of Bernini, though, indeed, the preference was no compliment to the one nor discredit to the other, considering to whom the decision was of necessity referred. The Hotel des Invalides is of the same age: it exhibits the graces of the Italian cupola, surmounting a composition which includes more than all the faults of St Peter's in

Rome. The church of Sainte Genevieve, or the Pantheon, a work of the following reign, was intended to be in the ancient Roman style, and of Roman magnificence; but it is rather papally than imperially so. Ancient Rome was regarded in the columnar ordinance, but modern Rome in the architectural composition. In it the ecclesiastical style of the Cinquecento is commingled with the simple beauties of Roman architecture, almost, indeed, to the destruction of the latter, and it is crowned by a too lofty cupola. More recently the works of the ancients have been studied by the architects of France, greatly to the amelioration of their style, although many of them still appear to disregard the peculiarities of real Greek architecture, and to retain their devotion to Vitruvius and the 15th century. Spain received but soon modified the Italo-Vitruvian architecture, and has never recovered from the architectural excesses into which her architects plunged when the wealth of their countrymen in the 16th and 17th centuries enabled them to accomplish such enormous works. Of these, the man of the greatest fame out of his own country is Herrera, the architect of the Escorial, a vast palace built upon the ingeniously rural plan of a gridiron. It is a vast but bare, cold, and repulsive building. Not less is the cathedral at Valladolid a grand failure, though Herrera must be credited with much more self-restraint and reserve in the use of ornament than the Italian architects of his own time, and some of his contemporaries and successors in Spain. One of the most famous of these, Churriguerra, gave his name to a fashionable style which was neither more nor less than the most *rococo* travesty of Italian Renaissance that could be invented; and another school of architects, imitating the delicate chasing of silversmiths' work, produced another variation of the style, which was christened "Plateresque." If this is less cold than Herrera's work, and less offensive than Churriguerra's, it contains at the same time none of the elements of a really great and lasting style of architecture, and is only interesting as a local variety of style. The Italian revival was the means of extinguishing the Pointed style of architecture in Germany, and certainly without affording it an equivalent. Italian architects were employed in Germany, and Germans acquired their manner; but they did not improve it, nor did they make it productive of so many good effects as the Italians themselves did. The change in religion which followed the change in architecture in so large a part of Germany may have tended to prevent the latter from acquiring that degree of exuberance there which it reached in Italy; but even in Catholic Germany the splendid Pointed cathedrals have never given way to modifications of the pseudo-classic St Peter's. In the use of Cinquecento architecture for secular structures, it may be truly said that the Germans have not excelled the Italians, nor, on the other hand, have they equalled them in the absurdities and extravagances which are so frequently observable in the works of some of the latter. The Germans also have turned their attention to the works of the ancients, and the fruit of this is evident in many parts of the country, particularly in Prussia; still, however, they have yet to show that it is possible to apply the Greek models to modern uses, and to exhibit a proper sense of the exquisite perfection of their detail, as well as to emancipate themselves from the trammels of the Vitruvian school. The northern Continental nations have been dependent for their architecture on Germany, France, or Italy, and can produce nothing that gives them a claim to consideration in such a review as the present. St Petersburg is exclusively the work of architects of the nations just enumerated, and presents a mass of the merest common-places of Italian architecture, in structures calculated by their extent only, like Versailles, the Escorial, and St Peter's, to impose on the vulgar eye.

Modern English Architecture.

We have already more than once had occasion to refer incidentally to the introduction of Cinquecento architecture into Britain; and in noticing it more particularly, and tracing its course, we are saved the trouble of keeping up a distinction between the different parts of our triple nation, because at the time it actually crossed the Channel the union of the kingdoms had taken place.

When the Pointed style received its deathblow in England, in the reign of Henry VIII., it did not immediately cease to exist; nor was it immediately succeeded by the Italian when it became extinct. It was gradually declining through all the 16th century, during the latter part of which period what has been called the Elizabethan style became somewhat permanent. It consists of a singular admixture of the Italian orders with many peculiarities of the Pointed style, and in many examples the latter appears predominant. With such difficulty, indeed, did that fascinating manner give up its hold on the minds of men in this country, that the Cinquecentists appear to have relinquished the hope of effecting its destruction, unfortunately, however, not until the injury was done; and for some time we were left without a style of any kind, unless that may be called by the name which marks the edifices of the reign of James I., and of which the oldest parts of St James's Palace are a specimen.

The destruction of the Pointed style has been referred by some to the change in religion which took place under the Tudor line of English monarchs, but certainly without sufficient reason. It was the "Reformation" of architecture in Italy, and not that of religion in Great Britain, that effected it; and it may be doubted whether the change would not have taken place sooner in this country if its connection with Italy had not been so materially affected by the moral change here; for it was Germany and France that supplied us with architectural reformers during the reigns of Henry VIII. and his children, and not Italy, whose professors might possibly have obtained more credit than their disciples did.

So dilatory were we, indeed, in the cultivation of the Italian style, that the first professor of it who was actually employed on edifices in this country came to it from Denmark! It is true he was an Englishman; but so little hope did he appear to have of success at home, that he accepted an invitation from the king of that country. He had gone to Venice to study painting; but becoming enamoured of architecture, as he saw it in the works of Palladio, he had made that his study instead, and had already acquired considerable reputation in that city when Christian IV. of Denmark invited him to his court to occupy the post of his first architect. A train of circumstances brought him to England a few years after James I. came to the English crown, and he was appointed architect at first to the queen, and subsequently to Henry prince of Wales. But this does not appear to have then obtained employment for him, since after the death of the prince he went again to Italy, where he remained till the office of surveyor-general, which had been promised him in reversion, fell vacant. This was the celebrated Inigo Jones, who has been called the English Palladio; and, indeed, he succeeded so well in acquiring the peculiar manner of that architect, that he richly deserves whatever credit the appellation conveys. It is unfortunate, however, for his own reputation, that he had not looked beyond Palladio and their common preceptor Vitruvius to the models the latter pretends to describe; in which case he might have been the means of solving the question whether the truly classical architecture of the ancients could ever be introduced here with any advantage. But instead of that he brought nothing home but Italian rules and Italian prejudices. Jones commenced the truly Gothic custom of thrusting Cinquecento fittings into our Pointed cathedrals, by putting up an Italian screen in that of Winchester; and he barbarised the ancient cathedral of St Paul in London, by repairing it according to his notions of Pointed architecture, whilst at the same he defaced its exterior by affixing to it an Italian front. Of the Palladian style, however, he was a complete master. He designed a royal palace, which was to have been built at Whitehall, in a manner as far superior to those of Versailles and the Escorial as the works of Palladio are to those of Borromini. The only part of Jones's design ever executed is the structure called the Banqueting House, whose exterior is an epitome of many of the faults, and most of the beauties of the Palladian school. It rises boldly from the ground with a broad, simple, and nearly continuous basement, or stereobate, and the various compartments of its principal front are beautifully proportioned; but though the circular pediments to the windows, the attached unfluted columns, with broken entablatures and stylobates, the attic and balustrade, be the materials of Palladian, it may be confidently denied that they are consistent with classical, architecture. Another well-known work of this architect is the Italo-Vitruvian Tuscan church of St Paul, Covent Garden, whose eastern portico is well-proportioned in general, but grossly deformed in detail, and whose interior was left to take care of itself, having absolutely no charm either of proportion or detail.

Architecture was in abeyance in this country, again, from the troublous times of Charles I. till the restoration of the monarchy in the person of his son, whose French taste would have completely Gallicised the architecture of the nation, if the genius of Sir Christopher Wren had not been present to avert the infliction, or rather to modify it; for it cannot be denied that the influence of the French manner had an effect on the architecture of this country from that period down to the middle of the last century. Indeed, Wren himself knew the stylo he practised mainly from books and the structures of France; and, in consequence of his visit to France, the peculiarities of the French style are obvious in many of his less esteemed works. Fortunately, however, he was proof against the grosser peculiarities of the Cinquecento, whether in the books of the Italians or in the edifices of the French; and his own productions show that he had imbibed much of the spirit of the antique monuments of Italy, which he could have known only from engravings, and those very imperfect ones. The field that was opened to his genius by the great fire of London in 1666, and its result, are equally well known. It is true that the general absence of taste and feeling with regard to the Pointed style extended even to him. Wren was guilty of many offences in that respect, besides giving authority to the opprobrious term Gothic; and in no case more so than in the construction of the towers added to Westminster Abbey, which are a lasting proof of his ignorance of its most obvious principles. Nevertheless, to the influence of our beautiful native style on his mind the architecture of his period is indebted for some of its best works. If Wren had not been accustomed to contemplate the graceful and elegant pyramids or spires of his native country, he would never have originated the tapering steeple, in the composition of which with the materials of Italian architecture he still stands as unrivalled as he was original. Witness the steeples of Bow Church and St Bride's in London, the former of which is hardly surpassed in grace and elegance by the pointed spires themselves. It must remain a constant subject of curious speculation, what effect would have been produced on this great head of the English school of Cinquecento architecture if he had known the remains of ancient Greece and Rome from personal observation. With his splendid genius and fine taste, if he had not been imposed on by the specious pretence of the Italo-Vitruvian school, his works might have been models for imitation and study, as they are objects of admiration; as it was, he avoided many of the faults of that school, and improved on many of its beauties. Although he did not know the Greek style at all, and knew the Roman only through imperfect mediums, and, indeed, had never seen an example of either, whenever he has varied from the Italian practice it has been towards the proportions and peculiarities of the Greek! The great west front of St Paul's, though it is said to be imitated from that of St Peter's in Rome, or rather from what it was proposed to be, with the two towers to form its wings, is a much finer, a more imposing, and more classical specimen of architecture than its prototype; for the advantage the latter should have in being of columns in one height is lost entirely in their poverty, and in the miserable arrangement of the whole front, whereas that of St Paul's is in two noble pseudo-prostyle and recessed porticoes, with the columns fluted, and generally conceived and executed in much better taste than those of St Peter's. The entablatures, though massive, are finely proportioned, and sufficiently ornate to be elegant; they are, too, quite continuous, and the upper one is surmounted by a noble pediment, whose pyramidal form gives at the same time dignity and a finished appearance to the whole front. The coupling of the columns, however, and the putting of one columnar ordinance over another, can only be defended by the practice of the Italian school; though, in the present case, both are rendered less offensive by the judicious management of the architect. Nothing shows more strikingly the superiority of St Paul's to St Peter's as an architectural composition, than a parallel of their flanks. The great magnitude of the latter may strike the vulgar eye with admiration in the contrast; but the rudest taste must appreciate the surpassing merit of the former in the form and arrangement of the cupola, and the noble peristyle, with its unbroken entablature and stylobate, out of which it rises, when compared with the sharper form and depressed substructure of that of St Peter's. The superiority of St Paul's in the composition of the main body of the edifice is not less in degree, though, perhaps, less obvious, than in the superstructure. In the one it is broken and frittered, and in the other almost perfectly continuous, in broad, bold, and effective masses.

The history of the works of Sir Christopher Wren is the history of the architecture of the period in this country; and as it must be admitted that he was not so successful in the composition of the architecture of secular structures as of ecclesiastical, it will follow that our secular edifices of that time are of inferior merit. If it were not indeed an historical fact, it would hardly be credited that Chelsea College, the old College of Physicians in London, and the halls of some of the city companies, are by the architect of Bow Church and St Paul's.

The style introduced by Sir John Vanbrugh, who may be said to have succeeded Sir Christopher Wren in the direction of architecture in England, was distinguished by massiveness unsuited to the style in which he built, which was, of course, Italian. It was, however, free from the extravagances which characterise that style generally in other countries at the same period, but was certainly more suited to the soberer character of ecclesiastical than of secular structures, whereas his principal works were noblemen's mansions. Vanbrugh's faults were generally those of Michel Angelo; he was a painter architect, and did not understand beauty of proportion and detail so well as the pictorial arrangement of lights and shadows,—to produce which in the Cinquecento it is almost necessary to part with all the higher beauties of architecture. Hawksmoor added to the style of his master that noble ornament in which Italian works are so very deficient—a prostyle portico. His compositions are marked by severe simplicity, and only want to be absolved from a few faults and enriched with a few elegances to be among the best of modern times. Not the least distinguished architect of the same age (the first half of the 18th century) was the earl of Burlington, who was a passionate admirer of the style of Palladio and Inigo Jones. Many of the edifices erected by Kent are asserted to be from the designs of that nobleman, who, with considerable talent, was, however, a somewhat bigoted devotee to Vitruvius and the Cinquecento generally, as well as to Palladio in particular; for he frequently used columns representing half-barked trees in conformity with the silly tales of Vitruvius, and the sillier whims of his disciples. The portal of his own house in Piccadilly, and that of the King's Mews, were special examples of this bad taste, and of other faults of the school besides. Lord Burlington built for himself at Chiswick a villa on the model of the Villa Capra, or Rotonda, near Vicenza—a structure which has been called the master-piece of Palladio. In form and proportion it is certainly elegant, but its details strongly exhibit the poverty of Italian columnar architecture, when unaided by the frittering which is its bane, and almost its only element of effect. Gibbs, a contemporary, had, like Hawksmoor, imbibed a taste for the classic prostyle portico, which he evinced in St Martin's Church in London; but that he also was in the trammels of the Italian school is no less evident, in the same structure, to a considerable extent, and still more so in the church of St Mary in the Strand, which is a mediocre specimen of architecture, though a favourable one of its style. During the following half-century (the latter half of the 18th) Sir William Chambers and Sir Robert Taylor were the most distinguished architects of this country. They were both men of genius and skill, who had availed themselves of the remains of Roman antiquity to good purpose (for as yet those of Greece were either unknown or unappreciated), and the former has left us, in the Strand front of Somerset House in London, perhaps the best specimen of its style in existence. Other parts of the same edifice, however, are far from deserving the same degree of praise; indeed, as an architectural composition, the river front is altogether inferior in merit to the other, though of much greater pretence. The inner fronts to the great quadrangle, though exhibiting good parts, are, as a whole, not above mediocrity. An air of littleness pervades them; and the general effect of the fronts themselves is made still worse by the little clock towers and cupolas by which they are surmounted; and to this may be added the infinity of ill-arranged chimneys, which impart an air of meanness and confusion that nothing can excuse. While Sir William Chambers and a few others were applying the best qualities of Italian architecture, indeed, improving its general character, and, it may be said, making an English style of it, there were many structures raised in various parts of the country in a manner hardly superior to that of the time of James I.,—structures in which all the meanness and poverty of the Cinquecento are put forth, without any of its elegance of proportion, or that degree of effectiveness which men of talent contrived to give it. During the same period, too, the seeds of a revolution were sown, which almost succeeded in ejecting the Italian style and its derivative from this country, without perhaps having furnished a complete equivalent.

In the year 1748 James Stuart and Nicholas Revett, two painters pursuing their studies in Rome, having moreover paid some attention to architecture, issued "Proposals for publishing an accurate description of the Antiquities of Athens, &c." These proposals met with general approbation, and in consequence they determined on prosecuting their plan; but various hindrances prevented their arrival in Athens till March 1751, when they commenced measuring and delineating the architecural monuments of that city and its environs. In this work they were unremittingly employed (as far as their own exertions went, for they were frequently interrupted by the Turks) for several years, so that they did not reach England with the result of their labours until 1755; and, by a series of almost unaccountable delays, the first volume of their work did not appear until the year 1762. Sixteen years more expired before the second issued from the press; and the third was not published until 1794, being nearly fifty years from the time the work was first announced! In the meantime a Frenchman of the name of Le Roy, who was at Rome when our countrymen issued their proposals, had gone to Athens, and collecting in a very short time some loose materials, had published at Paris, in 1758, a work which he called *Les Ruines des plus beaux Monumens de la Grèce, &c.*, in which he makes not the slightest mention of Stuart and Revett, or of their labours or intentions, with all of which he was well acquainted. This work is, moreover, notoriously and grossly incorrect,—so incorrect, indeed, as to make it difficult of belief that its author ever saw the objects of which he professes to give the representations. It was, however, from M. le Roy's work that the public had to judge of the merits and beauties of Greek architecture; for the first volume of Stuart and Revett's *Antiquities* did not appear for several years after it, and that does not contain any pure specimen of the national or Doric style: the second, which does, was not published for twenty years after Le Roy's. Considering, therefore, the source of information on the subject, it can hardly be wondered at that Greek architecture was vituperated on all sides; and by none with greater acrimony than by Sir William Chambers, whose apology must be ignorance and the prejudices of education. He really did not know the style he carped at; and his education in the Italo-Vitruvian school had unfitted him for appreciating its grand, chaste, and simple beauties, even if he had known it. Notwithstanding the misrepresentations of Le Roy, the vituperations of Chambers, the established reputation of Italian architecture, and the trammels which Vitruvius and his disciples had fixed on the public mind, when Stuart and Revett's work actually appeared, the Greek style gradually advanced in esteem, by its intrinsic merits alone—for it has had no factitious aids; and since that period, Greece and all her colonies which possess remains of her unrivalled architecture have been explored, and we now possess correct delineations of almost every Greek structure which has survived, though in ruins, the wreck of time and the desolation of barbarism. To our country and nation, then, is due the honour of opening the temple of Greek architectural art, of drawing away the veil of ignorance which obscured the beauties it contains, and of snatching from destruction, and consequent oblivion, the noble relics of ancient architecture which bear the impress of the Grecian mind. Not only, indeed, were we the first to open the mine, but by us it has been principally worked; for among the numerous treatises on the Hellenic remains which now exist, by far the greatest number, and indisputably the most correct, are by Englishmen, and have been published in England. It required, however, a generation for the effects of ignorance and prejudice in some, and imperfect knowledge in others, to wear away before any effects of the study of the Greek style could be obvious in our structures. The works of the Adams, who were the contemporaries and immediate successors of Sir William Chambers, evince a taste for the beauties of Greek architecture, but a very imperfect knowledge, indeed, of the means of reproducing them. The architects who had the direction of our principal works during the earlier part of this century had the disadvantage of being pupils of those who were themselves, as we have shown, incompetent to appreciate the Greek style; and at a time, too, when the state of Europe prevented all access to the remains of Greece and Rome, so that no great improvement could perhaps be expected from them. Personal study of the monuments they wish to rival is the absolute duty of all architects, and it is possible that study even of the older examples may in all cases teach them some useful lesson. The structures of Egypt may show us how to arrange large masses harmoniously and effectively, those of Greece and Rome how to impart grace and dignity. The structures of Italy show us how far the materials of ancient architecture may be moulded to modern uses, while at the same time they give practical warning of what may result from the abuse of the most obvious principles of the art, and from the neglect of our national style or the requirements of our own country and climate, with which it is almost unnecessary to say it is quite impossible to harmonise the works of so entirely different a climate as that of Greece.

The difference between the representations of the Athenian antiquities by Stuart and his colleague, and the misrepresentations of them by Le Roy, appears to have opened the eyes of the world to those of ancient Rome, to see if they too had not been dealt with unjustly; for much more correct delineations of them had appeared than those of Palladio and Desgodets,—delineations of them as they exist, exhibiting the spirit of the originals, and not warped to the Vitruvian precepts, and thereby stripped of their best quality, truth. The excavation of the ancient cities of Herculaneum and Pompeii has opened to us much interesting and instructive matter, and their ruins have now been correctly delineated.

It is an argument in proof of the classical beauty of the Pointed style, that when the eyes of men were opened to the perfections of Greek architecture, they began to discover its merits also. Pointed architecture, under the opprobrious name Gothic, had long been a subject of discussion among antiquaries,—that is, essays were written by them to prove how the pointed arch originated, but none appreciated its beauties. Our Pointed cathedrals and churches were, after the example of Inigo Jones, ruthlessly barbarised in course of repairing and fitting them up. If an architect were employed to do anything about one of them, he appears to have thought it incumbent on him to convert it to the doctrines of his own faith—to Italianise it. Deans and chapters for the most part entrusted their commissions to country masons and plasterers, who also operated according to the laws of the "five orders." About the middle of the 18th century one Batty Langley endeavoured to draw the attention of the world to Pointed architecture, by reducing it to rules, and dividing it into orders. Fortunately he was only laughed at, and both he and the book he published on the subject were soon forgotten. One of the first men in rank and influence of his time, in matters of taste particularly, Horace Walpole, *patronised* Pointed architecture, but ineffectually. He had himself neither taste nor feeling to appreciate its beauties, as his Strawberry Hill clearly shows. Delineations were indeed put forth from time to time, but generally so rude and imperfect, that they did more harm than good. The Society of Antiquaries, however, at length took up the subject, engaged Mr John Carter, an ardent and judicious admirer of our national architecture, and commenced the publication of a series of splendid volumes, containing engravings of its best specimens, from drawings and admeasurements by him. The *Antiquities of Athens* had already done much to dispossess men of their prejudices, by showing that Greek architecture, though neither Vitruvian nor Palladian, was nevertheless beautiful; and the great work of the Society of Antiquaries did the same for Pointed architecture. Since the death of Mr Carter our national buildings have been studied, catalogued, drawn, and published by an infinity of admirers, who have done their work with zeal which has been thoroughly enthusiastic. The works of the elder Pugin were the first to show how architecture ought to be drawn, whilst the work of Mr Rickman was the first to show how it ought to be studied. From the time of these two pioneers in the work, it would be impossible to catalogue a hundredth of the works which have been devoted to the subject. Nor have they been written by architects only. On the contrary, a large number of them are the work of amateurs, and it may be truly asserted that never since art has been written upon at all have so vast a number of publications, on every branch of it, been given to the world as within the last thirty years have been devoted to the illustration and history of our national Gothic architecture. Germany and France have been equally prolific on the same subject, and the only difficulty now is, out of the mass of materials how to select that which is useful and to the point. In Spain and Italy no such zeal has been shown, and the elucidation of their mediæval antiquities has been left almost entirely to foreign hands.

Saracenic Architecture.

The beautiful forms by which Saracenic or Arabian architecture is best known were wrought into a style, if they were not invented, by the descendants of the wild Arab tribes who accepted Mahomet as their leader and prophet. In estimating their influence upon architecture,

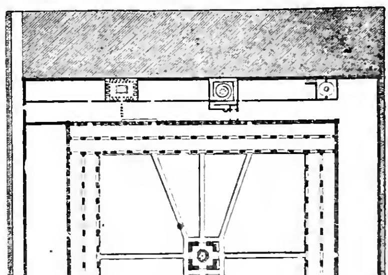

Fig. 46.—Plan of Mosque of Tooloon, Cairo. From Costo's *Architecture Arabe en Caire.*

the first point to be considered is whether the Arabs, as they emerged from their deserts and overran the rich countries of Syria, Persia, and Egypt, brought with them any art of their own, or whether they formed their style after their conquests were secured, when they had become great, and had consequently leisure and power to form it by the aid of foreigners. Now, in the Koran no notices are found that would lead us to suppose that any definite

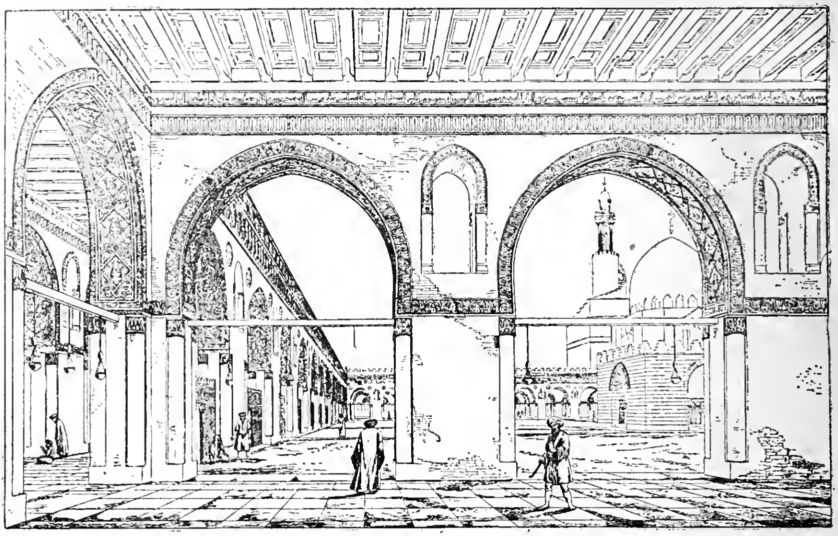

FIG. 47.—Court of the Mosque of Tooloon, Cairo. From Coste.

forms of art were known to the Arabs in early times. We gather also that the minaret, one of the most prominent and beautiful forms of their architecture, could not have been used in early times, since we are told that the call to prayers was then made from the roofs of the mosques.

The earliest example of a mosque in Arabia itself is supposed to have been that at Mecca, 705 A.D. But this was rebuilt in the 15th century, and that of Medina in the 16th, and we have no definite account of the original structures. The earliest of those which still exist are the Mosque of Amrou at Cairo (about 642 A.D.), and that of Damascus (705). Both of these were built of columns, &c., obtained by the destruction of Roman work.

In the Mosque of Tooloon at Cairo we find for the first time anything original. It was constructed about 879, and is said to have been designed by a Christian architect. Indeed, numerous passages in the early history of the Saracens seem to show that their architects and art workers generally were foreigners, attracted from Baghdad, Byzantium, and other places. It was the same throughout their progress in Spain as well as in Egypt; and however that style was eventually formed, which has given to us the beautiful domes and minarets of Cairo, the Alhambra in Spain, and the houses of Algiers, there can be little doubt but that it was based upon the art of Persia and Byzantium.

Ultimately it developed into two very distinct forms,—the Arabic of Cairo and the Moorish of Spain. But these still showed themselves, both in general form and in details, to be members of the same great family which we now call Saracenic. The chief structures in this style are the mosques and tombs. The former are very simple in plan, consisting, usually, of a mere open space with colonnades round and with a prayer niche (*mehrab*) in the side

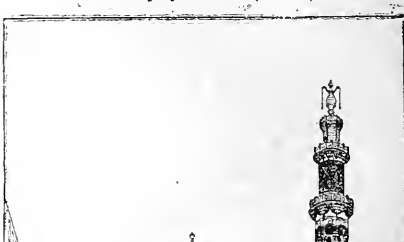

FIG. 48.—Exterior view of Kaid Bey Mosque, Cairo. From Coste.

towards Mecca. Near this was a pulpit (*mimbar*), and as this part of the edifice was of course the most frequented, the colonnades were made of extra depth. In the centre of the court was a fountain, just as in the atrium of the Christian basilicas; and conspicuously, sometimes at each corner of the mosque, was placed a minaret. The size of the whole and the number and richness of the columns might

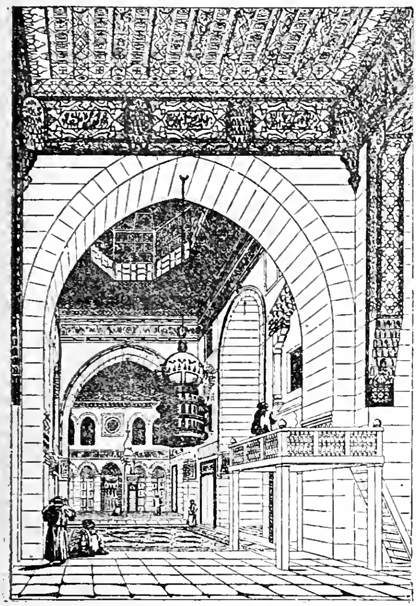

FIG. 49.—Interior view of Kaid Bay Mosque. From Coste.

vary, but the general arrangement was nearly always the same, the really essential parts being the prayer niche, the pulpit, the fountain, some protection against the burning noonday heat, and some elevated place from which the priest could call to prayers. A remarkable exception to the ordinary plan occurs in the celebrated Mosque Soultan Hassan at Cairo, which is in the form of a cross, the four arms being arched over, whilst the centre is left open and contains the usual fountain. Closely connected with the mosque is, often, the tomb of its founder. This is nearly always covered with a dome which, when on a large scale, was almost invariably a sign of a sepulchral edifice.

In these mosques and tombs we meet with general forms and details unknown elsewhere in Western art at the time of their erection. First of all we meet with the pointed arch. Very early in the style, and long before the era of Pointed architecture, this arch was used by the Saracens. But peculiar to their art are the beautiful minarets. Springing from a square base, they were gradually brought to an octagon or a round with a corbelled gallery at every change, and each part ornamented by diaper work of the most elaborate kind. The domes are equally varied and beautiful. They spring from a square base, and are gathered into the usual circular form in the most graceful manner. Quite opposite also to the Western mode, the external surfaces of the domes are sometimes decorated with diaper or other work, beautiful in itself and equally so in its application, and never is the Saracenic dome concealed outside by a conical roof. The want of a crowning cornice to the long lines of the walls was to some extent supplied by a peculiarly bold crest ornament often filled in with rich scroll or other work. A variety of these adorns many of the mediæval palaces of Venice. The ornamentation was almost entirely conventional, as the strict rules of the Koran forbade the copying of any natural objects. That this rule was not always followed may be seen in the Alhambra; but it, nevertheless, was in general attended to, and wonderfully beautiful were the results of this absence of all copying. Intricate scrollwork, flat in appearance on the surface, but really in various planes and intertwining, formed the usual basis. And from the scrolls came a sort of leafwork certainly like nothing in nature, but most graceful and varied in its elegant curves. The whole is utterly conventional—as entirely the creation of the artist's mind as the most conventional work of a Gothic architect. The capitals of the columns were usually some adaptation of the classic. But in Spain, as specially seen in the Alhambra, they were of quite an original type, somewhat like that which we have described as being the germ of the Ionic, but with long leaves under the block, tied together with a band at the top of the shaft.

One of the ornaments peculiar to the Saracens, and constantly used by them, was the honey-comb by which they brought the square base, which they almost always used on plan, into the circular dome or niche-head. It was, in fact, the Saracenic pendentive. In its simplest form it occurs very early in the style, as, *e.g.*, at the Mosque of Tooloon at Cairo, and was composed of a series of small niches, the pointed head of each of which bent forward at the top and formed the springing point of two others. The repetition of a few rows of this produced a pendentive in which it is impossible to detect any harsh point of junction between the square base and the circular finish. Sometimes this honey-comb work was exceedingly intricate, and formed niche-heads, roofs, &c. Good examples of this occurs at the Zisa, Palermo, and at the Alhambra. The entrance doorways were often grandly composed in a very high square recess, but the Saracens were as careful as the Gothic architects not to dwarf the size of the interior of their buildings by making the actual openings large, and thus the recess was brought down in height by elaborate work in the upper part, and the actual doorway thus reduced to just the size required for use. The windows were, of necessity, small, in order to guard against the heat; they were fitted up with thick bars of marble or of plaster, in elaborate diaper patterns,

FIG. 50.—Capital and Springing of Arch, from the Hall of Abencerrages, Alhambra.

these being filled in with pot metal glass, brilliantly coloured. The ceilings, when not domed, were flat, showing the timbers, which, in the finest examples, were richly painted and gilt, the wood being first canvased over, and then covered with a fine thin stucco to receive the decoration. The pavements were of marble mosaic, in some cases lighted up in colour by enamelled earthenware tesseræ. The walls were often lined with still more elaborate mosaic, the outlines being in some cases marked out with mother-of-pearl. Add to this that the pulpits, doors, and other

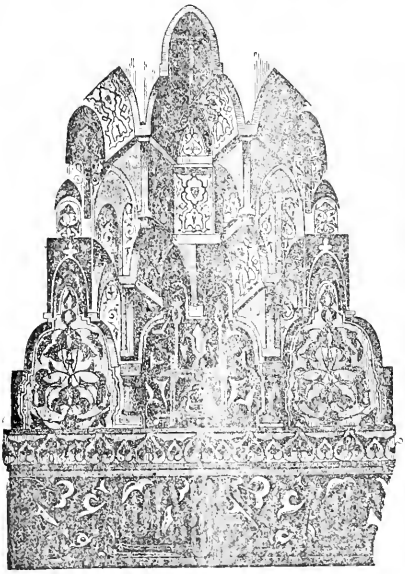

FIG. 51.—Pendentive, from the Court of the Lions, Alhambra.

woodwork were of the most exquisite workmanship, and the bronze hinges, &c., often chased in a manner scarcely to be paralleled in any other style, and we have a combination of outlines and details which could scarcely be surpassed in design or execution in buildings of a size comparatively so small. Admirable descriptions of Saracenic architecture in Spain have been given by the late Mr Owen Jones and M. Coste; of that in Egypt, also by M. Coste, and in India by Mr Fergusson. Of the houses in Egypt the best descriptions, probably, are those given in *The Modern Egyptians*, by Mr Lane, who has illustrated his work by numerous details of the carved wood and other work in which the Arabs excelled. Of the houses in Algiers, a peculiar class, an account is given by Professor Lewis in the *Transactions of the R. Institute of British Architects*, 1868-9.

It remains only to say that the present successors of the Saracens seem now to have lost nearly all claim to individuality in art, and to be unable even to copy or imitate the illuminated MSS., the mosaics, the carving in wood or in ivory, which lend so great a charm to the old work. What is now done is merely a copy, and a bad copy, of the work of their European neighbours.

CHINESE ARCHITECTURE.

The buildings of the Chinese are very inferior in character to those of India; in fact, Mr Fergusson goes so far as to say, "China possesses scarcely anything worthy of the name of architecture." Sir W. Chambers has described one of the Buddhist temples, that at Ho-nang, which is not unlike those of India in arrangement. There is an extensive court, with avenues of trees, leading to a

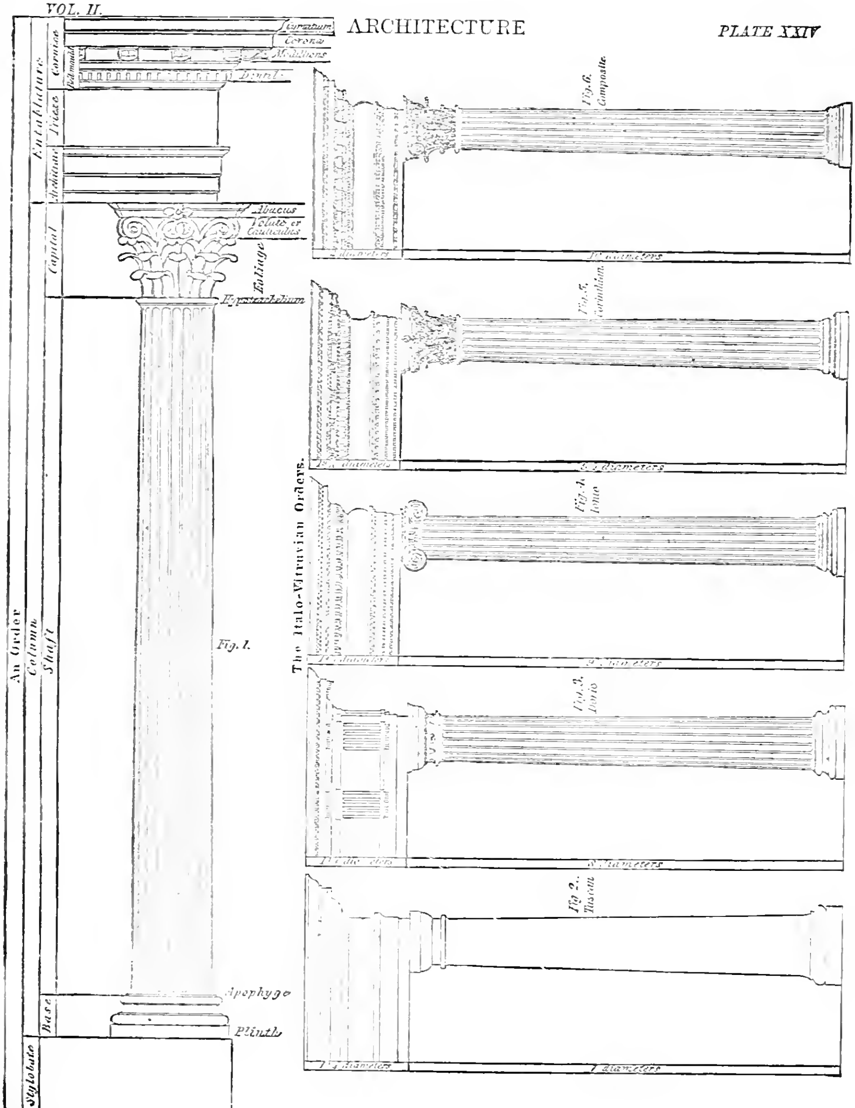
FIG. 52.—Temple of Confucius, Shanghai, China.

flight of steps and portico of four columns. In a second vestibule behind this are four colossal figures bearing various emblems. Beyond this is a very large second court, entirely surrounded by colonnades and small sleeping cells for the priests or *bonzes;* in other words, a huge cloister, much like the Indian viharas. In the same ranges are four pavilions filled with idols, and large rooms for refectories, behind which are the kitchen, courts, &c. At the extreme corners of the grand court are four other pavilions, the dwellings of the higher order of priests. At equal distances behind each other, down the centre of the court, are three larger pavilions, called *tings*, entered on each side by a flight of steps, and a fourth engaged in the cloister itself, and having a front portico and one flight of steps only. The first three are square, two stories in height, the lowest surrounded by fourteen columns, each face or front showing six. They have rude caps, composed of eight brackets, projecting various ways. Sir William Chambers says there are four species of *tings*,—three used for temples and the fourth for gardens; some having a gallery and fretted railing round the first floor on the outside, the upper story being set back. The roofs all have the peculiar hollow dip, which leads one to suppose their prototype was the tent, the sag of the cloth of which would suggest the form. They are frequently surmounted with a sort of cresting and finial, and each angle is turned up sharply, and ornamented with a dragon. Sometimes the columns have a frieze perforated in the form of frets; sometimes the same is also under the eaves of the upper roof. Examples are also given of smaller octagonal *tings*, intended to cover the large vessels in which the Chinese burn gilt paper to their idols.

Mr Simpson has given an interesting account of the temple of Heaven at Peking. It lies in an open space of about one mile square, surrounded by a triple enclosure. In this space were kept the animals destined for sacrifice. The temple proper consisted of several detached structures, the most sacred being to the south, and consisting of a

ARCHITECTURE

PLATE XXIV



raised platform approached by three terraces, and bearing simply an altar unscreened by any building and open to the sky. The northern structure was roofed but not enclosed.

FIG. 53.—Temple of Heaven, Peking.

Four pillars supported the main roof, which was 99 feet high, and lower roofs round the higher one were upheld by 24 columns of less height, all richly sculptured and gilt.

The accompanying illustrations (figs. 52 to 54) represent Chinese temples of different types.

The most striking buildings in China are, however, the tapering towers which they call *taas*, and our old writers pagodas. These are of brick covered with marble, or most generally with glazed tiles; and are built in stories, one over the other, from three, four, or five, to as many as nine in number. Each story is reduced in width, and has a gallery round it. The roofs are hollow or sagging, like those formerly described. They project a great deal, the corners being turned up sharply. On these light bells are suspended, which make a constant ringing when the wind blows. The roofs are covered with glazed tiles of various colours, and the summit ornamented with a species of spire and finial. The most celebrated of these was that known as the porcelain tower at Nanking. It had nine stories, and was about 200 feet high, exclusive of the iron spire. At each angle was a bell, making seventy-two in all; and there were eight chains hanging from the top of the finial to the angles of the spire, and carrying nine bells each, or seventy-two more. This celebrated building was destroyed by the Taepings in 1853. The *taa* is not a pagoda or temple, but a memorial of some event or of some great personage. At Peking is one used as an observatory, and at Nanganfoo one was erected simply to bring good luck.

Buildings called *Toov Tang*, or halls of ancestors, are found in all considerable towns. These much resemble temples, but instead of idols, memorial tablets are placed in the niches to record the transactions and deeds of the "worthies" or celebrated inhabitants of the neighbourhood.

The *Pai Loo*, or *Pai Fang*, is another common object in China. These are monumental memorials, though they have been mistaken for triumphal arches. Quatremère says, the Chinese annals reckon 3636 of these, erected in honour of literary men, philosophers, princes, generals, &c. The smaller are of wood, forming a sort of doorway. The larger have three openings side by side, and over these are several broad panelled fascias for inscriptions and carving, which is often very bold and in high relief, and over all is a projecting cornice carrying a tiled roof. Chambers has given one, the side gateways of which have semicircular arches, with festoons of drapery. The resemblance of these to the famous Sanchi tope is evident, as is also their

FIG. 54.—Temple of Agriculture, Peking.

being adaptations from wooden originals, for the stones are put together with mortices and other joints just as a wooden framework would be. The Chinese gateways are, however, very poor in comparison with those of India.

There is not much variety of design about the houses of the Chinese, as every one must be on a scale corresponding to the rank of the inhabitant. Le Comte mentions a case where a mandarin was obliged to pull down one that he had constructed of a somewhat better quality than those of the others. Chambers has given a plan of a house which he says is of very common design. It is about 260 feet from front to back, and about 65 feet wide. It is entered at the front by a passage nearly 20 feet wide, which goes nearly through the entire building. On each side of this, fronting the street, is a shop, with its back shop. It should be stated, that the divisions on the two sides of the central passage exactly correspond with each other. First we have two studies and two small bedrooms; then two saloons or reception rooms, about 24 feet by 18, looking into open courts or gardens, with fish ponds, fountains, flowers, &c., divided by walls; then two more saloons with bedrooms, and then the great dining-hall, which runs right across the house. This is about 60 feet by 30, and is carried on eight columns. Behind this is the kitchen and other offices. The first floor has two bedrooms, one on each side of a passage, for the shop-keeper; then on each side is a saloon and the bedrooms for the family. Between these last, and also carried on columns, is the hall where the family idol is worshipped. This overlooks the open gardens before mentioned. At the further end of these courts are two more saloons and bedrooms, and then a hall, said to be devoted to the use of strangers or visitors, which is over the ground floor dining-hall, and of the same size. Chambers tells us every house has a number of movable partitions kept ready, to be put up to subdivide the larger rooms.

The tombs are as singular as the rest of the Chinese edifices. The grandest of them, viz., those of the Ming dynasty, which ended in 1628, have been well described by Mr Simpson in the *Transactions of the R. I. B. A.*, 1873–4. One of these tombs is at Nanking, but the chief are about 40 miles north of Peking. The entry is by a grand Pai Loo of five gateways in white marble, and then through several other gateways to a singular dromos, nearly a mile long, of 32 colossal figures (ranged in pairs), some human, others of camels, griffins, elephants, &c. Such a dromos exists also at Shanghai. The tombs, thirteen in number, are ranged round the base of a hill and extend for several miles. Each consists of an earthen mound about half a mile in circuit, having, at its base, a crenellated retaining wall 20 feet high. The mound has no entrance, nor any indication of the exact place of burial. To the south of the tomb is a temple in an open court, about 1200 feet by 500. The plan is just the ordinary one of a palace, and the names, "The House of the living and the House of the dead," seem to show clearly that this resemblance was intended.

The Chinese method of construction is very peculiar. Their roofs are put up first, supported on wooden posts, which are removed as the permanent fabric is built. The walls of the grand edifices are of stone, but the ordinary material is brick, and the work is often executed with beautifully close joints. In palaces and temples the whole was often gorgeously coloured with glazed tiles, or the bricks themselves were coloured and glazed. A magnificent example of this is a temple near the summer palace at Peking, all of which is of bright majolica, except its marble base. As with all structures belonging to the emperor the colour was yellow, it being a capital offence for any other person to use that colour.

The Chinese never use square timber when they can get round trees of a suitable size, probably on account of the lightness, strength, and convenience of the bamboo. The roofs are of very peculiar construction, and all timbers are left visible. The windows are filled in with the lining of the oyster shell, which looks like talc, and is quite as transparent; and the main door is frequently a perfectly round aperture. The old buildings of the Chinese, like those of the Saracens, are fast going to decay, and the streets of even their grand capital, Peking, now exhibit immense ranges of ruined buildings.

Ancient American Architecture.

It was not long before the exhumation by Mr Layard, in Central Asia, of the wonderful remains of fine art entombed in earthen mounds, that Mr J. L. Stephens, when engaged on a mission from his Government—that of the United States of North America—to some of the mutable states

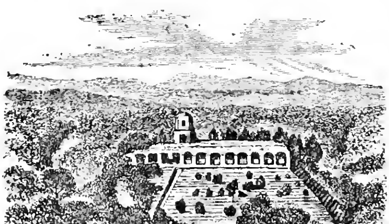


Fig. 55.—Ruins of *Teocalli* or Temple at Palenque.

of Central America, heard of and tracked out in the forests of Yucatan[1] the remains of a bygone time, exhibited in sculptural and architectural monuments of a coarse character, affording a strange counterpart to those which Mr Layard describes as having existed in and about the valleys of the Tigris and Euphrates. The remains of fifty or sixty cities have been discovered, the most interesting being those of Chololu, Palenque, Uxmal, Tescuco, and Mitla. The chief structures were evidently temples (*Teocallis*), raised high above the surrounding buildings on grand basements, square on plan, and rising by huge steps to the summit, so as to have the general outline of a low truncated pyramid. One at Palenque is 280 feet square at the base, and about 60 feet high to the platform, on which stands the temple, the latter being oblong on plan, measuring about 76 feet by 25. It was a low building, with a roof formed by stone gradini, so as to be, in fact, a continuation of the pyramid. Other structures, supposed to be palaces, are described by Mr Stephens, Mr Catherwood, Lord Kingsborough, &c., and copiously illustrated in their works. Many of them are very extensive, but of no great elevation. They are chiefly built on massive stone basements and surmounted by cornices, the friezes of which are adorned with evident imitations of logs of wood in upright rows. The greater part of the roofs were of wood, but among the objects represented in Mr Catherwood's *Views of Ancient Monuments in Central America, Chiapas, and Yucatan*, are several examples of vaults having the arch form, but not being arched vaults,—that is to say, of vaults presenting the appearance internally, or upon the soffit, of arches, but formed by the gathering over of horizontally-coursed masonry, with the inner and lower angles worked away—or cleaned off, as it is technically expressed—to the appearance on the inside which an arched vault would present.

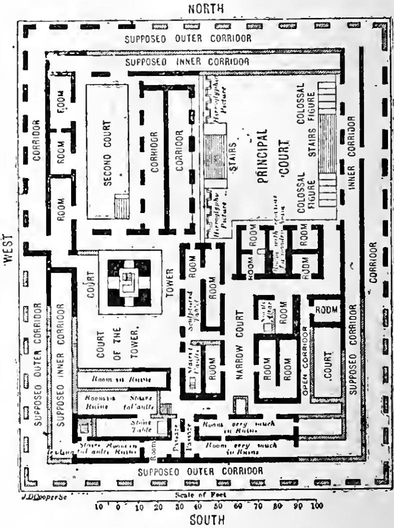

Fig. 56.—Plan of Temple at Palenque.

(See fig. 59.) The circumstance that the arch form presented in the American monuments is produced by the gathering over of horizontally-ranged masonry, and not by means of arch structure, would seem to show clearly that if the builders ever had intercourse with the Old World, it was before the properties of the arch were known and exemplified in it. These remains show an advance on the

[1] Lord Kingsborough's great work, *The Antiquities of Mexico*, contains in some of the later volumes, representations of monuments which would almost appear to be the same as some of those subsequently explored by Mr Stephens.

Pelasgic and Celtic monuments of the Old World, and

take the general character of the stoneworks of Egypt and India; but like those works, they exhibit the vaulted form by gathering over and not by arching.

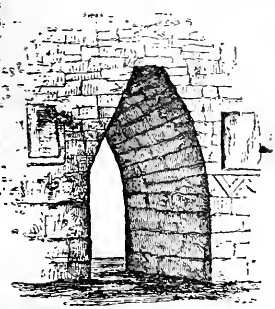

FIG 59.—Horizontally-Coursed Arch.

Mr Catherwood states that he and Mr Stephens concur in the opinion expressed by Mr Prescott, in his *History of the Conquest of Mexico*,—"that though the coincidences are sufficiently strong to authorise a belief that the civilisation of Anahuac (Ancient Mexico) was in some degree influenced by Eastern Asia, yet the discrepancies are so great as to carry back the communication to a very remote period, so remote that this foreign influence has been too feeble to interfere materially with the growth of what may be regarded, in its essential features, as a peculiar and indigenous civilisation;" and this opinion the monuments, as presented by Mr Catherwood, would seem fully to justify. But Mr Catherwood adds to this, as the ground, it would appear, for coinciding with Mr Prescott's opinion, that the results arrived at by Mr Stephens and himself "are briefly, that they (the American monuments) are not of immemorial antiquity, the work of unknown men; but that, as we now see them, they were occupied and probably erected by the Indian tribes in possession of the country at the time of the Spanish conquest, that they are the production of an indigenous school of art, adapted to the natural circumstances of the country, and to the civil and religious polity then prevailing; and that they present but very slight and accidental analogies with the works of any people or country in the Old World."

Less artistic, but more vast and massive, are the structures in Peru, which have been as yet imperfectly explored.

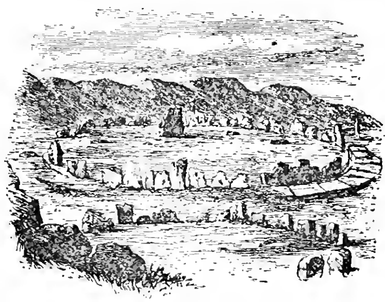

FIG. 60.—Stone Circles (*Intihuatanus*) at Sillustani. From Squier's *Peru*.

Referred by Mr Prescott to the reigns of the Incas, they are now considered to have been the works of a far earlier race,

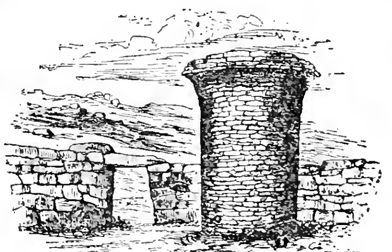

FIG. 61.—*Chulpa* or Burial Tower, Peru. From Squier.

of whom the Incas were the conquerors. The rudest of these early works are sepulchral, and much of the same kind as the cromlechs and stone-circles already referred to (p. 383). One circle at Sillustani is 90 feet diameter, another 150 feet, and they have a massive paved platform all round them outside, which is not found in similar remains in the Old World. The cromlechs are not covered merely by a flat stone, but are rudely domed over by overlapping stones.

A much more artistic class of tombs is built of stones in

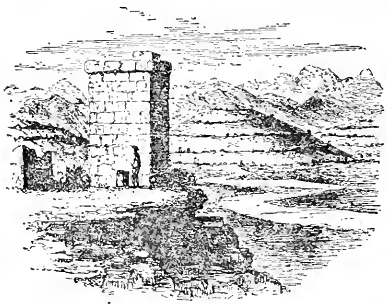

Fig. 62.—Square *Chulpa* or Burial Tower, Bolivia. From Squier.

the form of a tower, but *increasing* in width towards the top, and domed as above described. Most of them are round on plan, but some are square and two stories high, the upper being covered with overlapping stones cut to the arch shape. Many of these are of hard stone, beautifully fitted together, and the chambers are lined with a peculiar stucco still in good preservation.

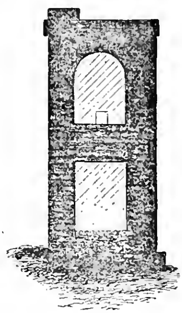

Fig. 63.—Section of Tower, fig. 62.

Some other sepulchral remains are on a much grander scale, being immense mounds held up by huge retaining walls. One of these mounds is 108 feet high, and 276 yards by 75 at the top. None seem to have been as yet explored. Of the fortresses one of the grandest examples is at Cuzco, 760 feet above the level of that city. It has three lines of fortifications in terraces 1800 feet long, the lower terrace having a retaining wall now 25 feet high, the second

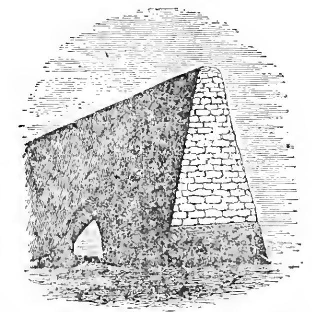

Fig. 64.—Cyclopean Wall at Chanchan. From Hutchinson's *Peru*.

30 feet behind the first) 18 feet, and the third (18 feet behind the second) 14 feet high. The walls are of cyclopean masonry, accurately fitted, one stone being 27 feet by 14 by 12, and many are 15 by 12 by 10 feet. The plan shows considerable skill, as the walls are not straight, but built with recesses and re-entering angles, evidently for giving the garrison command of the ground close to the walls. The most interesting remains in Peru are those called *Huacas;* but whether they were forts, or palaces, or tombs, is not as yet clearly ascertained. They are described as being enclosed by walls (in various examples 100 to 180 yards long, and 60 or 70 yards broad), and divided by cross walls, thus forming enclosures or chambers, many of which are still lined with stucco. In some of these are considerable remains of staircases, but the upper parts are destroyed. The chambers and enclosures are almost invariably filled with clay, which presents great difficulties in their examination. This filling in may, possibly, be accounted for by the construction of the walls, which are immensely thick (some at Chanchan are 15 feet), and usually of sun-dried bricks, either small (*adobes*), viz., about two-thirds the size of ours, or very large (*adobines*), some being 1 to 2 yards long.

Present Position of Architecture.

We have, in conclusion, a few remarks to make upon the present position of architecture. The increase of commerce and of wealth in the United Kingdom of late years, has thrown into the hands of the architect and engineer a vast amount of work, both for public and private edifices. Not only has there been an increase in the number of buildings, but the old parts of very many towns are being rebuilt on a larger and grander scale, and new, wide streets are being formed through their busiest and most densely peopled quarters. In London, in the great manufacturing towns of the north, in the universities, in the seaport towns, north and south, and in the pleasure-seeking cities on the sea-board on every coast, this process is going on at a rapid rate; and we look with interest and anxiety as to what are replacing the old buildings (many of them landmarks in our art) which have been destroyed, or what is to range beside those which are left. And besides these reconstructions, there are rising up, in every part of the country, railway stations, colossal hotels, baths and washhouses, working men's dwellings, and such other edifices as the Crystal and Alexandra Palaces, of a kind entirely unknown to the past generation. In addition to these we have the altogether new towns of Swindon, Wolverton, Crewe, Fleetwood, Barrow-in-Furness, Middlesborough, &c. These last afford, perhaps, the least encouraging view of modern work as contrasted with the old. Our old towns were usually picturesquely placed on the margin of a river for trade, or on a hill for defence; gradually increased round some nucleus of importance—a church or monastery or castle; and comprised the mansions of the rich as well as the shops of the trader and dwellings of the poor. But the modern town is all built at once, on some sudden call, on a site selected, perhaps, simply from its being at the junction of two railways. It shows only long straight streets of small dwellings for artisans, unbroken, except, perhaps, by a church, or an assembly-room, or more forcibly by the long, unpicturesque lines of railway sheds. Neither the architect nor the engineer has had much to do with this, and the result is about as wretchedly uninteresting a series of streets as it is possible to conceive. Horace Walpole's satirical description of London, "a gigantic mass of littleness," would apply well to them.

It has been better with the extension of the old towns. At first this gave us such long, bald lines of streets as Bath shows in stone, and Baker Street, &c., in London, in brick. These led by a natural result to a more ornate class, and we had the Regent's Park, and Regent Street, London, wherein a number of houses are grouped together into one mass, abounding with Roman columns and cornices, and receiving something of the massive appearance and lightness of stone from being covered with stucco, just as most of Palladio's buildings in Italy were. But whilst they were far better in general effect than the class which preceded them, the columns and their long unbroken lines of cornices often sadly interfered with the requirements of the dwellings, and in the new streets and terraces of our towns we see but few imitations of Roman porticoes and pediments, and the speculating builder mostly limits himself to putting a portico to the door, a few mouldings (in stucco) to the windows, and a slight cornice as a finish to the tops.

On the Continent the usual style of living—in flats—enables the builders to produce, with the same number of rooms, a more massive external effect than with us. One large entrance doorway suffices for the whole, and thus four or five separate houses (as they are in reality) have the effect of one large mansion. Still more is this the case when a courtyard, requiring a carriage entrance, occupies the centre of the building.

Of a far higher class than the private dwellings are many of the places of business recently erected in our great towns. In the new banks, exchanges, insurance offices, &c., many of our most noted architects have produced good results; and if we cannot congratulate ourselves upon much that is being done, we can, at least, say that the new work is an improvement upon the old. In no instance, perhaps, is the advance more to be noted than in the club-houses and the great warehouses for storing the lighter class of goods. A façade having long lines of windows, in many stories, each story of considerable height, and with only one main entrance doorway, affords the materials, of course, for forming a massive and pleasing effect much as that of the Continental houses above described. And the opportunity has certainly not been lost. Our plan, too, of letting each owner build to a considerable extent according to his own design, results in a more picturesque arrangement of our streets than those of a Continental town, which usually present lines of uninteresting houses, all of much the same design.

As a still further mark of progress we must mention the town-halls and other civic structures at Bradford, Halifax, Leeds, Liverpool, Manchester, Plymouth, Preston, &c., and the local museums and picture galleries, as at Cambridge, Edinburgh, Exeter, Leeds, Liverpool, Oxford, Salisbury, &c. Not only do these great civic buildings give importance by their magnitude to the towns, but they lead to other works in rivalry or imitation, just as a mediæval building of note did in olden times, and the goodness of their design is therefore a matter of prime importance. The museums are gradually helping to fill up a void most painfully felt by every stranger in our towns, and will help to preserve many local pieces of antiquity which would otherwise have been lost.

Of a higher class still are the colleges at Edinburgh, Glasgow, London, Manchester (Owens), &c., and many of the additions to those of the old universities. In these colleges the number of rooms of varying size, the entrance tower, and the internal quadrangles, allow of picturesque effects, but seldom present any one very grand mass. This has, however, been produced at University College, London, by the central portico (probably the finest in England), which rises high above the rest of the edifice.

In the civic buildings a bolder effect can be produced by their actual requirements, viz., a grand hall of large area and height, with spacious corridors and staircases, and a high clock tower, which seems to furnish the natural complement to such structures. If we have not rivalled Ypres, or Louvain, we have at least improved on the wretched civic buildings of the last century.

Larger and grander than any of the above works are the Houses of Parliament in London. However much of the detail may be open to criticism, it must be readily acknowledged that the architect had in his mind, and steadily carried out, the idea of combining the whole into one grand mass, in place of leaving it as a mere series of fronts, as in the Bank of England or Somerset House; and the variously designed steeples and towers culminating in the one grand tower at the royal entrance form the whole into one of the grandest buildings of the age.

Of a class unknown to the last generation are the railway stations, some of the largest edifices of the time, but usually almost hidden by another new class of buildings, viz., the colossal hotels. The stations themselves are in the main mere great vaults of glass on iron ribs, whose curved outlines are disfigured by the iron ties which the safety of a great extent of such roofing requires, and thus the only beauty, viz., the curved form, is to a large extent obscured. It is a fortunate circumstance that this form is the best adapted to the purpose, and when, as in many notable instances, the skill or good taste of the engineer has allowed of the ties being dispensed with, the vast size and lightness of the vault have a very impressive look. The hotels, which in most cases form the frontage of the stations in our country, are, for the most part, worthy of the striking positions which they occupy; but they are chiefly by living architects, and so beyond the scope of our criticism. No one, however, can study the way in which most of them are attached to the station buildings which they front without wishing most heartily that the engineer of the one and the architect of the other had worked somewhat more in harmony with each other.

Of an entirely novel design and construction was the Crystal Palace, admirably adapted, no doubt, for the purpose for which Paxton designed it, or for any other purpose for which a flood of light without impediment is required. But the manner in which the second, at Sydenham, has been altered is instructive. Where a grand orchestra was required the top was covered as a great sounding board, and when pictures or art works were to be exhibited the sides were closed,—the result showing plainly that the top lights are of the chief value, the side ones being little required except for the prospect through; and even for picture galleries a much smaller amount of light is required than in the Crystal Palace roof. Its curved form is, however, very pleasing, and the brilliancy of the light glass roof will ensure its being adopted in many buildings where a vivid light is required.

We have now passed hurriedly in review most of the forms of modern architecture, and we need scarcely add that it is developed in every conceivable style. If a church is to be built we may, indeed, pretty safely predict that it will be in one of the many pointed styles, but even then it may be English, French, or Italian. But of any other kind of edifice no one could safely predict the style. Probably it might be safe to assert that a theatre would not have (as Covent Garden in London had) a Grecian Doric portico, or an Egyptian pylon be made to do duty (as in Piccadilly, London) for a couple of shops. One might also be tolerably sure that a monument to a distinguished person would not be a granite column with a staircase up the middle, and a statue almost out of sight, with a lightning conductor through the head at top, as at the duke of York's column, London. But short of this, almost any prediction as to the style might come true; and as nearly every building of note throughout the world is brought to the eyes of the public by means of engravings or photographs, there seems little chance of its being otherwise.

In the United States the architects of the public build ings appear to be of much the same feeling as were English architects some years ago. The churches are often Gothic, but the other great edifices are in the main Italian, such as the capitols of Ohio, New York (Albany), and Washington. The last is a building of great size and picturesque outline, depending for its chief effect on the lavish use of porticoes and colonnades.

In Canada very much the same state of things exists as in the United States, the art in each being much the reflex of that in the old country.

The adoption of Greek, Roman, or Italian architectural details, little modified by climate and customs, is, in fact, to be noted in almost every country—any form of art peculiarly national being now abandoned in their favour; and if the houses in Paris were to be transported to Berlin or Cairo, they would simply agree with what has already been done in those cities. And if, further, the Bourse or the Pantheon at Paris, the Museum at Berlin, the Glyptothek at Munich, or the great church of St Isaac at St Petersburg, were to be severally changed to any of the other cities, it would be fairly in harmony with the modern works around it, though the nationality and language of the peoples in those cities are utterly distinct from each other. This abandonment of natural and peculiar styles is now producing another result quite foreign to anything known in art history before. From the earliest period known until the 17th century almost every nation had its own peculiar forms of art, and practised it (modified, perhaps, by the conditions of climate) in every part of the world which it colonised or conquered; and the result was the interesting remains of Roman art, clearly to be identified as such in Europe, Asia, and Africa; of Norman in France, England, Italy, and Sicily; and of Saracenic from Spain to India. This clear identification of a nation by its art works is as valuable to the historian as to the artist. But we can look for this no longer. We ourselves build Greek, Roman, or Italian palaces in our great towns of India, whilst close by, perhaps, is a church or cathedral in our English style of Gothic, and a college in the style of the Saracens, who themselves, centuries back, brought it with them as the art of foreign conquerors from Egypt or Persia. And the French in Algiers, to celebrate the triumph of their religion, erect a splendid church copied from the mosques of the people whom they have conquered, and whose religion they detest.

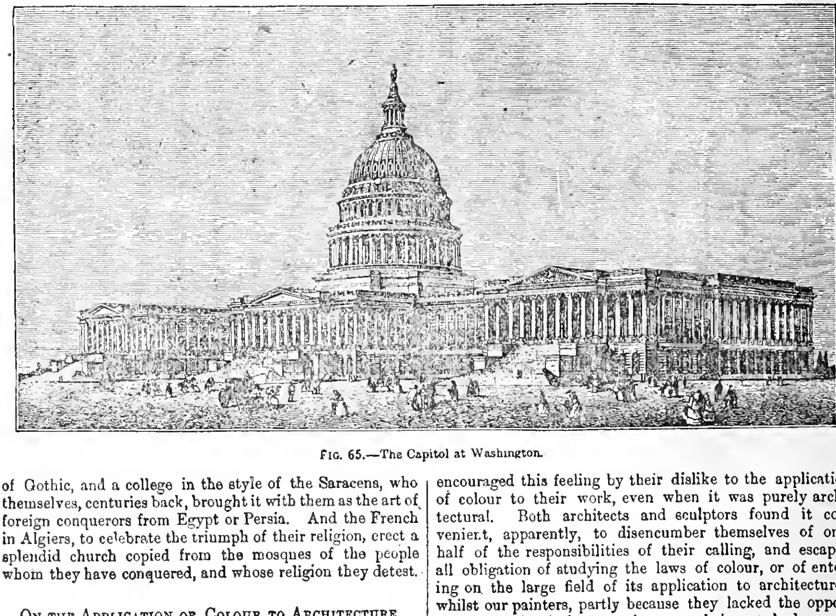

FIG. 65.—The Capitol at Washington.

ON THE APPLICATION OF COLOUR TO ARCHITECTURE.

On none of the subsidiary arts connected with architecture has there been in modern practice so little agreement with all ancient rules or customs as on this. It is only of late years that any one has conceded that the duty of architects is to give the best possible combination of form and colour, and that the completest form of architecture is that which affords examples of such a combination.

For the last three centuries architects have shown almost a contempt for colour, to such a degree, indeed, that the world till lately was taught to believe that purity of style and absence of colour always went together; and that it was only a vulgar and uneducated eye which saw the greatest evidence of good and matured taste in the harmonious application of colour and form. Our sculptors encouraged this feeling by their dislike to the application of colour to their work, even when it was purely architectural. Both architects and sculptors found it convenient, apparently, to disencumber themselves of one-half of the responsibilities of their calling, and escaped all obligation of studying the laws of colour, or of entering on the large field of its application to architecture; whilst our painters, partly because they lacked the opportunity, partly, it is true, because their art had ceased to be exercised for the public benefit in the old sense, had ceased to regard wall-painting as their legitimate work, and had so completely sunk into the habit of treating only small subjects in a small way, that it will take an age to develop in them the power of dealing properly with those large wall spaces which present them with the grandest opportunity of achieving real distinction. It it abundantly clear that those who argue against the application of colour to architecture, do so without the weight which the authority of their ancestors would have given them. Of late years much attention has been devoted to this point; there has been considerable discussion, and in the end, though there has been much difference of opinion as to the *extent* to which colour was applied by the Greeks and Romans, there has been none as to the fact that, at any rate, some introduction of colour was well-nigh invariable in their work. Mr Owen Jones's *Apology for the Colouring of the Greek Court* at the Crystal Palace contains, in a small compass, quite sufficient evidence to show how strong is the ground of those who maintain the necessity of colour in classic buildings; and equally valuable is the report, drawn up by the Committee of the Institute of British architects, on the colouring of the Elgin marbles, with Professor Faraday's analyses of portions of the coatings of marbles brought from several ancient buildings in Athens, upon all of which he makes it perfectly clear that colour was extensively and generally applied. Professor Semper of Berlin, in treating of the origin of architectural polychromy, proves that the Syrians, Persians, Egyptians, Chinese, Indians, Jews, Phœnicians, and Greeks all used colour in their architecture and sculpture, and we may safely conclude, therefore, that there is no country which has been in any way remarkable for its architectural monuments in which the necessity of the combination has been ignored or forgotten. This statement is sufficient on the subject so far as it affects all ancient schools of art.

If we turn to later times we shall discover in all the schools of mediæval artists a still greater and more pronounced adhesion to the same principle. It seems, indeed, almost superfluous to say that there are most abundant evidences of the fact that the architects of the Middle Ages were seldom satisfied until they had covered their walls with colour; in one place with that in which nature has been so lavish in marble and precious stones; in another with the artificial tints of tiles and bricks; in another with the bright stencilling of gay diapers over entire walls; or, lastly, in the teaching of Scripture story, or legend or history, by the aid of the greatest painters of the day.

If we look for an instant to Italy we shall see what a lesson these artists have left us there. There is, for instance, the Arena chapel at Padua, designed by Giotto, and then painted by him with his own hands in such fashion that, to the present day, this simple little room—some 20 feet by 40 in its dimensions—is one of the greatest pilgrimage places in Europe for all lovers of Christian art; and again, in that far grander work—the noble church so finely stationed on the steep slopes of the Apennines at Assisi—we see how Cimabue, Simone Memmi, Giotto, and many others, helped to cover with pictures, conceived in a really divine spirit, the walls which would otherwise, no doubt, have been resplendent with the less artistic, but still most effective labours of the patient stenciller. The same lesson is taught if we look at the Campo Santo of Pisa, and see how Andrea Orcagna, that great architect, painter, sculptor, and poet, and beside him a succession of artists, among whom we count Buffalmacco, Simone Memmi, Giotto, and Benozzo Gozzoli, helped each in their turn in this illumination of architecture; or at the church and refectory of Sta Croce, and the church and chapter-house of Sta Maria Novella, and the crypt of San Miniato, Florence; or at that masterpiece of decorative art—St Mark's at Venice—where precious marbles and mosaics rich in gold and bright colour almost dazzle the eye with their magnificence, but combine to make an interior in which none can fail to admit that the effect of the mere architecture of the building has been extraordinarily enhanced.

Nor was such practice as this peculiar to mediæval artists; for the earlier Renaissance men had the same feeling in some degree, and Benozzo Gozzoli has shown us in his exquisite paintings in the chapel of the Riccardi Palace at Florence, and Perugino and Raffaelle in the Stanze of the Vatican, how their work might be best adorned.

But it was not only in Italy—the land *par excellence* of colour—that men had a true appreciation of its value. It need hardly be told how St Louis, in the palmiest days of the French kingdom, covered the walls of the Sainte Chapelle of Paris with gold and colour and mosaic, and filled its windows with stained glass of the richest hues, so that to the present day it is an example of the most gorgeous colouring it is possible to conceive; or how, in England, when our monarchs wished to rival the zeal and enthusiasm of St Louis, they gave, in St Stephen's Chapel at Westminster, an example equally sumptuous and rich in colour: whilst at the same time, not only in our cathedrals, but in almost every parish church throughout our country, traces of more or less colouring are found to have existed over nearly the whole surface of the walls. Taking for granted, therefore, that every one will allow that it was, at any rate, the intention of all architects, as far as possible, to combine colour with form, it remains to be seen how this was accomplished.

There were two great and distinct orders of architectural colourists, the constructional and the decorative. The first were those who built their walls partially or altogether with coloured materials; the second those who so built them that colour might afterwards be added, and with an especial view to its introduction. It is of the works of the former of these two classes that it is right to speak first, because the way in which they did their work was, on the whole, a more thoroughly enduring and proper way than that of the other school. It was also more definitely the work of architects.

The works of the constructional school of architectural colourists must be subdivided into two classes:—1st, Those in which the coloured materials were part of the substance of the walls, and necessary for the stability of the whole fabric; and 2dly, Those in which the walls were covered with decoration, such as mosaic, or tiles, or thin veneers of marble, which had nothing whatever to do with their structural requirements.

The first class was that which was, on the whole, both the best and the most frequently adopted. The few examples which we see in this country, and, indeed, generally throughout the north of Europe, belong to it. The poverty of England in coloured stones or marbles will account sufficiently for the comparative rarity of the examples we can adduce. Among them are many of the Northamptonshire churches,—as Irchester, Strixton, and St Peter's, Northampton,—which are built with horizontal bands or courses of dark red and light stones used alternately; in other districts we find courses of stones and flint alternated, as in the church at Penton Mewsey, near Andover, and in a gateway at Rochester. In others flint and stone are used, but with inferior effect, in a regular chequer-work over the whole surface of the wall. In the church standing close to the north side of Rochester Cathedral, a course of chequer-work in flint and stone is introduced under one string-course, and two courses of flint separated by one of stone under another. The churches of Essex, Suffolk, and Norfolk abound in examples of tracery, and other devices formed by cutting out patterns in the stone, and filling them in with carefully-cut and faced flints of very dark colour, so as to produce a very elaborate system of decoration in two tints. In the cloisters of Westminster Abbey the groining is executed in chalk, with occasional lines of dark stone at regular intervals. Our red brick buildings are constantly diapered with patterns in black. The interiors of our churches, when not painted, were usually left with the natural colour of all the stone work—whether wrought or not—visible on the interior, an arrangement which, though rough and rugged in character, certainly gives a great amount of natural colour in a low key, but infinitely more agreeable to the eye than the cold expanse of plaster generally visible in new public buildings. Finally, throughout the 13th century the use of polished marble columns, of a colour much darker than that of the materials of the wall, is one of the most marked features in all the best English work, and cannot properly be omitted in any catalogue of modes of coloured construction. Every one of these arrangements is noticeable as having been introduced intentionally, and with a sole view to variety of colour. In France examples are much more numerous than in England, and the very interesting church at Vézelay is an early instance of the alternated use of dark and light stones in the interior as well as the exterior. Sta Maria in Capitolio, at Cologne, has some good remains of the same kind; and St Anne's Kloster, at Lübeck, is built with alternate courses of red brick and stone. It is in Italy, however, that we find the most plentiful store of examples of this kind of work, of which a few may be mentioned. The cathedral, baptistery, and the buildings generally in Pisa and Lucca are built, both inside and out, with white stone courses, with thin courses of black marble occurring at about every fourth course. This is a very delicate and effective mode of dividing the wall space. The baptistery and campanile of the cathedral at Pistoia, and the campanile of Siena, are built in almost equal courses of black and white. In Genoa we find the same equal division of the courses in the façades of the cathedral, and of the churches of San Matteo and San Stefano. At Bergamo the porch of Sta Maria Maggiore is executed in red, white, and grey marble. It is of three divisions in height, the highest stage being entirely of grey marble; the middle stage has all the moulded parts of red, and the arches and their spandrils of grey marble; the space at the back of the porch and over its main arch are built in equal courses of red and white marble; the groining is in black, red, and white marble, fitted to diamond-shaped panels, and all the shafts are of red marble. The whole design depends for effect almost entirely upon the arrangement and counter-changing of the three primary colours, the white becoming by age sufficiently yellow to take its place very well as one of them. Similar to this in the colours of its marbles is the 13th century front of the Broletto or town-hall at Como; but here the courses are very irregular in their height, and not arranged upon any symmetrical rule. The campanile of the cathedral at Florence is the last example of this class that need be mentioned, and it is the very finest of all; here the component colours are red marble of Perugia, green serpentine, and white marble (the two latter have the effect at a slight distance of being black and yellow), but these colours are further varied by the introduction of very elaborate patterns inlaid in delicate marble mosaic on almost every available space, whilst glass mosaic is introduced behind sculpture in the stages near the ground, in order to make the figures as distinct as possible. It is important to observe that, in this unsurpassed work, Giotto showed not only his sense of the value of colour, but equally his feeling for true architectural proportion. No building was ever more carefully designed in this way; and the result is so great a success in outline, in detail, and in colour, as to make it one of the most worthy of study of any work in Europe. Here it may be observed, that in the doorways of St Mark's, Venice, we have examples of exquisite beauty, of sculpture of foliage and figures in marble set off by a ground filled in entirely with mosaic, similar in idea to the way in which figures are set upon a mosaic ground in Giotto's work at Florence.

In the great church of San Petronio at Bologna, the flat space between the two stone moulded plinths is of red marble, and above the plinths the walls are all of red brick. This coloured plinth is very fine in its effect, and dignifies the whole building. The upper part of the Ducal Palace and the house called the Ca' d'Oro, at Venice, are examples of a coloured chequer-work over the whole surface of the wall. In the Ducal Palace this is arranged so as to form a regular diaper divided by lines of white and grey marble. The monument of Can Signorio, one of the Scaliger family, in the churchyard of Sta Maria l'Antica at Verona, is a good example of the successful application of coloured materials to works of delicate detail. It is a lofty erection, composed of a great canopied monument in the centre, with a number of smaller canopied niches rising out of it, or standing upon shafts around it. The base is all of red marble, the niches have red marble columns, white gables, and red pyramids above them. The central mass is mainly of a yellowish tint, with white marble niches and pinnacles of red marble, and, owing to the extent to which the colours are counterchanged, the effect is very good. The west doorway of Sta Anastasia, and the north doorway of San Fermo Maggiore, both at Verona, are beautiful examples of the simple alternation of white, red, and grey marbles in the jamb and arches; and in both these cases the extreme beauty of the effect appears to be owing to the delicacy and harmony of the tints of the marble employed, and to the absence of the very violent contrasts of colour which are sometimes seen.

There are other examples of buildings decorated with inlaid ornaments which belong to this class; such are some of the French churches, as, *e.g.*, those throughout the Puy de Dome, of which we may select as a typical example Nôtre Dame-du-Port, Clermont Ferrand. Here the lower part of the walls is of uniform colour, the windows have alternate voussoirs of light and dark stone, and the wall above them is entirely covered with a mosaic diaper; the walls are crowned by a heavy cornice supported on corbels, between each of which the space is filled in with a star in mosaic. Similar examples occur at S. Etienne, Nevers, in Poitou, on the banks of the Loire, and frequently in volcanic districts where dark and light materials, tufa and scoriæ, abound, and suggest the treatment which has been adopted. Some of the churches at Pisa are very beautifully and delicately enriched with inlaying. The little church of San Matteo has round all its arches inlaid chevrons, diamonds, or triangles, and a line of inlaying under the moulded eaves cornice of the aisle. The front of San Michele, also in Pisa, is covered with inlaid patterns filling in the spandrils, or following all the architectural lines of the arcading with which the whole upper portion is covered; similar inlaid patterns are to be seen between corbels under the tympanum of the south door of San Paolo, Pistoia. An inlaid pattern is carried along under the string-course below the aisle windows of the Cathedral of Lucca, and here, as in the other examples which have been given, the inlaid material is dark, on the white ground of the stone wall, and the object of its introduction was, no doubt, to give as much emphasis as possible to important features. In the case of the windows at Lucca the label is of dark marble, whilst the rest of the head of the window is white. In the church of San Domenico, Perugia, a window arch is built of grey stone, with occasional voussoirs of red, and on these, in order to make them as conspicuous as possible, small rosettes are carved. Another window in the same church has alternate voussoirs of red and white stone, and a red shaft for a monial. In the Palazzo Publico of Perugia the cornices and strings have ranges of corbels, the spaces between which are filled in with red marble to make the shadow deeper and more effective; in the windows, the shafts are of red marble; and in the doorway the tympanum is of red marble, with figures in white in front of it. The west front of Lucca Cathedral is inlaid in the most elaborate manner, the upper part with illustrations of field sports, and the lower part with geometrical patterns. Here, too, and in Giotto's campanile at Florence, the shafts themselves are inlaid in the same way as the rest of the work.

In the arcades outside the walls of San Fermo Maggiore, and in the windows of the little church opposite the cathedral, at Verona, great effect is produced by the ingenious combination of brick and stone; and throughout the north of Italy examples of this sort of arrangement of colour occur, and there is none more easy of imitation or reproduction with good effect at the present day and in our own country. In Sant' Antonio, at Padua, an arcade of brick and stone in the west front has all its spandrils filled in with red marble; and the case of the east end of the church at Murano will be remembered by all who have read Mr Ruskin's *Stones of Venice*. Here the substance of the walls is red brick for a few feet from the ground, and above that a rather coarse yellow brick; red brick is used in place of labels, &c., to define the arches; the shafts are of various marbles; and courses of marble, cut in triangles and alternately coloured and carved, are also introduced. The examples here given are enough to show, at any rate, the general prevalence of a love of colour in the Middle Ages throughout Europe.

It would be somewhat beyond the scope of the examination of such a subject from its architectural side to go at any length into the mode of decorative painting, which was almost universally adopted at the same time. In this application of colour all countries agree, and there is hardly room to doubt the beauty and expediency of the practice. The passage to the chapter-house at Salisbury, the early church of St Mary at Guildford, the chapels at the east end of Winchester Cathedral, are interesting English examples of early work. The Norfolk screens and roofs are still more interesting and beautiful works of the richest description, and so numerous were these that at one time no church seems to have been thought furnished which had none of this kind of decoration. These had every portion of their moulded surfaces adorned in the richest way with gold and colours, whilst their solid panels were covered with pictures of single figures or subjects. English roofs were decorated in the same fashion, and of these the finest examples are in Peterborough Cathedral and St Alban's Abbey. If we turn to the pages of illuminated manuscripts we shall find views of towns in which whole houses are decorated with masses of colour on the outside to distinguish them from their neighbours. And in rather later times, as we see in Florence, in Brescia, at Augsburg, at Meran, and often elsewhere, most brilliant effects were produced by painting subjects on the external walls of palaces and houses. But, generally speaking, beautiful as this sort of decoration was, it erred rather in ignoring to a considerable extent the architecture which it adorned,—unlike the earlier works, where the effort of the colourist was usually and rightly to make all the mouldings or members of the work decorated more distinct and intelligible than they can be in the absence of colour. Without coloured illustrations of an elaborate description it would be impossible to explain any or all the features of architectural polychrome. But enough has been said to show that the subject is one not only of interest to architects, but of importance to all who care for architecture, for it is hardly possible that works such as those which have here been shortly referred to should be passed over by the student or amateur of architecture as though they had no interest for us, and it may be confidently asserted that modern schools of architecture cannot with safety ignore so interesting a development of the art. (T. H. L.—G. E. S.)

List of Plates accompanying this Article.

Alphabetical Index.

GLOSSARY OF ARCHITECTURAL TERMS (ESPECIALLY CLASSICAL AND MEDIÆVAL).

Abaciscus, diminutive of Abacus, applied to the chequers or squares of a tessellated pavement.

Abacus, from the Gr. ἄβαξ, a tray, or flat board, Ital. *abaco*, Fr. *tailloir*, the upper part of the capital of a column, pier, &c. (See separate article, and Capital.)

Abated, a term for such work in mediæval masonry as is worked down or sunk.

Abbey (Fr. *abbaye*, Ital. *abbadia*, or contracted, *badia*, Ger. *Abtei*, *Kloster*), a term for the church and other buildings used by conventual bodies presided over by an abbot or abbess, in contradistinction to *cathedral*, which is presided over by a bishop, and *priory*, the head of which was a prior or prioress. (See separate article.)

Acroterium (Gr. ἀκρωτήριον, the summit or vertex), a statue or ornament of any kind placed on the apex of a pediment. The term is often restricted to the plinth, which forms the podium merely for the acroterium.

Aisle, sometimes written Isle, Yle, and Alley (Lat. and Ital. *ala*, Fr. *aile*, *bas-coté*, Ger. *Seitenschiff*, *Seitenchor*), in its primary sense the wing of a house, but generally used to describe the alleys or passages at the sides of the naves and choirs of churches. (See separate article.)

Alcove, a recess in a room usually screened off by pillars, balustrade, or drapery.

Alien-Houses, religious houses in England belonging to foreign ecclesiastics, or under their control. They generally were built where property had been left by the donors to foreign orders to pray for their souls. They were frequently regular *priories*, but sometimes only *cells*, and even *granges*, with small chapels attached. Some, particularly in cities, seem to have been a sort of mission-houses. There were more than 100 in England. Many alien-houses were suppressed by Henry V., and the rest by Henry VIII.

Alley, also called Ambulatory (Lat *deambulatorium*), the covered passages round a cloister. (See also Alure.)

Almery, also Aumery, Aumbrie, and Ambry (Fr. *armoire*, Ital. *armario*), a recess in the wall of a church, sometimes square-headed, and sometimes arched over, and closed with a door like a cupboard—used to contain the chalices, basins, cruets, &c., for the use of the priest; many of them have stone shelves. They are sometimes near the piscina, but more often on the opposite side. The word also seems in mediæval times to be used commonly for any closed cupboard, and even bookcase.

Almonry (Lat. *eleemosinarium*, Fr. *aumonerie*, Ger. *Almosenhaus*), the place or chamber where alms were distributed to the poor in churches, or other ecclesiastical buildings. At Bishopstone Church, Wiltshire, it is a sort of covered porch attached to the south transept, but not communicating with the interior of the church. At Worcester Cathedral the alms are said to have been distributed on stone tables, on each side, within the great porch. In large monastic establishments, as at Westminster, it seems to have been a separate building of some importance, either joining the gatehouse or near it, that the establishment might be disturbed as little as possible.

Almshouses, small buildings for the residence of the aged poor, generally endowed with some yearly stipend. The greater portion were built after the Reformation. Two interesting early examples are—that at St Cross, near Winchester, and that near the Preaching Cross of the Black Friars at Hereford.

Altar, anciently written Auter, or Awter (Lat. and Ital. *altare*, Fr. *autel*), the elevated table devoted to the celebration of the Eucharist. (See separate article.)

Alure (Lat. *alura*—*allorium*, probably from *alatorium*), an alley, passage, the water way or flat gutter behind a parapet, the galleries of a clerestory, sometimes even the aisle itself of a church. The term is sometimes written *valure*, or *valoring*.

Amphiprostyle (Gr. ἀμφί, around or about, and *prostyle*, *q.v.*) A temple with a portico at each end is said to be amphiprostylar.

Angel-Lights, the outer upper lights in a perpendicular window, next to the springing; probably a corruption of the word angle-lights, as they are nearly triangular.

Annulet (Lat. *annulus*, a ring), a term applied to the small fillets or bands which encircle the lower part of the Doric capital immediately above the neck or trachelium.

Antæ (probably from the Gr. ἀντίος, or some other derivative of the preposition ἀντί, opposite to), the pier-formed ends of the walls of a building, as in the portico of a Greek temple. A portico is said to be *in antis* when columns stand between antæ, as in the temple of Theseus, supposing the peristyle or surrounding columns removed.

Ante-Chapel, a small chapel forming the entrance to another. There are examples at the Cathedral and at Merton College, Oxford, and at King's College, Cambridge, besides several others. The ante-chapel to the Lady chapel in cathedrals is generally called the Presbytery.

Ante-Choir, the part under the rood loft, between the doors of the choir and the outer entrance of the screen, forming a sort of lobby. It is also called the Fore-Choir.

Antefixæ (Lat. *ante*, before, and *fixus*, fixed), upright blocks with an ornamented face placed at regular intervals on a cornice. Antefixæ were originally adapted to close and hide the lower ends of the joints of the covering tiles on the roof of a temple.

Apophyge (Gr. ἀποφυγή, a flying off), the lowest part of the shaft of an Ionic or Corinthian column, or the highest member of its base if the column be considered as a whole. The apophyge is the inverted cavetto or concave sweep, on the upper edge of which the diminishing shaft rests.

Apse (Gr. ἁψίς, Lat. *absis*, *tribuna*, *concha*, Fr *abside*, *rond-point*, Ital. *apside*, *tribuna*, Ger. *Ablauf*), the semicircular or polygonal termination to the chancel of a church. (See separate article.)

Apteral (Gr. *a* priv., and πτερόν, a wing), a temple without columns on the flanks or sides.

Aræostyle (Gr. ἀραιός, rare or weak, and στῦλος, a column), a wide intercolumniation. (See Eustyle.) The space assigned to this term by Vitruvius is uncertain; the moderns assign to it four diameters.

Aræosystyle (compounded of *aræostyle* and *systyle*, *q.v.*) expresses the arrangement attendant on coupled columns, as in the western front of St Paul's Cathedral.

Arcade (Fr. *arcade*, *arcature*, Ital. *arcata*, Ger. *Bogengang*), a range of arches, supported either on columns or on piers, and detached or attached to the wall. (See separate article.)

Architrave (Gr. ἀρχή, chief, and Lat. *trabs*, a beam), the chief, beam—that part of the entablature which rests immediately on the heads of the columns and is surmounted by the frieze; it is also called the epistylium or epistyle. The moulded enrichment on the sides and head of a door or window is called an architrave.

ARCHIVOLT, a contraction of the Italian *architrave voltato*, is applied to the architrave moulding on the face of an arch, and following its contour.

ARMATURE, the French term for the iron stays by which the lead lights are secured in windows. (See STANCHIONS and SADDLE BARS.)

ARRIS, the sharp edge or angle in which two sides or surfaces meet.

ASHLAR, also written Ashler, Ashelere, &c., (probably from the Lat. *assella*), squared stones, generally applied to those used for facing walls. In a contract of date 1398 we read—"Murus erit exterius de pure lapide vocato *achilar*, plane incisso, interius vero de lapide fracto vocato *roghwall*." "Clene hewen" ashler often occurs in mediæval documents; this no doubt means tooled or finely scappled, in contradistinction to rough-axed, faces.

ASHLER PIECES, upright pieces of wood going from the common rafters so as to cut off the lower angle of the roof in the attic story.

ASTRAGAL (Gr. ἀστράγαλος, a bone of the ancle), a convex moulding. This term is generally applied to small mouldings, torus to large ones of the same form. (See TORUS.)

ATTIC, a low story above an entablature, or above a cornice which limits the height of the main part of an elevation. Although the term is evidently derived from Ἀττικός, we find nothing exactly answering to it in Greek architecture; but it is very common in both Roman and Italian practice. What are otherwise called tholobates in St Peter's and St Paul's Cathedrals are frequently termed attics.

BACK-CHOIR, a place behind the altar in the principal choir, in which there is, or was, a small altar standing back to back with the former.

BAHUT, the French term for a wall of plain masonry on which there is some superstructure.

BAILEY, said to be a corruption of *Ballium* by some, and derived by others from the French "baille," a corruption of "bataille," because there the soldiers were drilled in battle array; the open space between the inner and outer lines of a fortification. Sometimes there were more than one, as the Inner and Outer Bailey; we have the Old Bailey at London and at York, and the Upper and Nether Baileys at Colchester.

BALDAQUIN, BALDACCHINO. See CIBORIUM.

BALL-FLOWER, an ornament in the form of a ball inserted in the cup of a flower, which came into use in the latter part of the 13th, and was in great vogue in the early part of the 14th century. It is generally placed in rows at equal distances in the hollow of a moulding, frequently by the sides of mullions. The earliest known is said to be in the west part of Salisbury, where it is mixed with the tooth ornament. It seems to have been used more and more frequently, till at Gloucester Cathedral, in the south side, it is in profusion.

BALUSTER, a small column or pier supporting the coping in a pierced parapet: the parapet itself when pierced is hence called a *Balustrade*.

BALUSTER SHAFT, the shaft dividing a window in Saxon architecture. At St Alban's are some of these shafts, evidently out of the old Saxon church, which have been fixed up with Norman capitals.

BAND, a sort of flat frieze or fascia running horizontally round a tower or other parts of a building, particularly the base tables in perpendicular work, commonly used with the long shafts characteristic of the 13th century. It generally has a bold, projecting moulding above and below, and is carved sometimes with foliages, but in general with cusped circles, or quatrefoils, in which frequently are shields of arms.

BAND OF A COLUMN (Fr. *bague*), a series of annulets and hollows going round the middle of the shafts of columns, and sometimes of the entire pier. They are often beautifully carved with foliages, &c., as at Amiens. In several cathedrals there are rings of bronze apparently covering the junction of the frusta of the columns. At Worcester and Westminster they appear to have been gilt; they are there more properly called Shaft Rings.

BAPTISTERY, a separate building to contain the font, for the rite of baptism. They are frequent on the Continent—that at Rome near St John Lateran, and those at Florence, Pisa, Pavia, &c., are all well-known examples. The only examples in England are at Cranbrook and Canterbury—the latter, however, is supposed to have been originally part of the treasury.

BARBICAN, an outwork for the defence of a gate or drawbridge; also a sort of pent-house or construction of timber to shelter warders or sentries from arrows or other missiles.

BARGE BOARD. See VERGE BOARD.

BARTIZAN, supposed to be derived from the Ger. *Bartizene* (Fr. *échauguette*), a small turret, corbelled out at the angle of a wall or tower to protect a warder and enable him to see around him. They generally are furnished with oylets or arrow-slits.

BASE (Gr. Βάσις, Lat. *spira*, *basis*, Fr. and Ital. *base*, Ger. *Fuss*), that part of a column on which the shaft stands. The only base used by the Egyptians was a mere square plinth. The Assyrians evidently understood the value of a base as an architectural accessory, and some bases shown on the bas-reliefs are strongly moulded. But all actually remaining are like the one recently placed in the British Museum, which consists merely of a large torus. The Persian bases were finely moulded, elegant in outline, and more richly ornamented than in any other style. The chief mouldings are a torus, and a large reversed cyma. In pure Greek work a base is never used in the Doric, but always in the Ionic and Corinthian. The plainer sort is that well known as the Attic, consisting mainly of a hollow between two tori; but the tori are, in other instances, deeply channelled, so as to have a very complicated appearance. The Romans had bases to all their orders, the more usual form being like the Attic. The Romanesque and Norman bases were evidently copies, for the most part, from classic forms; but were often adorned with leaves at the angles of the square plinths, thereby leading them into the round in a very pleasing way. This was done still more elegantly in the Early English style, whose most characteristic base was much like the Attic, but with the hollow prolonged upwards in a deep water-holding section. The Perpendicular were mostly very high, formed with two or more plinths and bold mouldings, chiefly reversed ogees.

BASE COURT (Fr. *basse cour*, *i.e.*, the lower court), the first open space within the gates of a castle. It was used for exercising cavalry, and keeping live stock during a siege. (See ENCEINTE.)

BASE OF A WALL, or GROUND TABLE, mouldings round a building just above ground; they mostly consist of similar members to those above described (BASE), and run round the buttresses. The flat band between the plinth and upper mouldings is frequently panelled and carved with shields, as in Henry VII. Chapel at Westminster.

BASEMENT. A basement story is a story placed wholly or partly below the level of the ground on the outside of and about the building. Basement, applied specially, as architects apply it, means the compartment in the elevation of a building upon which any columnar pilastered or arcaded ordinance may rest; as in the Strand front of Somerset House, of which the basement begins at the level of the floor of the vestibule, being about that of the street pavement, and extends upwards to half the height of the adjoining building east and west.

BASILICA (Gr. βασιλική, *i.e.*, the royal house), a term given by the Greeks and Romans to the public buildings devoted to judicial purposes. (See separate article.)

BATEMENT LIGHTS, the lights in the upper part of a perpendicular window, abated, or only half the width of those below.

BATTER (Fr. *battre*, to beat). Building over in projecting courses like inverted steps is termed battering, gathering, or corbelling over. The term is often applied to the converse operation of throwing back, as in a revêtement or retaining wall.

BATTLEMENT (Fr. *bretesse*, Ital. *merlo*, Ger. *Zinne*), a parapet with a series of notches in it, from which arrows may be shot, or other instruments of defence hurled on besiegers. The raised portions are called *merlons*, and the notches *embrasures*, or *crenelles*. The former were intended to cover the soldier while discharging his weapon through the latter. Their use is of great antiquity; they are found in the sculptures of Nineveh, in the tombs of Egypt, and on the famous François vase, where there is a delineation of the siege of Troy. In ecclesiastical architecture the early battlements have small shallow embrasures at some distance apart. In the Decorated period they are closer together, and deeper, and the mouldings on the top of the merlon and bottom of the embrasure are richer. During this period, and the earlier part of the Perpendicular, the sides or cheeks of the embrasures are perfectly square and plain. In later times the mouldings were continued round the sides, as well as at top and bottom, mitring at the angles, as over the doorway of Magdalene College, Oxford. The battlements of the Decorated and later periods are often richly ornamented by panelling, as in the last example. In castellated work the merlons are often pierced by narrow arrow-slits. (See OYLET.) In South Italy some battlements are found strongly resembling those of old Rome and Pompeii; in foreign ecclesiastical architecture the parapets are very rarely embattled.

BAY (Fr. *travée*, Ital. *compartimento*, Ger. *Abtheilung*), any division or compartment of an arcade, roof, &c. Thus each space from pillar to pillar, in a cathedral, is called a bay, or severey.

BAY WINDOW, any window projecting outwards from the wall of a building, either square or polygonal on plan, and commencing from the ground. If they are carried on projecting corbels, they are called Oriel windows. Their use seems to have been confined to the later periods. In the Tudor and Elizabethan styles they are often semicircular on plan, in which case some think it more correct to call them Bow Windows. For those in mediæval halls, see DAIS, HALL.

Bead, a small cylindrical moulding of frequent use.

Bed-Mould, the congeries of mouldings which is under the projecting part of almost every cornice, of which, indeed, it is a part.

Belfry (Fr. *clocher*—if applied to a church, *beffroi*—if to the tower of a hotel de ville; Ital. *campanile*, Ger. *Glockenthurm*), properly speaking, a detached tower or campanile containing bells, as at Evesham, but more generally applied to the ringing room or loft of the tower of a church. (See Tower.)

Bell of a Capital. In Early English and Decorated work, immediately above the necking is a deep, hollow curve; this is called the bell of a capital. It is often enriched with foliages.

Bell-Cot, Bell-Gable, or **Bell-Turret.** The place where one or more bells are hung in chapels, or small churches which have no towers. Bell-cots are sometimes double, as at Northborough and Coxwell; a very common form in France and Switzerland admits of three bells. In these countries also they are frequently of wood, and attached to the ridge. Those which stand on the gable, dividing the nave from the chancel, are generally called Sanctus Bells. A very curious, and it is believed unique, example at Cleves Abbey juts out from the wall. In later times bell turrets were much ornamented these are often called Flèches.

Bema (Gr. βῆμα, Lat. *tribunal*), the semicircular recess or hexedra, in the basilica, where the judges sat, and where in after times the altar was placed. It generally is roofed with a half dome or *concha*. The seats, θρόνοι, of the priests were against the wall, looking into the body of the church, that of the bishop being in the centre. The bema is generally ascended by steps, and railed off by Cancelli.

Bench Table, the stone seat which runs round the walls of large churches, and sometimes round the piers; it very generally is placed in the porches.

Bezantée, a name given to an ornamented moulding much used in the Norman period, resembling bezants, coins struck in Byzantium.

Billet (Fr. *billette*), a species of ornamented moulding much used in Norman, and sometimes in Early English work, like short pieces of stick cut off and arranged alternately.

Blocking-Course, a deep but slightly projecting course in an elevation, to act as cornice to an arcade, or to separate a basement from a superior story. (See String-Course.)

Boss (Fr. *clef de voûte*, Ital. *bozza*, Ger. *Buckel*), an ornament, generally carved, forming the key-stone at the intersection of the ribs of a groined vault. Early Norman vaults have no bosses. The carving is generally foliage, and resembles that of the period in capitals, &c. Sometimes they have human heads, as at Nôtre Dame at Paris, and sometimes grotesque figures. In later vaulting there are bosses at every intersection.

Bowtell (supposed to be akin to *Bottle*), the mediæval term for a round moulding or torus. When it follows a curve, as round a bench end, it is called a Roving Bowtell, *q.v.*

Brace Mould, two ressaunts or ogees united together like a brace in printing, sometimes with a small bead between them.

Bracket (Fr. *corbeau*, *cul-de-lampe*, Ital. *mensola*, Ger. *Kragstein*), a projecting ornament carrying a cornice. Those which support vaulting shafts or cross springers of a roof are more generally called Corbels.

Brattishing or **Brandishing**, is no doubt derived from the French *breteche*, a sort of crest ridge on a parapet, or species of embattlement. The term, however, is generally employed to describe the ranges of flowers which form the crests of so many parapets in the Tudor period.

Broach (from *broche*, a spit), now used to designate a particular form of spire, the sides of which, with the angles of the tower, finish with a sort of haunching. (See Spire.)

Buttress, anciently written Botrasse, or Boterasse (Ital. *puntello*, Fr. *contrefort*, Ger. *Strebepfeiler*), masonry projecting from a wall, and intended to strengthen the same against the thrust of a roof or vault. Buttresses are no doubt derived from the classic pilasters which serve to strengthen walls where there is a pressure of a girder or roof timber. In very early work they have little projection, and in fact are "strip-pilasters." In Norman work they are wider, with very little projection, and generally stop under a cornice or corbel table. Early English buttresses project considerably, sometimes with deep sloping weatherings in several stages, and sometimes with gabled heads, as at Beverley. Sometimes they are chamfered, and sometimes the angles have jamb shafts, as in the last example. At Wells and Salisbury they are richly ornamented with canopies and statues. In the Decorated period they became richly panelled in stages, and often finish with niches and statues and elegantly carved and crocketted gablets, as at York. In the Perpendicular period the weatherings became waved, and they frequently terminate with niches and pinnacles.

Buttress, Flying (Fr. *arc-boutant*, Ital. *puntello arcuato*, Ger. *Strebebogen*), a detached buttress or pier of masonry at some distance from a wall, and connected therewith by an arch or portion of an arch, so as to discharge the thrust of a roof or vault on some strong point.

Buttress Shafts, slender columns at the angle of buttresses, chiefly used in the Early English period.

Cabling. The flutes of columns are said to be cabled when they are partly occupied by solid convex masses, or appear to be refilled with cylinders after they had been formed.

Caisson. See Cassoon.

Campanile, a name given in Italy to the bell tower of a town hall or church. In that country this is almost always detached from the latter. (See Belfry.)

Canopy, the upper part or cover of a niche, or the projecting ornament over an altar or seat or tomb. The word is supposed to be derived from *conopæum*, the gauze covering over a bed to keep off the gnats (κώνωψ), a mosquito curtain. Early English canopies are generally simple, with trefoiled or cinquefoiled heads; but in the later styles they are very rich, and divided into compartments with pendants, knots, pinnacles, &c. The triangular arrangement over an Early English and Decorated doorway is often called a canopy. The triangular canopies in the north of Italy are peculiar. Those in England are generally part of the arrangement of the arch mouldings of the door, and form, as it were, the hood-moulds to them as at York. The former are above and independent of the door mouldings, and frequently support an arch with a tympanum, above which is a triangular canopy, as in the Duomo at Florence. Sometimes the canopy and arch project from the wall, and are carried on small jamb shafts, as at San Pietro Martire at Verona. An extremely curious canopy, being a sort of horse-shoe arch, surmounting and breaking into a circular arch, from Tournay is given. Similar canopies are often over windows, as at York Minster over the great west window, and lower tiers in the towers. These are triangular, while the upper windows in the towers have ogee canopies.

Cant. When the corner of a square is cut off octagonally, it is said to be *canted*. Thus a bay window with octagonal corners is called a canted bay.

Capital (Gr. κεφάλαιον, Lat. *capitulum*, Ital. *capitello*, Sp. *chapitel*, Ger. *Knauff*, *Kapital*, Fr. *chapiteau*), the upper part of a column, pilaster, pier, &c. Capitals have been used in every style down to the present time. That mostly used by the Egyptians was bell-shaped, with or without ornaments. The Persians used the double-headed bell, forming a kind of bracket capital. The Assyrians apparently made use of the Ionic and Corinthian, which were developed by the Greeks, Romans, and Italians, into their present well-known forms. The Doric was apparently an invention or adaptation by the Greeks, and was altered by the Romans and Italians. But in all these examples, both ancient and modern, the capitals of an order are all of the same form throughout the same building, so that if one be seen the form of all the others is known. The Romanesque architects altered all this, and in the carving of their capitals often introduced such figures and emblems as helped to tell the story of their building. Another form was introduced by them in the curtain capital, rude at first, but afterwards highly decorated. It evidently took its origin from the cutting off of the lower angles of a square block, and then rounding them off. The process may be distinctly seen, in its several stages, in Mayence Cathedral. But this form of capital was more fully developed by the Normans, with whom it became a marked feature. In the Early English capitals a peculiar flower of three or more lobes was used, spreading from the necking upwards in most graceful forms. In Decorated and Perpendicular this was abandoned in favour of more realistic forms of crumpled leaves, enclosing the bell like a wreath. In each style bold abacus mouldings were always used, whether with or without foliage.

Carrels (Lat. *carola*), small chapels or oratories enclosed by screens; also sometimes the rails of the screens themselves; and sometimes the separate seats or pews for monks near the windows. It was at one time supposed that the scrolls on which inscriptions of texts, &c., are formed were called carrels, but this seems a mistake.

Caryatides, human female figures used as piers, columns, or supports. *Caryatic* is applied to the human figure generally when used in the manner of Caryatides.

Casement, a deep hollow moulding, sometimes filled with foliage, and then called a Vignette; also the frame which holds the lead lights of a quarrel-glazed window.

Cassoon, or **Caisson**, a deep panel or coffer in a soffit or ceiling. This term is sometimes written in the French form, *caisson*, sometimes derived directly from the Italian *cassone*, the augmentative of *cassa*, a chest or coffer.

Cathedral (Ital. *duomo*, *cattedrale*, Fr. *cathédrale*, Ger. *Domkirche*), the principal church where the bishop has his seat (*cathedra*) as diocesan. (See separate article.)

Cathetus (Gr. κάθετος, a perpendicular line). The eye of the volute is so termed because its position is determined, in an Ionic or voluted capital, by a line let down from the point in which the volute generates.

Cauliculus (Lat. a stalk or stem), the inner scroll of the Corinthian capital. It is not uncommon, however, to apply this term to the larger scrolls or volutes also.

Cavetto (Ital. *cavare*, to dig out), a moulding whose form is a simple concave, impending.

Ceiling (Ital. *soffito, soppalcho*, Fr. *plafond, lambris*, Ger. *Stubendecke*), that covering of a room which hides the joists of the floor above, or the rafters of the roof. Most churches have either open roofs, or are groined in stone. At Peterborough and St Albans there are very old flat ceilings of boards curiously painted. In later times the boarded ceilings, and, in fact, some of those of plaster, have moulded ribs, locked with bosses at the intersection, and are sometimes elaborately carved. In the cloisters at Lincoln, the nave and choir at York, the side aisles of the choir at Winchester, the church at Warmington, and several other places, there are ceilings formed of oak ribs, filled in at the spandrils with narrow thin pieces of board, in exact imitation of stone groining. In the Elizabethan and subsequent periods, the ceilings are enriched with most elaborate ornaments in stucco. (See Groined Vaulting.)

Cells, small monastic houses, generally in the country, belonging to large conventual buildings, and intended for change of air for the monks, as well as places to reside in to look after the lands, vassals, &c. Thus Tynemouth was a cell to St Albans; Ashwell, Herts, to Westminster Abbey. (See Grange.) Also the small sleeping apartments of the monks; also a small apartment used by the anchorite or hermit.

Chamfer, Champfer, or Chaumfer. When the edge or arris of any work is cut off at an angle of 45° in a small degree, it is said to be chamfered; if to a large scale, it is said to be a canted corner. (See Cant.) The chamfer is much used in mediæval work, and is sometimes plain, sometimes hollowed out, and sometimes moulded.

Chamfer Stop. Chamfers sometimes simply run into the arris by a plane face; more commonly they are first stopped by some ornament, as by a head; they are sometimes terminated by trefoils, or cinquefoils, double or single, and in general form very pleasing features in mediæval architecture.

Chancel, a place separated from the rest of a church by a screen (*cancellus*). The word is now generally used to signify the choir of a small church.

Chantry (Lat. *cantuaria*, Fr. *chantrerie*, Ger. *Kantorei*), a small chapel generally built out from a church. They generally contain a founder's tomb, and are often endowed places where masses might be said for his soul. The officiator, or mass priest, being often unconnected with the parochial clergy, the chantry has generally an entrance from the outside.

Chapel (Lat. and Ital. *capella*, Fr. *chapelle*, Ger *Kapelle*), a small, detached building used as a substitute for a church in a large parish; an apartment in any large building, a palace, a nobleman's house, an hospital or prison, used for public worship; or an attached building running out of and forming part of a large church, generally dedicated to different saints, each having its own altar, piscina, &c., and screened off from the body of the building.

Chapiter, the old English name for a Capital.

Chapter House (Lat. *capitolium*, Ital. *capitolo*, Fr. *chapitre*, Ger. *Kapitelhaus*), the chamber in which the chapter or heads of the monastic bodies assembled to transact business. They are of various forms; some are oblong apartments, as Canterbury, Exeter, Chester, Gloucester, &c.; some octagonal, as Salisbury, Westminster, Wells, Lincoln, York, &c. That at Lincoln has ten sides, and that at Worcester is circular; most are groined over, and some, as Salisbury, Wells, Lincoln, Worcester, &c., depend on a single slight vaulting shaft for the support of the massive vaulting. This picturesque plan is almost exclusively English.

Charnel House (Med. Lat. *carnarium*, Fr. *ossuaire*), a place for depositing the bones which might be thrown up in digging graves. Sometimes, as at Gloucester, Hythe, and Ripon, it was a portion of the crypt; sometimes, as at Old St Paul's and Worcester (both now destroyed), it was a separate building in the church-yard; sometimes chantry chapels were attached to these buildings. M. Viollet-le-Duc has given two very curious examples of *ossuaires*,—one from Fleurance, the other from Faouet.

Choir (Lat. *chorus*, Ital. *coro*, Fr. *chœur*, Ger. *Chor*, Old English, *quire, quere*), that part of a church or monastery where the breviary services or "horæ" are chanted.

Ciborium (Fr. *baldaquin*, Ital. *baldacchino*), a tabernacle or vaulted canopy supported on shafts standing over the high altar. Gervase of Canterbury calls every bay of the quire there a ciborium, probably because the groining rose and formed a sort of canopy over each bay.

Cinquefoil, a sinking or perforation like a flower of five points or leaves, as a quatrefoil is of four. The points are sometimes in a circle, as in the lower windows at Lincoln, and sometimes form the cusping of a head.

Cleithral (Gr. κλεῖθρον, an enclosed or shut-up place), is applied to a covered Greek temple, in contradistinction to *Hypæthral*, which designates one that is uncovered; the roof of a cleithral temple completely covers or encloses it.

Clerestory, Clearstory (Ital. *chiaro piano*, Fr. *clairevoie, claire étage*, Ger. *Lichtgaden*). When the middle of the nave of a church rises above the aisles and is pierced with windows, the upper story is thus called. Sometimes these windows are very small, being mere quatrefoils, or spherical triangles. In large buildings, however, they are important objects, both for beauty and utility. The window of the clerestories of Norman work, even in large churches, are of less importance than in the later styles. In Early English they became larger; and in the Decorated they are more important still, being lengthened as the triforium diminishes. In Perpendicular work the latter often disappears altogether, and in many later churches, as at Taunton, and many churches in Norfolk and Suffolk, the clerestories are close ranges of windows.

Cloister (Lat. *claustrum*, Ital. *chiostro*, Fr. *cloître*, Ger. *Kloster*), an enclosed square, like the atrium of a Roman house, with a walk or ambulatory round, sheltered by a roof generally groined, and by tracery windows, which were more or less glazed. (See separate article.)

Close, the precinct of a cathedral or abbey. Sometimes the walls are traceable, but now generally the boundary is only known by tradition.

Coffer, a deep panel in a ceiling.

Column (Lat. *columna*), a tapering cylindrical mass, placed vertically on a level stylobate, in some cases with a spreading congeries of mouldings called a base, and having always at its upper and smaller end a dilating mass called a capital. Columns are either insulated or attached. They are said to be attached or engaged when they form part of a wall, projecting one half or more, but not the whole, of their substance. For the columns of different styles and orders of architecture, see the general article, *supra*.

Consol or Console, a bracket or truss, generally with scrolls or volutes at the two ends, of unequal size and contrasted, but connected by a flowing line from the back of the upper one to the inner convolving face of the lower.

Coping (Ital. *coperto, corona*, Fr. *chaperon*), the capping (whence the name is probably derived) or covering of a wall. This is of stone, weathered to throw off the wet. In Norman times, as far as can be judged from the little there is left, it was generally plain and flat, and projected over the wall with a throating to form a drip. Afterwards it assumed a torus or bowtell at the top, and became deeper, and in the Decorated period there were generally several sets-off. The copings in the late Perpendicular period assumed something of the wavy section of the buttress caps, and mitred round the sides of the embrasure, as well as the top and bottom.

Corbel (from the low Latin *corbeyus*, a basket, Ital. *mensola*, Fr. *corbeau, cul-de-lampe*, Ger. *Kragstein*), the name in mediæval architecture for a piece of stone jutting out of a wall to carry any superincumbent weight. A piece of timber projecting in the same way was called a tassel or a bragger. Thus the carved ornaments from which the vaulting shafts spring at Lincoln are corbels. Norman corbels are generally plain. In the Early English period they are sometimes elaborately carved, as at Lincoln above cited, and sometimes more simply so, as at Stone. They sometimes end with a point apparently growing into the wall, or forming a knot, as at Winchester, and often are supported by angels and other figures. In the later periods the foliage or ornaments resemble those in the capitals. (See Capital.)

Corbel Table, a projecting cornice or parapet, supported by a range of corbels a short distance apart, which carry a moulding, above which is a plain piece of projecting wall forming a parapet, and covered by a coping. Sometimes small arches are thrown across from corbel to corbel, to carry the projection.

Corbie Steps, a Scottish term for the steps formed up the sides of the gable by breaking the coping into short horizontal pieces.

Cornice (Fr. *corniche*, Ger. *Kranz*), the projection at the top of a wall finished by a blocking-course, common in classic architecture. In Norman times, the wall finished with a corbel table, which carried a portion of plain projecting work, which was finished by a coping, and the whole formed a Parapet. In Early English times the parapet was much the same, but the work was executed in a much better way, especially the small arches connecting the corbels. In the Decorated period the corbel table was nearly abandoned, and a large hollow, with one or two subordinate mouldings, substituted; this was sometimes filled with the ball flowers, and sometimes with running foliages. In the Perpendicular style, the parapet frequently did not project beyond the wall-line below; the moulding then became a string (though often improperly called a cornice), and was ornamented by a quatrefoil or small rosettes set at equal intervals immediately under the battlements. In many French examples the moulded string is very bold, and enriched with foliage ornaments.

CORONA, a term applied to the deep vertical face of the projected part of the cornice between the bed-mould and the covering mouldings.

COVE—COVING. The moulding called the cavetto,—or the scotia inverted,—on a large scale, and not as a mere moulding in the composition of a cornice, is called a cove or a coving.

CRENELLE, a word generally considered to mean an embrasure of a battlement, but latterly proved to apply to the whole system of defence by battlements. In mediæval times no one could "crenellate" a building without special licence from his supreme lord. (See BATTLEMENT, EMBRASURE.)

CRESTING, an ornamental finish in the wall or ridge of a building, which is common on the Continent. An example occurs at Exeter Cathedral, the ridge of which is ornamented with a range of small *fleurs-de-lis* in lead.

CROCKET (Ital. *uncinetto*, Fr. *crochet*, *crosse*, Ger. *Häklein*, *Knollen*), an ornament running up the sides of gablets, hood-moulds, pinnacles, spires; generally a winding stem like a creeping plant, with flowers or leaves projecting at intervals, and terminating in a finial.

CROP (Ang.-Sax. *crop*), the top of anything. A word anciently used for a FINIAL, which see.

CROSS. This religious symbol is almost always placed on the ends of gables, the summit of spires, and other conspicuous places of old churches. In early times it was generally very plain, often a simple cross in a circle, as at Beverley. Sometimes they take the form of a light cross crosslet, or a cross in a square. In the Decorated and later styles they became richly floriated, and assumed an endless variety of forms. Of *memorial* crosses the finest examples are the Eleanor crosses, erected by Edward I. Of these a few yet remain, one of which has recently been re-erected at Charing Cross. *Preaching* crosses were often set up by the wayside as stations for preaching; the most noted is that in front of St Paul's. The finest remaining *sepulchral* crosses are the old elaborately-carved examples found in Ireland.

CROSS-AISLE, an old name for a transept.

CROSS-SPRINGER, the transverse ribs of a vault.

CROW-STEPS. See CORBIE STEPS.

CROW STONE, the upper stone of a gable; see also as last.

CRYPT (Lat. *crypta*, Ital. *volto sotterraneo*, Fr. *crypte*, Ger. *Gruft*), a vaulted apartment of greater or less size, usually under the choir. (See separate article.)

CUPOLA (Ital. *cupo*, concave, profound), a spherical or spheroidal covering to a building, or to any part of it.

CUSP (Fr. *feuille*, Ital. *cuspide*, Ger. *Knopf*), the point where the foliations of tracery intersect. The earliest example of a plain cusp is probably that at Pythagoras School, at Cambridge,—of an ornamented cusp at Ely Cathedral, where a small roll, with a rosette at the end, is formed at the termination of a cusp. In the later styles the terminations of the cusps were more richly decorated; they also sometimes terminate not only in leaves or foliages, but in rosettes, heads, and other fanciful ornaments.

CYCLOSTYLE (Gr. κύκλος, a circle, and στῦλος, a column). A structure composed of a circular range of columns without a core is cyclostylar; with a core the range would be a peristyle. This is the species of edifice called by Vitruvius Monopteral. (See MONOPTEROS.)

CYMA (Gr. κῦμα, a wave), the name of a moulding of very frequent use. It is a simple, waved line, concave at one end and convex at the other, like an Italic *f*. When the concave part is uppermost it is called a cyma-recta; but if the convexity appear above, and the concavity below, it is then a cyma-reversa.

CYMATIUM. When the crowning moulding of an entablature is of the cyma form, it is termed the Cymatium.

CYRTO-PROSTYLE. An alternation of CYRTOSTYLE (*q.v.*), but indicating more clearly than Cyrtostyle does an external projection.

CYRTOSTYLE (Gr. κυρτός, convex, and στῦλος, a column), a circular projecting portico. Such are those of the transept entrances to St Paul's Cathedral.

DADO or DIE, the vertical face of an insulated pedestal between the base and cornice or surbase. It is extended also to the similar part of all stereobates which are arranged like pedestals in Roman and Italian architecture.

DAIS (Fr. *dais*, *estrade*, Ital. *predella*), a part of the floor at the end of a mediæval hall, raised a step above the rest of the building. On this the lord of the mansion dined with his friends at the great table, apart from the retainers and servants. In mediæval halls there was generally a deep recessed bay window at one or at each end of the dais, supposed to be for retirement, or greater privacy than the open hall could afford. In France the word is understood as a canopy or hanging over a seat; probably the name was given from the fact that the seats of great men were then surmounted by such an ornament.

DECASTYLE (Gr. δέκα, ten, and στῦλος, a column), a portico of ten columns in front.

DENTIL (Lat. *dens*, a tooth). The cogged or toothed member, common in the bed-mould of a Corinthian entablature, is said to be dentilled, and each cog or tooth is called a dentil.

DEPRESSED ARCHES or DROP ARCHES, those of less pitch than the equilateral.

DESIGN. The plans, elevations, sections, and whatever other drawings may be necessary for an edifice, exhibit the design, the term *plan* having a restricted application to a technical portion of the design. (See PLAN.)

DETAIL. As used by architects, detail means the smaller parts into which a composition may be divided. It is applied generally to mouldings and other enrichments, and again to their minutiæ.

DIAMETERS. The diameters of the lower and upper ends of the shaft of a column are called its inferior and superior diameters respectively; the former is the greatest, the latter the least diameter of the shaft.

DIAPER (Ital. *diaspro*, Fr. *diaspré*, Ger. *Geblumte*), a method of decorating a wall, panel, stained glass, or any plain surface, by covering it with a continuous design of flowers, rosettes, &c., either in squares or lozenges, or some geometrical form resembling the pattern of a diapered table-cloth, from which, in fact (drap d'Ypres), the name is supposed by some to have been derived.

DIASTYLE (Gr. διά, through, and στῦλος, a column), a spacious intercolumniation, to which three diameters are assigned. (See EUSTYLE.)

DIPTEROS (Gr. δίς, twice, and πτερόν, a wing), a double-winged temple. The Greeks are said to have constructed temples with two ranges of columns all round, which were called dipteroi. A portico projecting two columns and their interspaces is of dipteral or pseudo-dipteral arrangement.

DISCHARGING ARCH, an arch over the opening of a door or window, to discharge or relieve the superincumbent weight from pressing on the freestone.

DISTEMPER. See FRESCO.

DISTYLE (Gr. δίς, twice, and στῦλος, a column), a portico of two columns. This term is not generally applied to the mere porch with two columns, but to describe a portico with two columns *in antis*.

DITRIGLYPH, an intercolumniation in the Doric order, of two triglyphs. (See TRIGLYPH.)

DODECASTYLE (Gr. δώδεκα, twelve, and στῦλος, a column), a portico of twelve columns in front. The lower one of the west front of St Paul's Cathedral is of twelve columns, but they are coupled, making the arrangement pseudo-dodecastyle. The Chamber of Deputies in Paris has a true dodecastyle.

DOG-TOOTH, a favourite enrichment used from the latter part of the Norman period to the early part of the Decorated. It is in the form of a four-leaved flower, the centre of which projects, and probably was named from its resemblance to the dog-toothed violet.

DOME (Gr. δῶμα, a structure of any kind, Lat. *domus*, a house or temple), a cupola or inverted cup on a building. The application of this term to its generally-received purpose is from the Italian custom of calling an archiepiscopal church, by way of eminence, *Il duomo*, the temple; for to one of that rank, the cathedral of Florence, the cupola was first applied in modern practice. The Italians themselves never call a cupola a dome: it is on this side of the Alps the application has arisen, from the circumstance, it would appear, that the Italians use the term with reference to those structures whose most distinguishing feature is the cupola, tholus, or (as we now call it) dome. (See CUPOLA.)

DONJON, the principal tower of a castle. (See KEEP.)

DORMER BEAM or DORMANT BEAM, said to be a tie-beam, but more probably, as its name imports, a sleeper.

DORMER WINDOW (Fr. *lucarne*, Ital. *abbaino*, Ger. *Dachfenster*), a window belonging to a room in a roof, which consequently projects from it with a valley gutter on each side. They are said not to be earlier than the 14th century. In Germany there are often several rows of dormers, one above the other. In Italian Gothic they are very rare; in fact, the former have an unusually steep roof, while in the latter country, where the Italian tile is used, the roofs are rather flat.

DORMITORY (Fr. *dortoir*, Ital. *dormitorio*, Ger. *Schlafgemach*), the place where the monks slept at night. It was sometimes one long room like a barrack, and sometimes divided into a succession of small chambers or cells. The dormitory was generally on the first floor, and connected with the church, so that it was not necessary to go out of doors to attend the nocturnal services. In the large houses of the late Perpendicular period, and also in some of the Elizabethan, the entire upper story in the roof formed one large apartment, said to have been a place for exercise in wet weather, and also for a dormitory for the retainers of the household, or those of visitors.

DOSSEL or DORSAL. See REREDOS

DRIPSTONE, the moulding or cornice which acts as a canopy to doors and windows. Horizontal running mouldings, are sometimes called tablets, and sometimes dripstones.

DROP ARCHES. See DEPRESSED ARCHES.

Dungeon, the prison in a castle keep, so called because the Norman name for the latter is donjon, and the dungeons or prisons are generally in its lowest story. (See Keep.)

Echauguette. See Bartizan.

Echinus (Gr. ἐχῖνος, an egg), a moulding of eccentric curve, generally cut (when it is carved) into the forms of eggs and anchors alternating, whence the moulding is called by the name of the more conspicuous. It is the same as Ovolo, *q.v.*

Element, the outline of the design of a Decorated window, on which the centres for the tracery are formed. These centres will all be found to fall on points which, in some way or other, will be equimultiples of parts of the openings. Before any one can draw tracery well, or understand even the principles of its composition, he must give much attention to the study of the element. (See Tracery.)

Elevation, the front *façade*, as the French term it, of a structure, a geometrical drawing of the external upright parts of a building.

Embrasure, the opening in a battlement between the two raised solid portions or merlons, sometimes called a crenelle. (See Battlement, Crenelle.)

Enceinte, a French term for the close or precinct of a cathedral, abbey, castle, &c.

Entablature, or **Intablature** (Lat. *in*, upon, and *tabula*, a tablet), the superimposed horizontal mass in a columnar ordinance, which rests upon the tablet or abacus of a column. It is conventionally composed of three parts, architrave, frieze, and cornice.

Entail, Entayle, sculptured ornaments, generally of rich design, most probably derived from the Italian *intaglio*.

Entasis, the swelling of a column, &c. In mediæval architecture, some spires, particularly those called "broach spires," have a slight swelling in the sides, but no more than to make them look straight; for, from a particular "deceptio visus," that which is quite straight, when viewed at a height, looks hollow.

Épi, the French term for a light finial, generally of metal, but sometimes of terra cotta, forming the termination of a pointed roof or spire.

Epistylium, or **Epistyle** (Gr. ἐπί, upon, and στῦλος, a column). This term may with propriety be applied to the whole entablature, with which it is synonymous; but it is restricted in use to the architrave or lowest member of the entablature.

Escape, an equivalent for the term Apophyge, *q.v.*

Escutcheon (Lat. *scutum*, Ital. *scudo*, Fr. *écusson*, Ger. *Wappenschild*), a term for the shields used on tombs in the spandrils of doors or in string-courses. Also the ornamented plates from the centre of which door-rings, knockers, &c., are suspended, or which protect the wood of the key-hole from the wear of the key. In mediæval times these were often worked in a very beautiful manner.

Estrade, a French term for a raised platform. (See Dais.)

Eustyle (Gr. εὖ, well, and στῦλος, a column), a species of intercolumniation, to which a proportion of two diameters and a quarter is assigned. This term, together with the others of similar import—pycnostyle, systyle, diastyle, and aræostyle—referring to the distances of columns from one another in composition, is from Vitruvius, who assigns to each the space it is to express. It will be seen, however, by reference to them individually, that the words themselves, though perhaps sufficiently applicable, convey no idea of an exactly defined space, and by reference to the columnar structures of the ancients, that no attention was paid by them to such limitations. It follows, then, that the proportions assigned to each are purely conventional, and may or may not be attended to without vitiating the power of applying the terms. Eustyle means the best or most beautiful arrangement; but as the effect of a columnar composition depends on many things besides the diameter of the columns, the same proportioned intercolumniation would look well or ill according to those other circumstances, so that the limitation of eustyle to two diameters and a quarter is absurd.

Façade. See Elevation.

Faite, the French term for the ridge of a roof.

Faitière, the ornament running along the ridge of a building (See Crestino.)

Fan Tracery. See Groined Vaulting.

Fascia (Lat. a band.) The narrow vertical bands or broad fillets into which the architraves of Corinthian and Ionic entablatures are divided are called fasciæ; and the term is generally applied to any similar member in architecture.

Feathering. See Cusp.

Femerell, properly **Fumerell**, a sort of lantern in the ridge of a hall (when the fire was in the middle of the floor and not in a chimney) for the purpose of letting out the smoke.

Fenestral, a frame or "chassis," on which oiled paper or thin cloth was strained to keep out wind and rain when the windows were not glazed.

Feretory, a sort of parclose which enclosed the feretrum, shrine, or tomb, as in Henry VII.'s chapel.

Fillet (Fr. *filet*, *listel*, Ital. *listello*, Ger. *Binde*), a narrow vertical band or listel, of frequent use in congeries of mouldings, to separate and combine them, and also to give breadth and firmness to the upper edge of a crowning cyma or cavetto, as in an external cornice. The narrow slips or breadths between the flutes of Corinthian and Ionic columns are also called fillets. In mediæval work, the fillet is a small, flat, projecting square, chiefly used to separate hollows and rounds, and often found in the outer parts of shafts and bowtells. In this situation the centre fillet has been termed a keel, and the two side ones wings; but apparently this is not an ancient usage.

Finial (Fr. *fleuron*), the flower or bunch of flowers with which a spire, pinnacle, gablet, canopy, &c., generally terminates. Where there are crockets, the finial generally bears as close a resemblance as possible to them in point of design. They are found in early work where there are no crockets. The simplest form more resembles a bud about to burst than an open flower. They soon became more elaborate, as at Lincoln, and still more, as at Westminster and the Hotel Cluny at Paris. Many Perpendicular finials are like four crockets bound together. Almost every known example of a finial has a sort of necking separating it from the parts below. (See Épi.)

Flamboyant, a name applied to the Third Pointed style in France (*ogive tertiale*), which seems to have been developed from the Second, as our Perpendicular was from the Decorated. The great characteristic is, that the element of the tracery flows upwards in long wavy divisions like flames of fire. In most cases, also, every division has only one cusp on each side, however long the division may be. The mouldings seem to be as much inferior to those of the preceding period, as our Perpendicular mouldings were to the Early English, a fact which seems to show that the decadence of Gothic architecture was not confined to one country.

Flèche (Ital. *aguglia*), a general term in French architecture for a spire, but more particularly used for the small slender erection rising from the intersection of the nave and transepts in cathedrals and large churches, and carrying the sanctus bell.

Flute, a concave channel. Columns whose shafts are channelled are said to be fluted, and the flutes are collectively called flutings.

Foliation. See Cusp.

Font, the vessel used in the rite of baptism. The earliest extant is supposed to be that in which Constantine is said to have been baptised; this is a porphyry *labrum* from a Roman bath. Those in the baptisteries in Italy are all large, and were intended for immersion; as time went on, they seem to have become smaller. What they were in Saxon times is uncertain, though it is not improbable that some of the plain examples, called Norman, may have been of earlier date. Norman fonts are sometimes mere plain, hollow cylinders, generally a little smaller below than above; others are massive squares, supported on a thick stem, round which sometimes there are smaller shafts. In the Early English this form is still pursued, and the shafts are detached; sometimes, however, they are hexagonal and octagonal, and in this and the later styles assume the form of a vessel on a stem. Norman fonts have frequently curious carvings on them, approaching the grotesque; in later times the foliages, &c., partook absolutely of the character of those used in other architectural details of their respective periods. The font is usually placed close to a pillar near the entrance, generally that nearest but one to the tower in the south arcade, or, in large buildings, in the middle of the nave, opposite the entrance porch, and sometimes in a separate building. (See Baptistery.)

Foot-Stall, a word supposed to be a literal translation of *piédestal*, or pedestal, the lower part of a pier. (See Base, Patin.)

Formeret, the half ribs against the walls in a groined-ceiling.

Fratery, Frater House, supposed to be the hall where the friars met for dinner or other purposes; the same as *refectory* among the monks.

Free-stone (Fr. *pierre de taille*, Ital. *pietra molle*), stone used for mouldings, tracery, and other work required to be executed with the chisel. The oolitic stones are generally so called, although in some countries the soft sandstones are so used, and in some churches an indurated chalk called clunch is employed for internal lining and for carving.

Fresco, the method of painting on a wall while the plastering is wet. The colour penetrates through the material, which therefore will bear rubbing or cleaning to almost any extent. The transparency, the chiaroscuro, and lucidity, as well as force, which can be obtained by this method, cannot be conceived unless the frescoes of Fra Angelico or Raffaelle are studied. The word, however, is often applied improperly to mediæval delineations in ancient churches, which are only painted on the surface in distemper or body colour, mixed with size or white of egg, which gives them an opaque effect.

Frieze (Ital. *fregio*, from the Lat. *Phrygionius*, enriched or embroidered), that portion of an entablature between the cornice above and the architrave below. It derives its name from being the recipient of the sculptured enrichments either of foliage or figures which may be relevant to the object of the structure. The frieze is also called the ZOÖPHORUS, *q.v.*

FRONTISPIECE, the front or principal elevation of a structure. This term, however, is generally restricted in application to a Decorated entrance.

FUMEREL. See FEMERELL.

GABLE, sometimes *Gavil* (Fr. *pignon*, Ital. *colma*, Ger. *Giebel*). When a roof is not hipped or returned on itself at the ends, its ends are stopped by carrying up the walls under them in the triangular form of the roof itself. This is called the gable, or, in the case of the ornamental and ornamented gable, the pediment. Of course gables follow the angles of the slope of the roof, and differ in the various styles. In Norman work they are generally about half pitch; in Early English, seldom less than equilateral, and often more. In Decorated work they become lower, and still more so in the Perpendicular style. In all important buildings they are finished with copings or parapets. In early times the copings were nearly flat. In the later styles gables are often surmounted with battlements, or enriched with crockets; they are also often panelled or perforated, sometimes very richly. The gables in ecclesiastical buildings are mostly terminated with a cross; in others, by a finial or pinnacle. In later times the parapets or copings were broken into a sort of steps, called *corbie steps*. In buildings of less pretension, the tiles or other roof covering passed over the front of the wall, which then, of course, had no coping. In this case the outer pair of rafters were concealed by moulded or carved verge boards. (See BATTLEMENT, COPING, CORBIE STEPS, PARAPET, VERGE BOARD, &c.)

GABLE WINDOW, a term sometimes applied to the large window under a gable, but more properly to the windows in the gable itself.

GABLED TOWERS, those which are finished with gables instead of parapets, as at Sompting. Many of the German Romanesque towers are gabled.

GABLETS, triangular terminations to buttresses, much in use in the Early English and Decorated periods, after which the buttresses generally terminate in pinnacles. The Early English gablets are generally plain, and very sharp in pitch. In the Decorated period they are often enriched with panelling and crockets. They are sometimes finished with small crosses, but oftener with finials.

GALILEE. This name is said to be derived from the Scriptural expression, "Galilee of the Gentiles." Galilees are supposed to have been used sometimes as courts of law, but chiefly for penitents not yet admitted to the body of the church. At Durham the galilee is a chapel at the main entrance into the nave.

GALLERY, any long passage looking down into another part of a building, or into the court outside. In like manner, any stage erected to carry a rood or an organ, or to receive spectators, was latterly called a gallery, though originally a loft. In later times the name was given to any very long rooms, particularly those intended for purposes of state. (See LOFT, TRIFORIUM.)

GARGOYLE or GURGOYLE (Fr. *gargouille*, *canon*, *lanceur*, Ital. *doccia di gronda*, Ger. *Ausguss*), the carved termination to a spout which conveyed away the water from the gutters, supposed to be called so from the gurgling noise made by the water passing through it. Gargoyles are mostly grotesque figures.

GARRETTING, properly GALLETTING, from gallet, a small piece of stone chipped off by the chisel. A method of protecting the mortar joints in rough walls by sticking in chips of stone while the mortar is wet.

GATE-HOUSE, a building forming the entrance to a town, the door of an abbey, or the enceinte of a castle or other important edifice. They generally had a large gateway protected by a gate, and also a portcullis, over which were battlemented parapets with holes (machicolations) for throwing down darts, melted lead, or hot sand, on the besiegers. Gatehouses always had a lodge, with apartments for the porter, and guard-rooms for the soldiers; and generally rooms over for the officers, and often places for prisoners beneath. They are sometimes open in the rear, as at Cooling Castle, and often have doors with portcullises, &c., on both sides, in case the enemy should scale the walls, and attack them both in front and rear. In this case, the space between, on the ground floor, was generally groined over, with holes for missile weapons.

GLYPH, a vertical channel in a frieze. (See TRIGLYPH.)

GRADINO (Ital. dim. of *gradus*, a step). Architects frequently apply the plural of this term, *gradini*, to such series of great steps as are found at the mausoleum at Halicarnassus.

GRANGE, a word derived from the French, signifying a large barn or granary. They were usually long buildings with high wooden roofs, sometimes divided by posts or columns into a sort of nave and aisles, and with walls strongly buttressed. In England the term is applied not only to the barns, but to the whole of the buildings which formed the detached farms belonging to the monasteries; in most cases there was a chapel either included among these or standing apart as a separate edifice.

GRIFFE, a French term for an ornament at the angles of the base of early pillars, for which we have no proper equivalent. It first consisted of a single leaf, which became more elaborate, and was, no doubt, the origin of the foliated bases.

GRILLE, the iron work forming the enclosure screen to a chapel, or the protecting railing to a tomb or shrine; more commonly found in France than in England. Our best example, perhaps, is that round the tomb of Queen Eleanor in Westminster Abbey. They are of wrought iron, ornamented by the swage and punch, and put together either by rivets or clips.

GROIN, by some described as the line of intersection of two vaults where they cross each other, which others call *the groin point;* by others the curved section or spandril of such vaulting is called a groin, and by others the whole system of vaulting is so named.

GROIN ARCH (Fr. *arc doubleau*), the cross rib in the later styles of groining, passing at right angles from wall to wall, and dividing the vault into bays or *travées*.

GROIN CEILING, a ceiling to a building composed of oak ribs, the spandrils of which are filled in with narrow, thin slips of wood. There are several in England; one at the Early English church at Warmington, and one at Winchester Cathedral, exactly resembling those of stone.

GROIN CENTERING. In groining without ribs, the whole surface is supported by centering during the erection of the vaulting. In ribbed work the stone ribs only are supported by timber ribs during the progress of the work, any light stuff being used while filling in the spandrils.

GROIN POINT, the name give by workmen to the arris or line of intersection of one vault with another where there are no ribs.

GROIN RIB (Fr. *nerf d'arête*, Ital. *costola*, Ger. *Rippe*), the rib which conceals the groin point or joints, where the spandrils intersect.

GROINED VAULTING (Lat. *fornix*, *testudo*, Fr. *voûte d'arête*, Ital. *fornice*), the system of covering a building with stone vaults which cross and intersect each other, as opposed to the barrel vaulting (*voûte de berceau*), or series of arches placed side by side. The earliest groins are plain, without any ribs, except occasionally a sort of wide band from wall to wall, to strengthen the construction. In later Norman times ribs were added on the line of intersection of the spandrils, crossing each other, and having a boss as a key common to both; these ribs the French authors call *nerfs en ogive*. Their introduction, however, caused an entire change in the system of vaulting; instead of arches of uniform thickness and great weight, these ribs were first put up as the main construction, and spandrils (*remplissage*) of the lightest and thinnest possible material placed upon them, the haunches only being loaded sufficiently to counterbalance the pressure from the crown. Shortly after, half ribs against the walls (*formerets*) were introduced to carry the spandrils without cutting into the walling, and to add to the appearance. The work was now not treated as continued vaulting, but as divided into days (*travees*), and it was formed by keeping up the ogive or intersecting ribs and their bosses; a sort of construction having some affinity to the dome was formed, which added much to the strength of the groining. Of course the top of the soffit or ridge of the vault was not horizontal, but rose from the level of the top of the formeret-rib to the boss and fell again; but this could not be perceived from below. As this system of construction got more into use, and as the vaults were required to be of greater span and of higher pitch, the spandrils became larger, and wanted more support. To give this another set of ribs was introduced, passing from the springers of the ogive ribs, and going to about half-way between these and the ogive, and meeting on the ridge of the vault; these intermediate ribs are called by the French *tiercerons*, and began to come into use in the transition from Early English to Decorated. About the same period a system of vaulting came into use called *hexpartite*, from the fact that every bay is divided into six compartments instead of four. It was invented to cover the naves of churches of unusual width. The filling of the spandrils in this style is very peculiar; and, where the different compartments meet at the ridge, some pieces of harder stone have been used, which have rather a pleasing effect. The arches against the wall being of smaller span than the main arches, cause the centre springers to be perpendicular and parallel for some height, and the spandrils themselves are very hollow. As styles progressed, and the desire for greater richness increased, another series of ribs called *liernes*, was introduced; these passed cross-ways from the *ogives* to the *tiercerons*, and thence to the *doubleaux*, dividing the spandrils nearly horizontally. These various systems increased in the Perpendicular period, so that the vaults were quite a network of ribs, and led at last to the Tudor, or, as it is called by many, *fan tracery* vaulting. In this system the ribs are no part of the real construction, but are merely carved upon the voussoirs, which form the actual vaulting. Fan Tracery is so called because the ribs radiate from the springers, and spread out like the sticks of a fan. These later methods are not strictly groins, for the pendentives are not square on plan, but circular, and there is therefore no arris intersection or GROIN POINT (which see)

GROINS, WELSH, or UNDERPITCH. When the main longitudinal vault of any groining is higher than the cross or transverse vaults which run from the windows, the system of vaulting is called underpitch groining, or, as termed by the workmen, Welsh groining. A very fine example is at St George's Chapel, Windsor.

GROUND TABLE. See BASE OF A WALL.

GUILLOCHE or GUILLOCHOS (Gr. γυῖον, a member, and λόχος, a snare), an interlaced ornament like network, used most frequently to enrich the torus.

GUTTÆ (Lat. drops). The small cylindrical drops used to enrich the mutules and regulæ of the Doric entablature are so called.

GUTTER, the channel for carrying off rain-water. The mediæval gutters differed little from others, except that they are often hollows sunk in the top of stone cornices, in which case they are generally called *channels* in English, and *chéneaux* in French.

HAGIOSCOPE, a term derived from the Greek, improperly used to describe certain oblique openings in the mediæval buildings for the purpose of seeing the altar. (See SQUINT.)

HALL (Fr. *salle*, *salon*, Ital. *sala*, *salone*, Ger. *Saal*), the principal apartment in the large dwellings of the Middle Ages used for the purposes of receptions, feasts, &c. In the Norman castle the hall was generally in the keep above the ground floor, where the retainers lived, the basement being devoted to stores and dungeons for confining prisoners. Later halls, indeed some Norman halls (not in castles), are generally on the ground floor, as at Westminster, approached by a porch either at the end, as in this last example, or at the side, as at Guildhall, London, having at one end a raised DAIS (which see) or Estrade. The roofs are generally open, and more or less ornamented. In the middle of these was an opening to let out the smoke (see LOUVRE, FEMERELL), though in later times the halls have large chimney places with funnels or chimney shafts for this purpose. At this period there were usually two deeply recessed bay windows at each end of the dais, and doors leading into the withdrawing-rooms or the ladies' apartments; they are also generally wainscoted with oak, in small panels, to the height of five or six feet, the panels often being enriched. Westminster Hall was originally divided into three parts, like a nave and side aisles, as are some on the Continent.

HELIX (Gr. ἕλιξ, a wreath or ringlet), used synonymously with CAULICULUS, *q.v.* Its plural is Helices.

HERRING-BONE WORK, bricks or other materials arranged diagonally in building.

HEXASTYLE (Gr. ἕξ, six, and στῦλος, a column). A portico of six columns in front is of this description. Most of the churches in London which have porticoes have hexaprostyles.

HIGH ALTAR, the principal altar in a cathedral or church. Where there is a second, it is generally at the end of the choir or chancel, not in the Lady Chapel. At St Albans it stood at the end of the nave, close to the choir screen.

HIP-KNOB, the finial on the hip of a roof, or between the barge boards of a gable.

HOOD-MOULD, a word used to signify the drip-stone or label over a window or door opening, whether inside or out; but it seems more properly to be applied to the mouldings at the arris of the arch at the inner side of such opening. Sometimes these assume the form of a label, and have jamb-shafts. Frequently the soffit is slightly hollowed and finishes with an arris. (See DRIPSTONE, LABEL.)

HOTEL DE VILLE (Ital. *broletto*, *palazzo*, *communale*), the town-hall or guild-hall, in France, Germany, and Northern Italy. The building in general serves for the administration of justice, the receipt of town dues, the regulation of markets, the residence of magistrates, barracks for police, prisons, and all other fiscal purposes. As may be imagined, they differ very much in different towns, but they have almost invariably attached to them, or closely adjacent, a large clock-tower (*beffroi*), containing one or more bells, for calling the people together on special occasions.

HOTEL DIEU (Fr. *maison dieu*, Ital. *ospedale*, *lo spedale*), the name for an hospital in mediæval times. In England there are but few remains of these buildings, one of which is at Dover; abroad there are many. The most celebrated is the one at Angers, described by Parker. They do not seem to differ much in arrangement of plan from those in modern days—the accommodation for the chaplain, medicine, nurses, stores, &c., being much the same in all ages, except that in some of the earlier, instead of the sick being placed in long wards like galleries, as is now done, they occupied large buildings, with naves and side aisles like churches. The reader is referred to the works of Parker, Viollet-le-Duc, and Verdier and Cattois, for further details.

HYPÆTHROS (Gr. ὑπό, under, and αἰθήρ, the air), a temple open to the air, or uncovered. The term may be the more easily understood by supposing the roof removed from over the nave of a church in which columns or piers go up from the floor to the ceiling, leaving the aisles still covered.

HYPOGEA (Gr. ὑπο, under, and γῆ, the earth), constructions under the surface of the earth, or in the sides of a hill or mountain.

HYPOTRACHELIUM (Gr. ὑπό, under, and τράχηλος, the neck), the moulding or the groove at the junction of the shaft with the capital of a column. In some styles the hypotrachelium is a projecting fillet or moulding, and in others, as the Doric, it is composed of a channel or groove, and sometimes of more than one.

ICHNOGRAPHY (Gr. ἴχνος, a footstep or track, and γραφή, a description or representation), the drawing of a plan, or representation of the site of an object on a horizontal plane.

IMPOST, a term in classic architecture for the horizontal mouldings of piers or pilasters, from the top of which the archivolts or mouldings which go round the arch spring. The word is scarcely applicable to mediæval architecture, as the mouldings in general spring from the capital of a shaft, or from a corbel; or they continue without breaking down to the base, or till they are stopped by a chamfer or a regular base moulding, or they die into a plain shaft, or at any rate one of different section.

INTERCOLUMNIATION, the distance from column to column, the clear space between columns.

INTERLACED ARCHES, arches where one passes over two openings, and they consequently cut or intersect each other.

IRON WORK, in mediæval architecture, as an ornament is chiefly confined to the hinges, &c., of doors and of church chests, &c. Specimens of Norman iron work are very rare. Early English specimens are numerous, and very elaborate. In some instances not only do the hinges become a mass of scroll work, but the surface of the doors is covered by similar ornaments. In both these periods the design evidently partakes of the feeling exhibited in the stone or wood carving. In the Decorated period the scroll work is more graceful, and, like the foliage of the time, more natural. As styles progressed, there was a greater desire that the framing of the doors should be richer, and the ledges were chamfered or raised, then panelled, and at last the doors became a mass of scroll panelling. This, of course, interfered with the design of the hinges, the ornamentation of which gradually became unusual. In almost all styles the smaller and less important doors had merely plain strap hinges, terminating in a few bent scrolls, and latterly in *fleurs-de-lis*. Escutcheon and ring handles, and the other furniture, partook more or less of the character of the time. On the Continent the knockers are very elaborate. At all periods doors have been ornamented with nails having projecting heads, sometimes square, sometimes polygonal, and sometimes ornamented with roses, &c. The iron work of windows is generally plain, and the ornament confined to simple *fleur-de-lis* heads to the stancheons. The iron work of screens enclosing tombs and chapels is noticed under GRILLE, *q.v.*

JAMB, the side-post or lining of a doorway or other aperture. The jambs of a window outside the frame are called Reveals.

JAMB-SHAFT. Small shafts to doors and windows with caps and bases; when in the inside arris of the jamb of a window they are sometimes called Esconsons.

JAMBETTE, a French term for the upright ashlar piece between the inside of the plate and the rafters.

JUBE, one of the names of the ambo or reading desk in the early Christian church. In later times, a term especially applied to the rood-loft or gallery over the screen, whence the words "Jube, Domine, benedicere," &c., were read.

KEEL-MOULDING, a round on which there is a small fillet, somewhat like the keel of a ship. It is common in the Early English and Decorated styles.

KEEP (Fr. *donjon*), the inmost and strongest part of a mediæval castle, answering to the citadel of modern times. The arrangement is said to have originated with Gundulf, the celebrated bishop of Rochester. The Norman keep is generally a very massive square tower, the basement or stories partly below ground being used for stores and prisons. The main story is generally a great deal above ground level, with a projecting entrance, approached by a flight of steps and drawbridge. This floor is generally supposed to have been the guard-room or place for the soldiery; above this was the hall, which generally extended over the whole area of the building, and is sometime separated by columns; above this are other apartments for the residents. There are winding staircases in the angles of the buildings, and passages and small chambers in the thickness of the walls. The keep was intended for the last refuge, in case the outworks were scaled and the other buildings stormed. There is generally a well in a mediæval keep, ingeniously concealed in the thickness of a wall, or in a pillar. The most celebrated of Norman times are the White Tower in London, the castles at Rochester, Arundel, and Newcastle, Castle Hedingham, &c. The keep was often circular, as at Conisborough and Windsor.

KEY-STONE, in classic architecture, the centre voussoir of an arch, often ornamented with carving. In Pointed architecture there is often no key-stone. For those to groined arches, see BOSS.

KNOB, KNOT, the bunch of flowers carved on a Corbel, or on a Boss.

LABEL, the outer projecting moulding over doors, windows, arches, &c., sometimes called *Dripstone* or *Weather Moulding*, or *Hood-Mould*. The former terms seem scarcely applicable, as this moulding is often found inside a building where no rain could come, and consequently there is no drip. The latter term is described under HOOD-MOULD. In Norman times the label frequently did not project at all, and when it did it was very little, and formed part of the series of arch mouldings. In the Early English styles they were not very large, sometimes slightly undercut, sometimes deeply, sometimes a quarter round with chamfer, and very frequently a "roll" or "scroll moulding," so called because it resembles the part of a scroll where the edge laps over the body of the roll. Labels generally resemble the string-courses of the periods, and, in fact, often return horizontally and form strings. They are less common in Continental architecture than in English. (See DRIPSTONE, HOOD-MOULD, STRING-COURSES.)

LABEL TERMINATIONS, carvings on which the labels terminated near the springing of the windows. In Norman times these were frequently grotesque heads of fish, birds, &c., and sometimes stiff foliage, as at Shoreham. In the Early English and Decorated periods they are often elegant knots of flowers, or heads of kings, queens, bishops, and other persons supposed to be the founders of churches. In the Perpendicular period they often finished with a short, square mitred return or knee, and the foliages are generally leaves of square or octagonal form.

LACUNAR (Lat.), a panelled or coffered ceiling or soffit. The panels or cassoons of a ceiling are by Vitruvius called *lacunaria*.

LANTERN (Lat. *laterna*), a turret raised above a roof or tower, and very much pierced, the better to transmit light. In modern practice this term is generally applied to any raised part in a roof or ceiling containing vertical windows, but covered in horizontally. The name was also often applied to the *louvre* or *femerell* on a roof to carry off the smoke; sometimes, too, to the open constructions at the top of towers, as at Ely Cathedral, Boston in Lincolnshire, probably because lights were placed in them at night to serve as beacons.

LANTERNS OF THE DEAD, curious small slender towers, found chiefly in the centre and west of France, having apertures at the top, where a light was exhibited at night to mark the place of a cemetery. Some have supposed that the round towers in Ireland may have served for this purpose.

LAVABO (Fr. *lavoir*, Ital. *lavatoio*), the lavatory for washing hands, generally erected in the cloisters of monasteries. Those at Gloucester, Norwich, and Lincoln are best known. A very curious one at Fontenay, surrounding a pillar, is given by Viollet-le-Duc. In general it is a sort of trough, and in some places has an almery for towels, &c.

LICH GATE, a covered gate at the entrance of a cemetery, under the shelter of which the mourners rested with the corpse, while the procession of the clergy came to meet them. There is a very fine one at Ashwell, Herts.

LIERNE RIB, a rib crossing nearly horizontally from the ogive ribs to the tiercerons or the *arcs doubleaux*, or forming patterns in fan and stellar vaulting. (See GROINED VAULTING.)

LIP MOULD, a moulding of the Perpendicular period like a hanging lip.

LOFT, the highest room in a house, particularly if in the roof; also a gallery raised up in a church to contain the rood, the organ, or singers.

LOOP HOLE (Fr. *archière*, *meurtrière*, Ital. *feritoia*), an opening in the wall of a building, very narrow on the outside, and splayed within, from which arrows or darts might be discharged on an enemy. They are often in the form of a cross, and generally have round holes at the ends. (See OYLETS.)

LOUVRE, a lantern upon the roof of a hall for the passage of the smoke, when the fire was made on the pavement in the middle. (See FEMERELL, LANTERN.)

LUCARNE, a French term for a garret window; also used to signify the lights or small windows in spires.

LUFFERS (probably the same as Louvres), pieces of board, slate, or stone, placed slanting so as to exclude the rain, but to allow the passage of smoke, the sound of bells, &c.

LUNETTE, the French term for the circular opening in the groining of the lower stories of towers through which the bells are drawn up.

MACHICOLATION (Fr. *machicoulis*), an opening between a wall and a parapet, formed by corbelling over the latter, so that the defenders of the building might throw down darts, stones, and sometimes hot sand, melted lead, &c., upon their assailants below.

MANOR HOUSE, the residence of the suzerain or lord of the manor; in France the central tower or keep of a castle is often called the *manoir*. (See KEEP.)

MERLON, the solid part of a parapet between the embrasures of a battlement, sometimes pierced by loop-holes.

METOPE (Gr. *μετόπη*, a middle space), the square recess between the triglyphs in a Doric frieze. It is sometimes occupied by sculptures.

MEZZANINE (Ital. *mezzanino*, dim. of *mezzo*, the middle), a low story between two lofty ones. It is called by the French entresol, or inter-story.

MINSTER (Ger. *Münster*), probably a corruption of monasterium—the large church attached to any ecclesiastical fraternity. If the latter be presided over by a bishop, it is generally called a *Cathedral;* if by an abbot, an *Abbey;* if by a prior, a *Priory*.

MISERERE (Fr. *miséricorde*, Ital. *predella*), a seat in a stall of a large church made to turn up and afford support to a person in a position between sitting and standing. The under side is generally carved with some ornament, and very often with strange grotesque figures and caricatures of different persons. (See STALL.)

MITRE. A moulding returned upon itself at right angles is said to mitre. In joinery the ends of any two pieces of wood of corresponding form cut off at 45° necessarily abut upon one another so as to form a right angle, and are said to mitre.

MODILLION (Lat. *modulus*, a measure of proportion), so called because of its arrangement in regulated distances, the enriched block or horizontal bracket generally found under the cornice of the Corinthian entablature. Less ornamented, it is sometimes used in the Ionic. (See also MUTULE.)

MODULE (Lat. *modulus*, from *modus*, a measure or rule). This is a term which has been generally used by architects in determining the relative proportions of the various parts of a columnar ordinance. The semidiameter of the column at its base is the module, which being divided into thirty parts called minutes, any part of the composition is said to be of so many modules and minutes, or minutes alone, in height, breadth, or projection. The whole diameter is now generally preferred as a module, it being a better rule of proportion than its half.

MONASTERY, a set of buildings adapted for the reception of any of the various orders of monks, the different parts of which are described in the separate article ABBEY.

MONOPTEROS (Gr. *μόνος*, one, or single, and *πτερόν*, a wing). This term is used by Vitruvius to describe a temple composed of a circular range of columns supporting a tholus, cupola, or dome, but without walls. (See PERIPTEROS.) Such an edifice would be more correctly designated as Cyclostylar. (See CYCLOSTYLE.)

MONOTRIGLYPH (Gr. *μόνος*, one, or single, and TRIGLYPH, *q.v.*) The intercolumniations of the Doric order are determined by the number of triglyphs which intervene instead of the number of diameters of the column as in other cases; and this term designates the ordinary intercolumniation of one triglyph.

MONUMENT, a name given to a tomb, particularly to those fine structures recessed in the walls of mediæval churches.

MOSAIC (Lat. *opus musivum*, Ital. *musaico*, Fr. *mosaique*), pictorial representations, or ornaments formed of small pieces of stone, marble, or enamel of various colours. In Roman houses the floors are often entirely of mosaic, the pieces being cubical. There are several fine specimens in Westminster Abbey, particularly the pavement of the choir.

MOULDING (Lat. *modulus*, Ital. *modanatura*, Fr. *moulure*, Ger. *Simswerk*). When any work is wrought into long regular channels or projections, forming curves or rounds, hollows, &c., it is said to be *moulded*, and each separate member is called a *moulding*. In mediæval architecture the principal mouldings are those of the arches, doors, windows, piers, &c. The remains of Saxon work are so few, that we can tell but little about these mouldings. The arches have sometimes a simple rib on them, sometimes are chamfered, and sometimes are quite plain. Early Norman work is much the same. By degrees, however, the arrises were finished by a round or bowtell. Later, hollows and rounds together became common, and the arches were set back one behind another, each being frequently supported by a jamb-shaft or column, though very often the arch mouldings continued down the jambs without any break. In the Early English style, the mouldings, for some time, like those of the preceding period, formed groups set back in squares; they are smaller, lighter, more graceful, and frequently very deeply undercut. The *scroll* moulding is also common. Small fillets now became very frequent in the outer parts of the rounds. This has often been called the *keel* moulding, from its resemblance in section to the bottom of a ship: sometimes also it has a peculiar hollow on each side like two wings. Later in the Decorated style the mouldings are more varied in design, though hollows and rounds still prevail. The undercutting is not so deep, fillets abound, ogees are more frequent, and the *wave* mould, double ogee, or double ressaunt, is often seen. In many places the strings and labels are a round, the lower half of which is cut off by a plain chamfer. The mouldings in the later styles in some degree resemble those of the Decorated, flattened and extended; they run more into one another, having fewer fillets, and being as it were less grouped. One of the principal features of the change is the substitution of one, or perhaps two (seldom more), very large hollows in the set of mouldings. These hollows are neither circular nor elliptical, but obovate, like an egg cut across, so that one-half is larger than the other. The brace mould also has a small bead, where the two ogees meet. Another sort of moulding, which has been called a *lip mould*, is common in parapets, bases, and weatherings. For the ancient mouldings see the general article, *supra*.

MOULDINGS, ORNAMENTED. The Saxon and early Norman mouldings do not seem to have been much enriched, but the complete and later styles of Norman are remarkable for a profusion of ornamentation, the most usual of which is what is called the zig-zag. This seems to be to Norman architecture what the meander or fret was to the Grecian; but it was probably derived from the Saxons, as it is very frequently found in their pottery. Bezants, quatrefoils, lozenges, crescents, billets, beads of nails, are very common ornaments; besides these, battlements, cables, large ropes, round which smaller ropes are turned, or, as our sailors say, "wormed," scallops, pellets, chains, a sort of conical barrels, quaint stiff foliages, beaks of birds, heads of fish, ornaments of almost every conceivable kind, are sculptured in Norman mouldings; and they are used in such profusion as has been attempted in no other style. The decorations on Early English mouldings are chiefly the dog-tooth, which is one of the great characteristics of this style, though it is to be found in the Transition Norman. It is generally placed in a deep hollow between two projecting mouldings, the dark shadow in the hollow contrasting in a very beautiful way with the light in these mouldings. In this period and in the next the tympanum over doorways, particularly if they are double doors, is highly ornamented. Those of the Decorated period resemble the former, except that the foliage is more natural, and the dog-tooth gives way to the ball-flower. Some of the hollows also are ornamented with rosettes set at intervals, which are sometimes connected by a running tendril, as the ball-flowers are frequently. Some very pleasing leaf-like ornaments in the labels of windows are often found in Continental architecture. In the Perpendicular period the mouldings are ornamented very frequently by square four-leaved flowers set at intervals, but the two characteristic ornaments of the time are running patterns of vine leaves, tendrils, and grapes in the hollows, which by old writers are called "vignettes in casements," and upright stiff leaves, generally called the Tudor leaf. On the Continent mouldings partook much of the same character.

MULLION, MUNION, often corrupted into *munting*, *monyal* (Fr. *meneau*, Ital. *regolo*, Ger. *Fensterpfoste*). The perpendicular pieces of stone, sometimes like columns, sometimes like slender piers, which divide the bays or lights of windows or screen work from each other. In all styles, in less important work, the mullions are often simply plain chamfered, and more commonly have a very flat hollow on each side. In larger buildings there is often a bead or bowtell on the edge, and often a single very small column with a capital; these are more frequent in foreign work than in English. Instead of the bowtell they often finish with a sort of double ogee. As tracery grew richer, the windows were divided by a larger order of mullion, between which came a lesser or subordinate set of mullions, which ran into each other.

MUTULE (Lat. *mutulus*, a stay or bracket), the rectangular impending block under the corona of the Doric cornice, from which guttæ or drops depend. Mutule is equivalent to modillion, but the latter term is applied more particularly to enriched blocks or brackets, such as those of Ionic and Corinthian entablatures.

NAOS (Gr. ναός, a temple). This term is sometimes used instead of the Latin *cella*, as applied to the interior; strictly, however, it means the body of the edifice itself, and not merely its interior or cell.

NARTHEX (Gr. νάρθηξ, a ferula or rule), the long arcaded porch forming the entrance into the Christian basilica. Sometimes there was an inner narthex or lobby before entering the church. When this was the case, the former was called exo-narthex, and the latter eso-narthex. In the Byzantine churches this inner narthex forms part of the solid structure of the church, being marked off by a wall or row of columns, whereas in the Latin churches it was usually formed only by a wooden or other temporary screen.

NAVE (Lat. *navis*, Ital. *navata*, Fr. *nef*, Ger. *Schiff*), the central part between the arches of a church, which formerly was separated from a chancel or choir by a screen. It is so called from its fancied resemblance to a ship. In the nave were generally placed the pulpit and font. Abroad it often also contains a high altar, but this is of rare occurrence in England. Instances of this, however, are to be found at Durham and St Albans.

NECKING, the annulet or round, or series of horizontal mouldings, which separates the capital of a column from the plain part or a shaft. In Norman work they are often corded.

NEWEL (Fr. *noyau*, Ital. *albero d'una scala*, Ger. *Spindel*), in mediæval architecture, the circular ends of a winding staircase which stand over each other, and form a sort of cylindrical column.

NICHE (Fr. *niche*, Ital. *nicchia*, Gr. *Nische*), a recess sunk in a wall, generally for the reception of a statue. They sometimes are terminated by a simple label, but more commonly by a canopy, and with a bracket or corbel for the figure, in which case they are often called *tabernacles*.

OCTASTYLE (Gr. ὀκτώ, eight, and στῦλος, a column), a portico of eight columns in front.

OGEE (Lat. *cyma reversa*, Ital. *gola dritta*, *gola a rovescio*, Fr. *cimaise*, *doucine*, *gorge*, *gueule*, *gueule renversée*, *talon*, Ger. *Hohlleisten*), the name applied to a moulding, partly a hollow and partly a round, and derived no doubt from its resemblance to an *O* placed over a *G*. It is rarely found in Norman work, and is not very common in Early English. It is of frequent use in the Decorated, where it becomes sometimes double, and is called a *wave* moulding; and later still, two waves are connected with a small bead, which is then called a *brace* moulding. In ancient MSS. it is called a RESSAUNT, *q.v.*

OGIVE, a term applied by the French to the pointed arch. OGIVE RIB, the main ribs which cross each other on the intersection of the vaulting. (See GROINED VAULTING.)

ORATORY (Fr. *oratoire*), a small chapel or place for prayer for the use of private individuals, generally attached to a mansion, and sometimes to a church. The name is also given to small chapels built to commemorate some special deliverance.

ORDER. A column with its entablature and stylobate is so called. The term is the result of the dogmatic laws deduced from the writings of Vitruvius, and has been exclusively applied to those arrangements which they were thought to warrant. For the different details of an order, see Plate XXIV., fig. 1.

ORDER, the name given to the subordinate mullions and tracery which are of smaller size than others in the same window, &c. It is also applied to the groups of mouldings arranged on square faces set back behind one another in Norman and Early English work, and not cut in on the splayed faces of the jambs and arch moulds as in subsequent periods.

ORDINANCE, a composition of some particular order or style. It need not be restricted to a columnar composition, but applies to any species which is subjected to conventional rules for its arrangement.

ORIEL or ORYEL. See BAY WINDOW.

ORTHOGRAPHY (Gr. ὀρθός, straight or true, and γραφή, a description or representation), a geometrical elevation of a building or other object, in which it is represented as it actually exists or may exist, and not perspectively, or as it would appear.

ORTHOSTYLE (Gr. ὀρθός, straight or true, and στῦλος, a column), any straight range of columns. This is a term suggested to designate what is generally but improperly called a PERISTYLE, *q.v.*, that is, columns in a straight row or range, but not forming a portico.

OSSUAIRE. See CHARNEL HOUSE.

OVOLO (from the Ital., meaning egg-formed), the name most commonly applied to the moulding which appears to have originated in the moulded head of the Doric column, and which, with an abacus, formed its capital.

OYLEMENTS, a word used in the Beauchamp Roll, signifying the small quatrefoil lights in the head of a Perpendicular window.

OYLETS, or OIELLETS, a name sometimes applied to the arrow-slits in towers, &c.; but it seems more probable its strict meaning is the round hole or circle with which these terminate.

PACE, the landing on a broad step in a stair; also any stage raised above the floor.

PAN or PANE. See POST AND PANE WORK.

PANE, probably a diminutive of *panneau*, a term applied to a bay of a window, compartment of a partition, side of a tower, turret, &c. (See BAY.)

PANEL (Fr. *panneau*, Ital. *quadretto*, *formello*, Ger *Feld*), properly the piece of wood framed within the styles and rails of a door, filling up the aperture, but often applied both to the whole square frame and the sinking itself; also to the ranges of sunken compartments in cornices, corbel tables, groined vaults, ceilings, &c. In Norman work these recesses are generally shallow, and more of the nature of *arcades*. In Early English work the square panels are ornamented with quatrefoils, cusped circles, &c., and the larger panels are often deeply recessed, and form niches with trefoil heads and sometimes canopies. In the Decorated style the cusping and other enrichments of panels become more elaborate, and they are often filled with shields, foliages, and sometimes figures. Towards the end of this period the walls of important buildings were often entirely covered with long or square panels, the former frequently forming niches with statues. The use of panels in this way became very common in Perpendicular work, the wall frequently being entirely covered with long, short, and square panels, which latter are frequently richly cusped, and filled with every species of ornament, as shields, bosses of foliage, portcullis, lilies, Tudor roses, &c. Wooden panellings very much resembled those of stone, except in the Tudor period, when the panels were enriched by a varied design, imitating the plaits of a piece of linen or a napkin folded in a great number of parallel lines. This is generally called the *linen pattern*. Wooden ceilings, which are very common, are composed of thin oak boards nailed to the rafters, collars, &c., and divided into panels by oak mouldings fixed on them, with carved bosses at the intersections.

PARADISE, PARVISE, PARVYCE, a word of uncertain origin, but supposed to be a corruption of *paradisus*, an enclosed garden. Paradises were open places surrounded with an enceinte or stone parapet in front of cathedrals or other great buildings, and probably were used to keep the people from pressing on and confusing the marshalling of the public processions. That at Nôtre Dame, at Paris, is of irregular shape; that at Amiens was round. Nothing of the kind is left in England, though, from a passage in Chaucer, it is supposed there was one in the front of Westminster Hall. The *Promptorium Parvulorum* calls a parvise *parlatorium*, a place for conversation. The small chambers over porches have also been named parvises. The irregularly-shaped cloister at Chichester is still called a paradise.

PARAPET (from the Italian *parapetto*, something which comes against the breast, *i.e.*, to lean against, Fr. *parapet*, Ger. *Brustwehre*), a dwarf wall along the edge of a roof, or round a lead flat, terrace walk, &c., to prevent persons from falling over, and as a protection to the defenders in case of a siege. Parapets are either plain, embattled, perforated, or panelled. The last two are found in all styles except the Norman. Plain parapets are simply portions of the wall generally overhanging a little, with a *coping* at the top and *corbel* table below. Embattled parapets are sometimes panelled, but oftener pierced for the discharge of arrows, &c. Perforated parapets are pierced in various devices—as circles, trefoils, quatrefoils, and other designs—so that the light is seen through. Panelled parapets are those ornamented by a series of panels, either oblong or square, and more or less enriched, but are not perforated. These are common in the Decorated and Perpendicular periods.

PARASCENIUM, in a Greek theatre, the wall at the back of the stage.

PARASTAS (Gr. παραστάς, standing before), an end pilaster, the Greek term for which the Latin *antæ* is generally used. (See ANTÆ.)

PARCLOSE, a word used for any enclosure to a chantry, tomb, &c.

PAREMENT, a French term for the outside ashlar or casing of a rubble wall, which is tied together by through or bond stones. (See PERPENT.)

PARGETTING, a species of plastering decorated by impressing patterns on it when wet. These seem generally to have been made by sticking a number of pins in a board in certain lines or curves, and then pressing on the wet plaster in various directions, so as to form geometrical figures. Sometimes these devices are in relief, and in the time of Elizabeth represent figures, birds, foliages, &c.; fine examples are to be seen at Ipswich, Maidstone, Newark, &c. The word (which is Latinised *gypsacio* in the *Promptorium*) may be derived from the old French *géter*, to cast, to throw, as outside plastering is often thrown against the laths to make it adhere better. (See ROUGH CAST.)

PARVISE. See PARADISE.

PATIN, PATAND, from the French *patin*, a wooden sole, clog, or patten. The sills in timber-framing are thus named in some old works, though modern French authors call them *sablières*.

PEDESTAL. An insulated stylobate is for the most part so called. The term is, moreover, generally applied to any parallelogramic or cylindrical mass, used as the stand or support of any single object, as a statue or vase.

PEDIMENT, that part of a portico which rises above its entablature to inclose the end of the roof, whose triangular form it takes. The cornice of the entablature, or its corona, and part of the bed-mould only, with the addition of a cymatium, bounds its inclined sides, and gives it an obtuse angle at the apex. In Pointed architecture, however, the angle of a pediment is for the most part acute.

PENDENT, a name given to an elongated boss, either moulded or foliated, such as hang down from the intersection of groins, specially in fan tracery, or at the end of hammer beams. Sometimes long corbels, under the wall pieces, have been so called. The name has also been given to the large masses depending from enriched ceilings, in the later works of the Pointed style.

PENDENT POSTS, a name given to those timbers which hang down the side of a wall from the plate, and which receive the hammer braces.

PENDENTIVE, a name given to an arch which cuts off, as it were, the corners of a square building internally, so that the superstructure may become an octagon or a dome. In mediæval architecture these arches, when under a spire in the interior of a tower, are called SQUINCHES (which see).

PERIBOLUS (Gr. περί, around or about, and βάλλω, to throw), an inclosure. Any inclosed space is a peribolus; but the term is applied more particularly to the sacred enclosure about a temple. The wall forming the enclosure is also called the peribolus.

PERIPTEROS (Gr. περί, around or about, and πτερόν, a wing), a temple or other structure with the columns of its end prostyles, or porticoes, returned on its sides as wings at the distance of one intercolumniation from the walls. Almost all the Doric temples of the Greeks were peripteral. The term is applied by Vitruvius to peristylar structures.

PERISTYLE (Gr. περί, around or about, and στῦλος, a column), a range of columns encircling an edifice, such as that which surrounds the cylindrical drum under the cupola of St Paul's. The columns of a Greek peripteral temple form a peristyle also, the former being a circular, and the latter a quadrilateral peristyle.

PERPENT STONES (Fr. *parpaing*), bond or "through stones," the διατόνοι of the Greeks and Romans. Long stones going right through walls, and tying them together from face to face.

PERRON, the grand flight of external steps entering the mansions of the mediæval nobility or high officials, and considered in itself as a mark of jurisdiction, as it is said that sentence was there pronounced against criminals, who were afterwards executed at the foot of the steps—as at the Giant Stairs at Venice. One of the finest later examples is the flight in the Horse-shoe Court at Fontainebleau.

PEWS (Lat. and Gr. *podium*; comp. Fr. *pui*), fixed seats in churches, composed of wood framing, mostly with ornamented ends. They seem to have come into general use early in the reign of Henry VI., and to have been rented and "well payed for" (see Bale's *Image of Both Churches*) before the Reformation. Some bench ends are certainly of Decorated character, and some have been considered to be of the Early English period. They are sometimes of plain oak board, 2½ to 3 inches thick, chamfered, and with a necking and finial generally called a *poppy head;* others are plainly panelled with bold cappings; in others the panels are ornamented with tracery or with the *linen pattern*, and sometimes with running foliages. The divisions are filled in with thin chamfered boarding, sometimes reaching to the floor, and sometimes only from the capping to the seat.

PIERS, the solid parts of a wall between windows and between voids generally. The term is also applied to masses of brickwork or masonry which are insulated to form supports to gates or to carry arches.

PIGNON, a French term for the gable of a roof. (See GABLE.)

PILASTER (from Lat. *pila*, a pillar), an inferior sort of column or pillar; a projection from or against a pier, with the form and decorations of antæ, but frequently (always in Roman examples) having capitals, like those of columns, assigned them.

PILLAR, or PYLLER (Fr. *pilier*, Ital. *pilastro, colonna*, Ger. *Pfeiler*), a word generally used to express the round or polygonal piers or those surrounded with clustered columns, which carry the main arches of a building. Saxon and early Norman pillars are generally stout cylindrical shafts built up of small stones. Sometimes, however, they are quite square, sometimes with other squares breaking out of them (this is more common on the Continent), sometimes with angular shafts, and sometimes they are plain octagons. In Romanesque Norman work the pillar is sometimes square, with two or more semicircular or half columns attached. In the Early English period the pillars become loftier and lighter, and in most important buildings are a series of clustered columns, frequently of marble, placed side by side, sometimes set at intervals round a circular centre, and sometimes almost touching each other. These shafts are often wholly detached from the central pillar, though grouped round it, in which case they are almost always of Purbeck or Bethersden marbles. In Decorated work the shafts on plan are very often placed round a square set angle-wise, or a lozenge, the long way down the nave; the centre or core itself is often worked into hollows or other mouldings, to show between the shafts, and to form part of the composition. In this and the latter part of the previous style there is generally a fillet on the outer part of the shaft, forming what has been called a keel moulding. They are also often as it were tied together by bands formed of rings of stone and sometimes of metal. About this period, too, these intermediate mouldings run up into and form part of the arch moulds, the impost not being continuous; or rather there is no impost, but the shafts have each their own separate cap. (See IMPOST.) This arrangement became much more frequent in the Perpendicular period; in fact it was almost universal, the commonest section being a lozenge set with the long side from the nave to the aisle, and not towards the other arches, as in the Decorated period, with four shafts at the angles, between which were shallow mouldings, one of which in general was a wide hollow, sometimes with wave moulds. As the pillar altogether by the arrangement was wider than the wall above, the shafts facing the nave ran up to the roof, and served in place of the vaulting shafts of the previous periods. The small pillars at the jambs of doors and windows, and in arcades, and also those slender columns attached to pillars, or standing detached, are generally called SHAFTS (which see.)

PILLOWED. A swollen or rounded frieze is said to be pillowed or pulvinated.

PINNACLE (Fr. *pinacle, finoison*, Ital. *pinacolo*,—literally a little feather—Ger. *Pinnakyl*), an ornament originally forming the cap or crown of a buttress or small turret, but afterwards used on parapets at the corners of towers and in many other situations. Some writers have stated there were no Norman pinnacles; but ... caps to circular buttresses, with a sort of finial, are not uncommon in France at very early periods. Viollet-le-Duc gives examples from St Germer and St Remi, and there is one of similar form at the west front of Rochester Cathedral. In the later Norman period, two examples have been cited, one from Bredon in Worcestershire, and the other from Cleeve in Gloucestershire. In these the buttresses run up, forming a sort of square turret, and crowned with a pyramidal cap, very much like those of the next period, the Early English. In this and the following styles the pinnacle seems generally to have had its appropriate uses. It was a weight to counteract the thrust of the groining of roofs, particularly where there were flying buttresses; it stopped the tendency to slip of the stone copings of the gables, and counterpoised the thrust of spires; it formed the piers to steady the elegant perforated parapets of later periods; and in France especially served to counterbalance the weight of overhanging corbel tables, huge gargoyles, &c. In the Early English period the smaller buttresses frequently finished with GABLETS (which see), and the more important with pinnacles supported with clustered shafts. At this period the pinnacles were often supported on these shafts alone, and were open below; and in larger work in this and the subsequent periods they frequently form niches and contain statues. About the Transition and during the Decorated period, the different faces above the angle shafts often finish with gablets. Those of the last-named period are much richer, and are generally decorated with crockets and finials, and sometimes with ball-flowers. Very fine groups are found at Beverley Minster and at the rise of the spire of St Mary's, Oxford. Perpendicular pinnacles differ but little from Decorated, except that the crockets and finials are of later character. They are also often set angle-ways, particularly on parapets, and the shafts are panelled. In France, pinnacles, like spires, seem to have been in use earlier than in England. There are small pinnacles at the angles of the tower in the Abbey of Saintes. At Roullet there are pinnacles in a similar position, each composed of four small shafts, with caps and bases surmounted with small pyramidal spires. In all these examples the towers have semicircular headed windows.

PISCINÆ, one or more hollows or *cuvettes* near the altars, with drains to take away the water used in the ablutions at the mass. They seem at first to have been mere cups or small basins, supported on perforated stems, placed close to the wall, and afterwards to have been recessed therein and covered with niche heads, which often contained shelves to serve as aumbries. They are rare in England till the 13th century, after which there is scarcely an altar without one. They frequently take the form of a double niche, with a shaft between the arched heads, which are often filled with elaborate tracing.

PITCH OF A ROOF, the proportion of the height of a roof to its span. (See GABLE.)

PLAN, a horizontal geometrical section of the walls of a building; or indications, on a horizontal plane, of the relative positions of the walls and partitions, with the various openings, such as windows and doors, recesses and projections, chimneys and chimney-breasts, columns, pilasters, &c. This term is often incorrectly used in the sense of DESIGN, *q.v.*

PLANCEER is sometimes used in the same sense as soffit, but is more correctly applied to the soffit of the corona in a cornice.

PLASTERING (Fr. *plâtre*, Ital. *intonaco*, Ger. *Putzarbeit*), a mixture of lime, hair, and sand, to cover lath-work between timbers or rough walling, used from the earliest times, and very common in Roman work. In the Middle Ages, too, it was used not only in private but in public constructions. On the inside face of old rubble walls it was not only used for purposes of cleanliness, rough work holding dirt and dust, but as a ground for distemper painting (*tempera*, or, as it is often improperly called, *fresco*), a species of ornament often used in the Middle Ages. At St Alban's Abbey the Norman work is plastered and covered with lines imitating the joints of stone. The same thing is found in the Perpendicular work at Ash in Kent. On the outside of the like walls, and often of wood-framing, it was used as *rough cast;* when ornamented in patterns outside, it is called *pargetting*.

PLINTH (Gr. πλίνθος, a square tile). In the Roman orders the lowest member of the base of a column is square and vertically faced; this is called a plinth.

PODIUM, strictly something upon or against which the foot may be placed; and in this sense, probably, it was applied to the wall which bounds the arena of an amphitheatre, and is thereby at the feet of the most advanced of the spectators.

POLYTRIGLYPH, an intercolumniation in the Doric order of more than two triglyphs. (See MONOTRIGLYPH, DITRIGLYPH, and TRIGLYPH.)

POMMEL, a name given to any round knob, as a boss, a finial, &c.

POPPY HEADS, probably from the French *poupée*, the finials or other ornaments which terminate the tops of bench ends, either to pews or stalls. They are sometimes small human heads, sometimes richly carved images, knots of foliages, or finials, and sometimes *fleurs-de-lis* simply cut out of the thickness of the bench end and chamfered.

PORCH (Gr. νάρθηξ, Lat. *porticus*, Fr. *porche*, Ital. *portico*, Ger. *Vorhalle*), a covered erection forming a shelter to the entrance door of a large building. The earliest known are the long arcaded porches in front of the early Christian basilicas, called NARTHEX (which see). In later times they assume two forms—one the projecting erection covering the entrance at the west front of cathedrals, and divided into three or more doorways, &c., and the other a kind of covered chambers open at the ends, and having small windows at the sides as a protection from rain. These generally stand on the north or south sides of churches, though in Kent there are a few instances (as Snodland and Boxley) where they are at the west ends. Porches are of very early use. Those of the Norman period generally have but little projection, and are sometimes so flat as to be but little more than outer dressings and hood-moulds to the inner door. They are, however, often very richly ornamented, and, as at Southwell in England and Kelso in Scotland, have rooms over, which have been erroneously called *parvises*. (See PARADISE.) Early English porches are much longer, or project much further from the faces of the churches to which they are attached, and in larger and more important buildings have very frequently rooms above; the gables are generally bold and high pitched. In larger buildings also, as at Wells, St Albans, &c., the interiors are very rich in design, quite as much so, in fact, as the exteriors. Decorated and Perpendicular porches partake of much the same characteristics, the pitch of roof, mouldings, copings, battlements, &c., being of course influenced by the taste of the time. As a general rule, however, the later porches had rooms over them more frequently than in earlier times; these are often approached from the lower story by small winding stairs, and sometimes have fire-places, and are supposed to have served as vestries; and sometimes there are the remains of a piscina, and relics of altars, as if they had been used as chantry chapels. It is probable there were wooden porches at all periods, particularly in those places where stone was scarce; but, as may be expected from their exposed position, the earliest have decayed. At Cobham, Surrey, there was one that had ranges of semicircular arches in oak at the sides, of strong Norman character, which is now unfortunately destroyed. It is said there are several in which portions of Early English work still are traceable, as at Chevington, in Suffolk. In the Decorated and later periods, however, wooden porches are very common, some plain, and others with richly carved tracery and barge boards; these frequently stand on a sort of half story of stone work or *bahut*. The entrance porches at the west end of our cathedrals are generally called *portals*, and where they assume the character of separate buildings, are designated *galilees*. Both these are more common on the Continent than in England. Many of the French cathedrals have the doors so deeply recessed as to be almost like open porches. These are called *portails* or *portes abrités*. Many, however, have detached porches in front of the portals themselves. The noblest example of an open projecting western porch in England, and probably in the world, is at Peterborough, of the Early English period, attached to the Early Norman nave.

PORTAL (Fr. *portail*, Ital. *portone*), a name given to the deeply recessed and richly decorated entrance doors to the cathedrals on the Continent.

PORTCULLIS (M. Lat. *cataracta*, Fr. *herse*, *coulisse*, Ital. *saracinesca*, Ger. *Fallgatter*), a strong-framed grating of oak, the lower points shod with iron, and sometimes entirely made of metal, hung so as to slide up and down in grooves with counterbalances, and intended to protect the gateways of castles, &c. The defenders having opened the gates and lowered the portcullis, could send arrows and darts through the gratings, and yet the assailants could not enter. One of these constructions was in existence until modern times in a gateway at York; they are said not to be older than the 12th century, and were probably (as their Italian name imports) invented as a defence against the sudden attacks of the Saracens on the coasts of that country.

PORTICO (an Italicism of the Lat. *porticus*), an open space before the door or other entrance to any building fronted with columns. A portico is distinguished as prostyle or *in antis* according as it projects from or recedes within the building, and is further designated by the number of columns its front may consist of. (See DISTYLE, TETRASTYLE, HEXASTYLE, OCTASTYLE, &c.)

PORTICUS. In an amphiprostylar or peripteral temple this term is used to distinguish the portico at the entrance from that behind, which is called the posticum.

POST AND PANE WORK, a name given to the carpentry framing of old wooden houses, *panne* in old French signifying any horizontal piece of timber, as a head, sill, or purlin, though its use now is confined to the latter, sills and plates at present being called *sablières*. Where timber was abundant, and stone scarce and dear to work, timber-framed houses naturally abounded. The posts or uprights seem in early times to have been constructed of small oak trees, 6 or 7 inches square, roughly trimmed by the axe; the girders, &c., are larger, but seldom seem to have been sawn. The framing of the lower story generally stands on a sort of plinth or *bahut* of stone or brick, sometimes as high as the window sills, and the other fronts are each framed separately; and as the joists of each story project over those of that below, each story also projects, till, in narrow streets, it is said the houses almost touched each other at the top. To strengthen the framing, it was customary to tie the angles together with circular braces cut out of the crooked boughs of trees, and to fill in under and sometimes over the window openings with cross struts, sometimes like the St Andrew's cross, and sometimes in circles and various designs. The main posts also were strengthened inside and out with a sort of projecting corbels, called in French *liens* or *décharges*, and by us *spervers*, which helped to carry the projecting plates above. In the better sort of work these timbers are chamfered and sometimes carved, and the gables have rich barge boards; the roofs invariably have great projections to throw off the wet, and the jutting of the stories, one over the other, no doubt was intended for the same purpose. Old post and pane work is put together with mortices and tenons pinned with pins or trunnels of hard wood; very often there is not a nail in the whole construction. The intermediate upright posts or quarters were called *prick posts*. All these houses are plastered, rough cast, or pargetted between the timbers, sometimes in handsome designs, and as the old oak gets black with age, or as the timbers are often rubbed over with oil, and the plaster whited, they are called in England *black and white houses*. (See PARGETTING and PLASTERING.) Several churches in Essex have post and pane work.

POSTERN, a small gateway in the enceinte of a castle, abbey, &c., from which to issue and enter unobserved. They are often called *Sally Ports*

POSTICUM (Lat.) A portico behind a temple. (See POSTICUS and PORTICO.)

PRECEPTORY, a small establishment of the Knights Templars, managed by a preceptor, a subordinate officer to a master, in the same way as a priory was by a prior, and not an abbot.

PRESBYTERY (Lat. *presbyterium*, Ital. *presbiterio*, Fr. *presbytère*), a word applied to various parts of large churches in a very ambiguous way Some consider it to be the choir itself; others, what is now named the *sacrarium*. Traditionally, however, it seems to be applied to the vacant space between the back of the high altar and the entrance to the lady chapel, as at Lincoln and Chichester; in other words, the *Back* or *Retro Choir*.

PRICK POSTS, an old name given sometimes to the queen posts of a roof, and sometimes to the filling in quarters in framing. (See POST and PANE.)

PRIORY, a monastic establishment, generally in connection with an abbey, and presided over by a prior, who was a subordinate to the abbot, and held much the same relation to that dignitary as a dean does to a bishop. (See ABBEY.)

PROCESSION PATH (Lat *ambitus templi*), the route taken by processions on solemn days in large churches—up the north aisle, round behind the high altar, down the south aisle, and then up the centre of the nave.

PRONAOS (Gr. πρό, before, and ναός, a temple), the inner portico of a temple, or the space between the porticus, or outer portico, and the door opening into the cella. This is a conventional use of the term; for, strictly, the pronaos is the portico itself.

PROPYLÆUM (Gr. πρό, before, and πύλη, a portal), any structure or structures forming the entrance to the peribolus of a temple; also the space lying between the entrance and the temple. In common usage this term in the plural (propylæa) is almost restricted to the entrance to the Acropolis of Athens, which is known by it as a name. The form *propylon* occurs in the Latin of Vitruvius.

PROSCENIUM, the stage in ancient theatres.

PROSTYLE (Gr. πρό, before, and στῦλος, a column), a portico in which the columns project from the building to which it is attached.

PSEUDO-DIPTERAL (Gr. ψευδής, false, and DIPTEROS, *q.v.*), false double-winged. When the inner row of columns of a dipteral arrangement is omitted and the space from the wall of the building to the columns is preserved, it is pseudo-dipteral The portico of University College, London, is pseudo-dipterally arranged, the returning columns on the ends or sides not being carried through behind those in front.

PSEUDO-PERIPTERAL (Gr. ψευδής, false, and PERIPTEROS, *q.v.*), false-winged. A temple having the columns on its flanks attached to the walls, instead of being arranged as in a peripteros, is said to be a pseudo-peripteral.

PULPIT (Fr. *chaire de l'église*, Ital. *pulpito*, Ger. *Kanzel*), a raised platform with enclosed front, whence sermons, homilies, &c., were delivered. Pulpits were probably derived in their modern form from the *ambones* in the early Christian church. There are many old pulpits of stone, though the majority are of wood. Those in churches are generally hexagonal or octagonal; and some stand on stone bases, and others on slender wooden stems, like columns. The designs vary according to the periods in which they were erected, having panelling, tracery, cuspings, crockets, and other ornaments then in use. Some are extremely rich, and ornamented with colour and gilding. A few also have fine canopies or sounding-boards. Their usual place is in the nave, mostly on the north side, against the second pier from the chancel arch. Pulpits for addressing the people in the open air were common in the mediæval period, and stood near a road or cross. Thus there was one at Spital Fields, and one at St Paul's, London. External pulpits still remain at Magdalene College, Oxford, and at Shrewsbury. Pulpits, or rather places for reading during the meals of the monks, are found in the refectories at Chester, Beaulieu, Shrewsbury, &c., in England; and at St Martin des Champs, St Germain des Prés, &c., in France; also in the cloisters at St Dié and St Lo. Shortly after the Reformation the canons ordered pulpits to be erected in all churches where there were none before. It is supposed that to this circumstance we owe so many of the time of Elizabeth and James. Many of them are very beautifully and elaborately carved, and are evidently of Flemish workmanship. The pulpits in the Mahometan mosques are quite different in form, being usually canopied and approached by a straight flight of steps. These have a doorway at the foot, with an architrave, and boldly moulded head; the whole of the work to this and to the stairs, parapet, and pulpit itself being of wood, richly inlaid, and often in part gorgeously painted and gilt.

PULVINATED (Lat. *pulvinus*, a cushion or bolster), a term used to express the swelling or bolstering of the frieze which is found in some of the inferior works of the Roman school, and is common in Italian practice. It is used indifferently with *pillowed*.

PYCNOSTYLE (Gr. πυκνός, dense, and στῦλος, a column), having columns thickly set. The space or intercolumniation implied by this term is one diameter and a half. (See EUSTYLE.)

QUARREL, QUARRY (from the French *carré*, square), any square-shaped opening; applied in the Beauchamp Roll to the quatrefoils in Perpendicular windows, sometimes to squares of paving, but most commonly to the lozenge-shaped pieces of glass in lead casements.

QUARTERS, the main upright posts in framing, sometimes called studs; the filling in quarters were formerly named prick posts.

QUATREFOIL, any small panel or perforation in the form of a four-leaved flower. They are sometimes used alone, sometimes in circles, and over the aisle windows, but more frequently they are in square panels. They are generally cusped, and the cusps are often feathered. (See CINQUEFOIL.)

QUOINS, large squared stones at the angles of buildings, buttresses, &c., generally used to stop the rubble or rough stone work, and that the angles might be true and stronger. Saxon quoin stones are said to have been composed of one long and one short stone alternately. Early quoins are generally roughly axed; in later times they had a draft tooled by the chisel round the outside edges, and later still were worked fine from the saw.

RAG-STONE, a name given by some writers to work done with stones which are quarried in thin pieces, such as the Horsham sandstone, Yorkshire stone, the slate stones, &c.; but this is more properly flag or slab work. By rag-stone, near London, is meant an excellent material from the neighbourhood of Maidstone. It is a very hard limestone of bluish-grey colour, and peculiarly suited for mediæval work. It is often laid as uncoursed work, or random work, sometimes as random coursed work, and sometimes as regular ashlar. The first method, however, is the more picturesque.

RANDOM WORK, a term used by the rag-stone masons for stones fitted together at random without any attempt at laying them in courses. *Random Coursed Work* is a like term applied to work coursed in horizontal beds, but the stones are of any height, and fitted to one another.

REAR VAULT, a name sometimes applied to the inner hood-mould of a window or doorway, but no ancient authority for the use of such a term has been cited.

REFECTORY, the hall of a monastery, convent, &c., where the religious took their chief meals together. It much resembled the great halls of mansions, castles, &c., except that there frequently was a sort of ambo, approached by steps, from which to read the legenda sanctorum, &c., during meals. (See PULPIT.)

REGULA (Lat.), a rule or square, the short fillet or rectangular block, under the tænia, on the architrave of the Doric entablature.

REREDOS, DORSAL, or DOSSEL (Fr., *retable*), the screen or other ornamental work at the back of an altar. In some large cathedrals, as Winchester, Durham, St Albans, &c., this is a mass of splendid tabernacle work, reaching nearly to the groining. In smaller churches there are sometimes ranges of arcades or panellings behind the altars; but, in general, the walls at the back and sides of them were of plain masonry, and adorned with hangings or paraments. In large churches abroad, the high altar usually stands under a sort of canopy or ciborium, and the sacrarium is hung round at the back and sides with curtains on movable rods. (See CIBORIUM.) In private houses the iron plates behind the fire, where there are andirons, are sometimes called *reredoses*.

RESPOND, the half pier or pillar at the end of a range of piers and arches, or other arcades; they are generally exactly half the other piers, with a short piece of wall finishing at right angles to the end or cross wall.

RESSAUNT, a sort of flat ogee. A *ressaunt lorymer* (or *larmier*) is supposed to be an ogee with a drip.

RETRO CHOIR. (See BACK CHOIR, PRESBYTERY.)

RIB (Fr. *nerf d'arête*, *nervure*, Ital. *costola*, Ger. *Rippe*). (See GROIN RIB, and also GROINED VAULTING.) The earliest groining had no ribs. In early Norman times plain flat arches crossed each other, forming *Ogive Ribs*. These by degrees became narrower, had greater projection, and were chamfered. In later Norman work the ribs were often formed of a large roll placed upon the flat band, and then of two rolls side by side, with a smaller roll or a fillet between them, much like the lower member. Sometimes they are enriched with zigzags and other Norman decorations, and about this time bosses became of very general use. (See BOSS.) As styles progressed, the mouldings were more undercut, richer and more elaborate, and had the dog-tooth or ball-flower or other characteristic ornament in the hollows. In all instances the mouldings are of similar contours to those of arches, &c., of the respective periods. (See MOULDINGS.) In Perpendicular work the ribs are broader and shallower, and almost always have two great hollows of elliptic shape, one on each side. In those churches of the Early English and Decorated periods where there is a groining of wooden ribs filled in between the spandrils with their narrow oak boards, these ribs resemble those of stone, but are slighter, and the mouldings not so bold. (See CEILING.) Later, wooden roofs are often formed into cants or polygonal barrel vaults, and in these the ribs are generally a cluster of rounds, and form square or stellar panels, with carved bosses or shields at the intersections.

RIDGE (Fr. *faîte*, *faîtage*, Ital., *comignolo*, Ger. *Rücken*), a flat piece of board running from the apex of principal to principal, to which the heads of the common rafters are nailed; also the lead or tile covering to the same. (For ornamental ridges, see CRESTING.)

ROLL MOULDING or SCROLL MOULDING, a moulding so called because it resembles the section of half a scroll or flexible book rolled up so that the edge projects over the other part. (See LABEL.)

ROOD, a name applied to a crucifix, particularly to those which were placed in the rood-loft or chancel screens. These generally had not only the image of the crucified Saviour, but also those of St John and the Virgin Mary, standing one on each side. Sometimes other saints and angels are by them, and the top of the screen is set with candlesticks or other decorations.

ROOD-LOFT, ROOD-SCREEN, ROOD-BEAM, JUBE GALLERY, &c., the arrangement to carry the crucifix or rood, and to screen off the chancel from the rest of the church during the breviary services, and as a place whence to read certain parts of those services. (See JUBE.) Sometimes the crucifix is carried simply on a strong transverse beam, with or without a low screen, with folding-doors below but forming no part of such support. The general construction of wooden screens is close panelling beneath, about 3 feet to 3 feet 6 inches high, on which stands screen work composed of slender turned balusters or regular wooden mullions, supporting tracery more or less rich with cornices, crestings, &c., and often painted in brilliant colours, and gilded. These not only enclose the chancels, but also chapels, chantries, and sometimes even tombs. In mansions, and some private houses, the great halls were screened off by a low passage at the end opposite to the dais, over which was a gallery for the use of minstrels or spectators. These screens were sometimes close and sometimes *glazed*. There are many of these in England, generally more or less mutilated: one of the most perfect galleries is that at Charlton-on-Otmoor, in Oxfordshire.

ROOD-STAIR, a small winding stair or vice leading to the gallery. (See ROOD-LOFT.) In England they generally run up in a small turret in the wall at the west end of the chancel. This also often leads out on the roof. On the Continent these stairs often lead out of the interior of churches, and are enclosed with exquisitely perforated tracery, as at Rouen, Strasbourg, &c.

ROOD-TOWER, a name given by some writers to the central tower, or that over the intersection of the nave and chancel with the transepts.

ROSE WINDOW (Fr. *rosace*), a name given to a circular window with radiating tracery, called also *wheel window*.

ROUGH CAST, a sort of external plastering in which small sharp stones are mixed, and which, when wet, is forcibly thrown or *cast* from a trowel against the wall, to which it forms a coating of pleasing appearance. Some of the rough cast at St Albans is supposed to be coeval with the building itself. This material was also much used in timber houses, and when well executed the work is sound and durable.

ROVING, anything following the line of a curve; thus the bowtell or torus going up the side of a bench end and round a finial is called a roving bowtell. (See BOWTELL.)

RUBBLE WORK, a name applied to several species of masonry. One kind, where the stones are loosely thrown together in a wall between boards, and grouted with mortar almost like concrete, is called in Italian *muraglia di getto*, and in French *blocage*. Work executed with large stones put together without any attempt at courses, or random work, is also called rubble.

SACRISTY (Lat. *sacrarium*, Fr. *sacristie*, Ital. *sagrestia*), a small chamber attached to churches, where the chalices, vestments, books, &c., were kept by the officer called the sacristan. In the early Christian basilicas there were two semicircular recesses or apsides, one on each side of the altar. One of these served as a sacristy, and the other as the bibliotheca or library. Some have supposed the sacristy to have been the place where the vestments were kept, and the vestry that where the priests put them on; but we find from Durandus that the *sacrarium* was used for both these purposes. Sometimes the place where the altar stands enclosed by the rails has been called *sacrarium*.

SADDLE BARS (Fr. *traverses*), narrow horizontal iron bars passing from mullion to mullion, and often through the whole window from side to side, to steady the stone work, and to form stays, to which the lead work is secured. When the bays of the windows are wide, the lead lights are further strengthened by upright bars, passing through eyes forged on the saddle bars, and called *stanchions* (see STANCHION and ARMATURE). When saddle bars pass right through the mullions in one piece, and are secured to the jambs, they have sometimes been called *stay bars*.

SANCTUS BELL-COT or TURRET, a turret or enclosure to hold the small bell sounded at various parts of the service, particularly where the words "Sanctus," &c., are read. This differs but little from the common bell-cot, except that it is generally on the top of the arch dividing the nave from the chancel. At Cleeve, however, the bell seems to have been placed in a cot outside the wall. Sanctus bells have also been placed over the gables of porches. On the Continent they run up into a sort of small slender spire, called *flèche* in France, and *guglio* in Italy. (See BELL-COT.)

SCAPPLING, reducing a stone to a rough square by the axe or hammer; in Kent, the rag-stone masons call this knobbling.

SCOTIA (Gr. σκοτία, shadow or darkness), a concave moulding most commonly used in bases, which projects a deep shadow on itself, and is thereby a most effective moulding under the eye, as in a base. It is like a reversed ovolo, or rather what the mould of an ovolo would present.

SCREEN, any construction subdividing one part of a building from another—as a choir, chantry, chapel, &c. The earliest screens are the low marble *podia*, shutting off the *chorus cantantium* in the Roman basilicas, and the perforated *cancelli* enclosing the bema, altar, and seats of the bishops and presbyters. The chief screens in a church are those which enclose the choir or the place where the breviary services are recited. This is done on the Continent, not only by doors and screen work, but also, when these are of open work, by curtains, the laity having no part in these services. In England screens were of two kinds, one of open wood work, generally called *rood-screens* or *jubes* (which see), and which the French call *grilles*, *clôtures du chœur*; the other, massive enclosures of stone work enriched with niches, tabernacles, canopies, pinnacles, statues, crestings, &c., as at Canterbury, York, Gloucester, and many other places both in England and abroad.

SCROLL, synonymous with VOLUTE, *q.v.*, but commonly applied to ordinary purposes, whilst volute is generally restricted to the scrolls of the Ionic capital.

SCUTCHEON. (See ESCUTCHEON.)

SECTION, a drawing showing the internal heights of the various parts of a building. It supposes the building to be cut through entirely, so as to exhibit the walls, the heights of the internal doors and other apertures, the heights of the stories, thicknesses of the floors, &c. It is one of the species of drawings necessary to the exhibition of a DESIGN, *q.v.*

SEDILIA, seats used by the celebrants during the pauses in the mass. They are generally three in number, for the priest, deacon, and sub-deacon, and are in England almost always a species of niches cut into the south walls of churches, separated by shafts or by species of mullions, and crowned with canopies, pinnacles, and other enrichments more or less elaborate. The piscina and aumbry sometimes are attached to them. Abroad, the sedilia are often movable seats: a single stone seat has rarely been found as at Lenham; but some have considered this to be a confessional chair, and others a frith-stole, or place to which criminals fled for sanctuary.

SEPULCHRE, EASTER, a recess in the wall of a church generally in the north side, often ornamented with a canopy, finials, &c., for the crucifix to stand in during certain rites from Good Friday to Easter Day.

Set-off, the horizontal line shown where a wall is reduced in thickness, and consequently the part of the thicker portion appears projecting before the thinner. In plinths this is generally simply chamfered. In other parts of work the set-off is generally concealed by a projecting string. Where, as in parapets, the upper part projects before the lower, the break is generally hid by a corbel table. The portions of buttress caps which recede one behind another are also called sets-off.

Severy (probably connected with the English word *sever*), any main compartment or division of a building. (See Bay.) The word has been supposed to be a corruption of Ciborium, as Gervase of Canterbury uses the word in this sense; but he probably alludes to the *vaulted* form of the upper part of the groining of each severy. (See Ciborium.)

Shaft (Fr. *colonnette*, Ital. *colonnetto*, Ger. *Schaft*), in classical architecture that part of a column between the necking and the apophyge at top of the base. In later times the term is applied to slender columns either standing alone or in connection with pillars, buttresses, jambs, vaulting, &c.

Shed Roof or **Lean-to**, a roof with only one set of rafters, falling from a higher to a lower wall, like an aisle roof.

Shingle (Med. Lat. *scandula, scindula*, Fr. *bardeau, essente*, Ital. *scandola*, Ger. *Schindel*), a sort of wooden tile, generally of oak, used in places where timber is plentiful, for covering roofs, spires, &c. In England they are generally plain, but on the Continent the ends are sometimes rounded, pointed, or cut into ornamental form.

Shrine (Med. Lat. *feretorium, scrinium*, Fr. *châsse, écrin*, Ital. *scrigno*), a sort of ark or chest to hold relics. Sometimes they are merely small boxes, generally with raised tops like roofs; sometimes actual models of churches; sometimes large constructions like that at St Albans, that of Edward the Confessor at Westminster, of St Geneviève at Paris, &c. Many are covered with jewels in the richest way; that of San Carlo Borromeo, at Milan, is of beaten silver.

Sill or **Sole** (Lat. *solum*, a threshold, whence the Fr. *seuil*), the horizontal base of a door or window-frame. A technical distinction is made between the inner or wooden base of the window-frame and the stone base on which it rests,—the latter being called the sill of the window, and the former that of its frame. This term is not restricted to the bases of apertures; the lower horizontal part of a framed partition is called its sill. The term is sometimes incorrectly written cill.

Sleeper (Fr. *dormant*), a piece of timber laid on low cross walls as a plate to receive ground joists.

Slype, a name for the covered passage usually found in monasteries between the end of the transept and the chapter-house.

Soffit (Ital. *soffitta*, a ceiling), the inverted horizontal face of anything, as, for example, of an entablature resting on and lying open between the columns or the underface of an arch where its thickness is seen.

Solar, **Soller** (Med. Lat. *solarium*, Fr. *galetas*, Ital. *solaio*), a room in some high situation, a loft or garret, also an elevated chamber in a church from which to watch the lamps burning before the altars.

Sole. See Sill.

Sommer (Fr. *sommier*), a girder or main-beam of a floor; if supported on two story posts and open below, it is called a *brace-summer*.

Sound Board (Fr. *abat-voix*), the covering of a pulpit to deflect the sound into a church. (See Testee.)

Span, the width or opening of an arch between the walls, &c., from which it springs, also the width of a roof between the plates.

Span Roof, a roof having two sides inclining to a centre or ridge, in contradistinction to a Shed Roof (which see).

Spandril or **Spandrel**, the space between any arch or curved brace and the level label, beams, &c., over the same. The spandrils over door-ways in Perpendicular works are generally richly decorated. At Magdalene College, Oxford, is one which is perforated, and has a most beautiful effect. The spandril of doors is sometimes ornamented in the Decorated period, but seldom forms part of the composition of the doorway itself, being generally over the label.

Spire (Fr. *aiguille, flèche*, Ital. *guglio*, Ger. *Spitze*), a sharply-pointed pyramid or large pinnacle, generally octagonal in England, and forming a finish to the tops of towers. In this country, in Norman times, the only attempt at anything like a spire consisted in the termination of some turrets, as those at Rochester, at St Peter's, Oxford, &c.; but these are rather Pinnacles (which see) than spires. Later Norman spires are supposed to have been merely low pyramidal roofs. In the Early English period they appear at first to have been low, as the remains of the one at Christ Church, Oxford, show; but afterwards they become much more lofty and sharply pointed. The probability is that the sight of the high domes and aspiring minarets of the Holy Land had suggested the erection of these lofty monuments to the Crusaders. At this period the spires generally covered the whole tower top, and had launchings where the square broke into the octagon. In the Decorated period the spires became still slenderer and sharper; the broach spire gradually gave place to those rising at once in octagon form from the flat of the towers surrounded with parapets, often richly perforated, and with pinnacles at the angles. The spires themselves often are decorated with ball-flowers and crockets, and sometimes have broad horizontal bands of tracery at intervals. In both these styles spire lights or *lucarnes* are common. Perpendicular spires partake also of most of these characteristics, except that they scarcely furnish an example of a broach spire. It is remarkable with how little material some of the loftiest spires have been erected, that at Salisbury being barely 9 inches thick for a great part of its height. On the Continent the spire seems to have been used earlier than with us. That at Brantôme is a mere low pyramid. At Saintes it is a low carved cone, with something of domical character. At Roullet it is a sharp circular cone, with four open pinnacles at the base. At Isomes it is octagonal, and as sharp as many of our Early English spires. In all these examples the windows below are semicircular. Timber spires are very common in England. Some are covered with lead in flat sheets, others with the same metal in narrow stripes laid diagonally. Very many are covered with shingles. Abroad there are some elegant examples of spires of open timber work covered with lead.

Spire-Lights. See Lucarne.

Springer, the stone from which an arch springs; in some cases this is a capital, or impost, in other cases the mouldings continue down the pier. The lowest stone of the gable is sometimes called a springer.

Spur, **Sperver**. The word *spur* is often applied to the carved wooden brackets or *hanses* which support the penthouse of a door, the level part being called a *sperver*.

Squinches, small arches or corbelled sets-off running diagonally, and, as it were, cutting off the corners of the interior of towers, to bring them from the square to the octagon, &c., to carry a spire. (See Pendentive.)

Squint, an oblique opening, often a mere narrow, square-headed slit, piercing the walls of the chancel arch, and evidently intended to afford a view of the high altar. Squints are often without any ornament, but are sometimes arched and occasionally enriched with open tracery. Sometimes they look from the rooms over porches, sometimes from side chapels, but in every instance are so situated that the altar may be seen. The most probable use of them was to let the acolyte appointed to ring the sanctus bell see the performance of mass, and enable him to sound the bell at the proper time.

Stage, an elevated floor, particularly the various stories of a bell-tower, &c. The term is also applied to the plain parts of buttresses between cap and cap where they set back, or where they are divided by horizontal strings and panelling. It is used, too, by William of Worcester to describe the compartments of windows between transom and transom, in contradistinction to the word *bay*, which signifies a division between mullion and mullion. (See Story.)

Stall, a fixed seat in the choir for the use of the clergy. In early Christian times the *thronus, cathedra*, or seat of the bishop, was in the centre of the apsis or bema behind the altar, and against the wall; those of the presbyters also were against the wall, branching off from side to side round the semicircle. In later times the stalls occupied both sides of the choir, return seats being placed at the ends for the prior, dean, precentor, chancellor, or other officers. The seats are very peculiar. (See Miserere.) In general, in cathedrals, each stall is surmounted by tabernacle work, and rich canopies, generally of oak, of which those at Winchester, Henry VII.'s Chapel, and Manchester, may be quoted as fine instances. (See Tabernacle, Canopy.) The word is sometimes used to express any chief seat, as in a dining hall.

Stanchion, a word derived from the French *étançon*, a wooden post, and applied to the upright iron bars which pass through the eyes of the saddle bars or horizontal irons to steady the lead lights. The French call the latter *traverses*, the stanchions *montans*, and the whole arrangement *armature*. Stanchions frequently finish with ornamental heads forged out of the iron.

Stay Bars, saddle bars passing through the mullions in one length across the whole window, and secured to the jambs on each side. (See Saddle Bar.)

Steeple (Fr. *clocher*, Ital. *campanile*, Ger. *Glockenthurm*), a general name for the whole arrangement of Tower, Belfry, Spire, &c. (See under those headings.)

Stele (Gr. στήλη, Lat. *cippus*, a small monument), the ornament on the ridge of a Greek temple, answering to the antefixæ on the summit of the flank entablatures.

Stereobate (Gr. στερεός, solid, and βάσις, a base), a basement, distinguished from the nearly equivalent term Stylobate, *q.v.*, by the absence of columns

Stilted, anything raised above its usual level.

Stoa (Gr. στοά, a portico), the Greek equivalent for the Latin Porticus, and the Italo-English Portico, *q.v.*

STORY (Lat. *tabulatum*, Fr. *étage*, Ital. *piano*, Ger. *Geschoss*). When a house has rooms one over the other, each set of chambers divided horizontally by the floors is called a story. They are thus named in the different languages :—

	English.	French	Italian.	German.
Lowest story.	Basement.	Souterrain—Cave.	Sotterraneo.	Kellergeschoss.
Ground do.	Ground floor.	Rez de chaussée.	Pianterreno.	Bodengeschoss.
Half story or intermediate.	Mezzanine.	Entresol.	Mezzanino.	...
First story.	First floor.	Premier étage, also Bel etage.	Primo piano, also piano, nobile.	Hauptgeschoss.
Second story.	Second floor.	As their	numbers.	...
Upper story.	Garret.	Mansard.	Solaio.	Dachgeschoss.

STOUP (Fr. *bénitier*), a vessel placed close to the entrance of a church to contain the holy water. They are generally small bowls fixed against a column, or on a stem. In the north of Italy they are larger, and often carried on the back of a lion, and sometimes they are elegant *tazze* of exquisite workmanship.

STRING or STRING-COURSE, a narrow, vertically-faced, and slightly projecting course in an elevation. If window-sills are made continuous, they form a string-course; but if this course is made thicker or deeper than ordinary window-sills, or covers a set-off in the wall, it becomes a blocking-course.

STRING-COURSES, horizontal mouldings running under windows, separating the walls from the plain part of the parapets, dividing towers into stories or stages, &c. Their section is much the same as the labels of the respective periods; in fact, these last, after passing round the windows, frequently run on horizontally and form strings. Like labels they are often decorated with foliages, ball-flowers, &c.

STRIP PILASTER, a very narrow pilaster.

STUDS, an old name for upright quarters or posts; thus door-studs are door-posts or jambs.

STYLE (Gr. στῦλος, a column). The term style in architecture has obtained a conventional meaning beyond its simpler one, which applies only to columns and columnar arrangements. It is now used to signify the differences in the mouldings, general outlines, ornaments, and other details which exist between the works of various nations, and also those differences which are found to exist between the works of any one nation at different times.

STYLOBATE (Gr. στῦλος, a column, and βάσις, a base), a basement to columns. (See STEREOBATE.) Stylobate is synonymous with pedestal, but is applied to a continued and unbroken substructure or basement to columns, while the latter term is confined to insulated supports.

SURBASE (Lat. *super*, whence the Fr. *sur*, above or upon, and BASE, *q.v.*), an upper base is the term applied to what, in the fittings of a room, is familiarly called the chair-rail. It is also used to distinguish the cornice of a pedestal or stereobate, and is separated from the base by the dado or die.

SYSTYLE (Gr. σύν, together with, and στῦλος, a column), having columns rather thickly set,—an intercolumniation to which two diameters are assigned. (See EUSTYLE.)

TABERNACLE, a species of niche or recess in which an image may be placed. In Norman work there are but few remains, and these generally over doorways. They are shallow and comparatively plain, and the figures are often only in low relief, and not detached statues. In Early English work they are deeper, and instead of simple arches there is often a canopy over the figure, which was placed on a small low pedestal. Later in the style the heads of the tabernacles became cusped, either as trefoils or cinquefoils, and they are often placed in pairs, side by side, or in ranges, as at Wells Cathedral. Decorated tabernacles are still deeper and more ornamented, the heads are sometimes richly cusped and surmounted with crocketed gables, as at York, or with projecting canopies, very much like the arcade at Lichfield. In this case the under side of the canopy is carved to imitate groin ribs, and the figures stand either on high pedestals, or on corbels. Perpendicular tabernacles possess much the same features, but the work is generally more elaborate; the figures generally stand on rich pedestals, but sometimes on corbels, and the canopies generally project, sometimes in a triangular form, and sometimes with a sort of domical top. (See CORBEL, CANOPY, NICHE, &c.) The word tabernacle is also often used for the receptacle for relics, which was often made in the form of a small house or church. (See SHRINE.)

TABERNACLE-WORK. The rich ornamental tracery forming the canopy, &c., to a tabernacle is called tabernacle-work; it is common in the stalls and screens of cathedrals, and in them is generally open or pierced through.

TABLE, TABLET, a name for various mouldings, as string-courses, cornices, &c.

TERMINAL. Figures of which the upper parts only, or perhaps the head and shoulders alone, are carved, the rest running into a parallelopiped, and sometimes into a diminishing pedestal, with feet indicated below, or even without them, are called terminal figures.

TESSELLATED PAVEMENTS, those formed of *tesseræ*, or, as some write it, *tessellæ*, or small cubes from half an inch to an inch square like dice, of pottery, stone, marble, enamel, &c. (See MOSAIC.)

TESTER, anything placed horizontally over the head, as the sound-board of a pulpit, the flat boards over an old-fashioned bed, &c.

TETRASTOÖN (Gr. τέτρα, four, and στόα, a portico). An atrium or rectangular court-yard, having a colonnade or projected orthostyle on every side, is called a tetrastoön.

TETRASTYLE (Gr. τέτρα, four, and στῦλος, a column), a portico of four columns in front.

THOLOBATE (Gr. θόλος, a dome or cupola, and βάσις, a base or substructure), that on which a dome or cupola rests. This is a term not in general use, but it is not the less of useful application. What is generally termed the attic above the peristyle and under the cupola of St Paul's would be correctly designated the tholobate. A tholobate of a different description, and one to which no other name can well be applied, is the circular substructure to the cupola of the University College, London.

THROUGH CARVING, a term supposed to signify such as is much undercut, as the tendrils, stalks, &c., in Decorated, and the vignettes in Perpendicular work. In the Durham roll it clearly means perforated work, as it is "to giue ayre."

TILES, ROOF (Lat. *tegula*, *imbrex*, Fr. *tuile*, Ital. *tegola*), flat pieces of clay burned in kilns, to cover roofs in place of slates or lead. In England, in mediæval times, the flat or planetile seems only to have been used, judging from what we find now left. From MS. and remains abroad, a kind of plane-tile, with ornamented ends, forming a sort of scale covering, seems to have been in vogue.

TORUS (Lat.), a protuberance or swelling, a moulding whose form is convex, and generally nearly approaches a semicircle. It is most frequently used in bases, and is generally the lowest moulding in a base.

TOWER (Gr. Πύργος, Lat. *turris*, Fr. *tour*, *clocher*, Ital. *torre*, Ger. *Thurm*), an elevated building originally designed for purposes of defence. Those buildings are of the remotest antiquity, and are, indeed, mentioned in the earliest Scriptures. In mediæval times they are generally attached to churches, to cemeteries, to castles, or are used as bell-towers in public places of large cities. In churches, the towers of the Saxon period are generally square, the only round example being supposed to be that of Tasburgh. They are not very lofty, and are of strong, rude workmanship. Two only, Brigstock and Brixworth, have staircases supposed to be original; both these are on the west front of the tower. The masonry partakes of the usual character attributed to Saxon work, as strip pilasters, long and short work, &c. The upper windows are generally circular-headed in two lights, separated by a shaft much resembling a turned baluster sometimes with heavy projecting caps. Norman towers are also generally square. Many are entirely without buttresses; others have broad, flat, shallow projections, which serve for this purpose. The lower windows are very narrow, with extremely wide splays inside, probably intended to be defended by archers. The upper windows, like those of the preceding style, are generally separated into two lights, but by a shaft or short column, and not by a baluster. Sometimes these towers have arcades round them, and are ornamented, as at St Albans, in some cases very richly, as at Norwich, Winchester, Tewkesbury, Southwell, Sandwich, &c. They frequently have stone staircases at one of the angles. In many of our churches the Norman tower is placed between the chancel and nave, and is of the full width of the latter. For the covering of these towers abroad, see SPIRE, PINNACLE, PARAPET. A few round towers of this period (and also of the next) are found on the coasts of Norfolk and Suffolk; as these mostly have no external doors, and are accessible only from the church, and as some have chimneys, they are supposed to have been built as places of refuge in case of invasion. Early English towers are generally taller, and of more elegant proportions. They almost always have large projecting buttresses, and frequently stone staircases. The lower windows, as in the former style, are frequently mere arrow-slits; the upper are in couplets or triplets, and sometimes the tower top has an arcade all round, as at Middleton Stoney. The spires are generally BROACH SPIRES (which see); but sometimes the tower tops finish with corbel courses and plain parapets, and (rarely) with pinnacles. Some of the towers and spires, particularly in the midland counties, are richly ornamented; a very good specimen is at Raunds. A few Early English towers break into the octagon from the square towards the top, and still fewer finish with two gables, as at Brookthorpe and Ickford. Both these methods of termination, however, are common on the Continent. At Vendôme, Chartres, and Senlis, the towers have octagonal upper stages surrounded with pinnacles, from which elegant spires arise. Decorated towers differ but little from these last, except that they are often lighter in effect; the buttresses, too, are set angularly; the parapets are also frequently embattled, or perforated in elegant designs, and these generally have pinnacles. The spires, also, now generally arise at once from the octagon, and are not broach spires; those that are of this latter character have the haunchings much smaller. There is a fine example of a Decorated tower and spire at Ellington, in Huntingdonshire. Most Perpendicular towers are very fine, particularly the great central towers, as at Canterbury and Gloucester. They are generally richly panelled throughout; the buttresses project boldly, and are sometimes set anglewise, and sometimes square, not close to each other, but showing a small portion of the angle of the tower where they otherwise would have intersected. The pinnacles are often richly canopied and the battlements panelled, and often perforated; sometimes a pinnacle, and sometimes a canopied niche, is placed in the middle of the parapet. At Boston, and in several other places, there are fine lanterns at the tops of the towers. Taunton, Evesham, Louth, Magdalene College, Oxford, and very many other places, have very fine Perpendicular towers. In the north of Italy, and in Rome, they are generally tall, square shafts in four to six etages, without buttresses, with couplets or triplets of semicircular windows in each stage, generally crenellated at top, and covered with a low pyramidal roof. The well-known hanging tower at Pisa is cylindrical, in five stories of arcaded colonnades. In Ireland there are in some of the churchyards very curious round towers.

TRACERY, the ornamental filling in of the heads of windows, panels, circular windows, &c., which has given such characteristic beauty to the architecture of the 14th century. Like almost everything connected with mediæval architecture, this elegant and sometimes fairy-like decoration seems to have sprung from the smallest beginnings. The circular-headed window of the Normans gradually gave way to the narrow-pointed lancets of the Early English period, and as less light was afforded by the latter system than by the former, it was necessary to have a greater number of windows; and it was found convenient to group them together in couplets, triplets, &c. When these couplets were assembled under one label, a sort of vacant space or spandril was formed over the lancets and under the label. To relieve this, the first attempts were simply to perforate this flat spandril, first by a simple lozenge-shaped or circular opening, and afterwards by a quatrefoil. By piercing the whole of the vacant spaces in the window head, carrying mouldings round the tracery, and adding cusps to it, the formation of tracery was complete, and its earliest result was the beautiful geometrical work such as is found at Westminster Abbey. When this style had reached perfection the usual decline followed; and the architects of the Decorated period designed tracery, beautiful in itself, but which wants the vigour of the geometrical, and appears more as if the stonework had been twisted than if it had been cut out of the solid. Nevertheless, however fanciful the design may be, the whole element is really geometrical—that is, it is formed of portions of circles, the centres of which fall on the intersections of certain geometrical figures. The great east window at Carlisle is composed of 86 distinct pieces of stone, and is struck from 263 centres; and the glorious west window at York is probably produced from a still greater number. Probably as a reaction against the weakness of the Decorated, the flowing tracery gradually admitted upright straight lines into its element. This change was perhaps made to afford, as it were, rectilineal frames to suit the glass painter, the foliages and medallions of the preceding styles having given way to single figures, standing on pedestals under rich canopies. Be this as it may, these have given a name to the style of the 15th and 16th centuries. The mullions then, as at King's College Chapel, at St John's, Oxford, and in several other examples, had more flow, and fewer perpendicular lines, till at last plain, upright, and transverse bars took their place, and held casement lights, which were at last superseded by our modern sash windows. On the Continent, the windows of the first period, or *ogivale primitive*, were very much like our own Early English. So in like manner those of the early part of the *ogivale secondaire* were very much like our own Geometrical Decorated. Later, however, in France and Germany, two styles prevailed, the *Rayonnant* and *Flamboyant*, the one having tracery assuming the character of stars or rays, and after this another coeval with our Perpendicular, resembling flames of fire.

TRACHELIUM (Gr. τράχηλος, the neck). In Doric and Ionic columns there is generally a short space intervening between the hypotrachelium and the mass of the capital, which may be called the trachelium or neck.

TRANSEPT (Med. Lat. *crux*, Fr. *transept*, Ital. *crociata*, Ger. *Kreuzgang*), that portion of a church which passes transversely between the nave and choir at right angles, and so forms a cross on plan.

TRANSOM (Fr. *traverse*, Ital. *traversa*, Ger. *Querbalken*), the horizontal construction which divides a window into heights or stages. Transoms are sometimes simple pieces of mullions placed transversely as cross-bars, and in later times are richly decorated with cuspings, &c.

TRAYLE. See VIGNETTE.

TREFOIL (Lat. *trifolium*), a cusping, the outline of which is derived from a three-leaved flower or leaf, as the *quatrefoil* and *cinquefoil* are from those with four and five.

TRIFORIUM, the arcaded story between the lower range of piers and arches and the clerestory. The name has been supposed to be derived from *tres* and *fores*—three doors or openings—that being a frequent number of arches in each bay. Professor Willis, however, believed that the word is to be traced to a monkish latinisation of "thoroughfare."

TRIGLYPH (Gr. τρεῖς, three, and γλυφή, an incision or carving). The vertically channelled tablets of the Doric frieze are called triglyphs, because of the three angular channels in them, two perfect and one divided,—the two chamfered angles or hemiglyphs being reckoned as one. The square sunk spaces between the triglyphs on a frieze are called metopes.

TUDOR FLOWER, or CRESTING, an ornament much used in the Tudor period on the tops of the cornices of screen work, &c., instead of battlements. It is a sort of stiff, flat, upright leaf standing on stems.

TURRET (Fr. *tourelle*), a small tower, especially at the angles of larger buildings, sometimes overhanging and built on corbels, and sometimes rising from the ground.

TYMPANUM (Gr. τύμπανον), the triangular recessed space enclosed by the cornice which bounds a pediment. The Greeks often placed sculptures representing subjects connected with the purposes of the edifice in the tympana of temples, as at the Parthenon and Ægina.

UNDER-CROFT, a vaulted chamber under ground.

VALURE, VAMURE. See ALURE.

VANE (Fr. *girouette*, Ital. *banderuola*, Ger. *Wetterfahne*), the weathercock on a steeple. They seem in early times to have been of various forms, as dragons, &c.; but in the Tudor period, the favourite design was a beast or bird sitting on a slender pedestal, and carrying an upright rod, on which a thin plate of metal is hung like a flag, ornamented in various ways.

VAULT (from Ital. *voltato*, turned over), an arched ceiling or roof. A vault is, indeed, a laterally conjoined series of arches. The arch of a bridge is, strictly speaking, a vault. Intersecting vaults are said to be groined. (See GROINED VAULTING.)

VAULTING SHAFT, a small column or series of clustered shafts, rising from above the capitals of the pillars of an arcade, and generally supported on a corbel, and thence rising and finishing with a capital, from which the various groin ribs spring.

VERGE, the edge of the tiling projecting over the gable of a roof; that on the horizontal portion being called *eaves*.

VERGE BOARD, often corrupted into Barge Board, the board under the verge of gables, sometimes moulded, and often very richly carved, perforated, and cusped, and frequently having pendents and sometimes finials at the apex.

VESICA PISCIS (Fr. *amande mystique*), panels, windows, and other ornaments of the form of a species of oval with pointed end, but in reality struck from two centres, and forming part of two circles cutting each other.

VESTRY. See SACRISTY.

VIGNETTE, a running ornament, representing, as its name imports, a little vine, with branches, leaves, and grapes. It is common in the Tudor period, and runs or *roves* in a large hollow or *casement*. It is also called *Trayle*.

VOLUTE (Lat. *volutum*, from *volvo*, to roll up or over), the convolved or spiral ornament which forms the characteristic of the Ionic capital. The common English term is SCROLL, *q.v.* Volute, scroll, helix, and cauliculus, are used indifferently for the angular horns of the Corinthian capital.

VOUSSOIR, a name in common use for the various wedge-shaped stones of an arch.

WAGGON-CEILING, a boarded roof of the Tudor time, either of semicircular or polygonal section. It is boarded with thin oak, and ornamented with mouldings forming panels, and with loops at the intersections. (See PANEL.)

WARD, a name for the inner courts of a fortified place. At Windsor Castle they are called the upper and lower wards. (See BAILEY, BASE COURT, ENCEINTE, &c.)

WEATHERING, a slight fall on the top of cornices, window sills, &c., to throw off the rain.

WICKET (Fr. *guichet*, Ital. *portello*), a small door opening in a larger. They are common in mediæval doors, and were intended to admit single persons, and guard against sudden surprises.

WIND BRACES, diagonal braces to tie the rafters of a roof together and prevent *racking*. In the better sort of mediæval roofs they are arched, and run from the principal rafters to catch the purlins.

ZOÖPHORUS (Gr. ζῷον, an animal, and φέρω, to bear). This term is used in the same sense as frieze, and is so called because that part of the entablature frequently bore sculptures representing various animals

ARCHIVES (Greek $\grave{\alpha}\rho\chi\epsilon\hat{\iota}o\nu$, Lat. *archivum*), a room or building in which are kept the records, charters, and other papers belonging to any state, community, or family. Very frequently the name is applied to the documents themselves. The archives of Britain are now superintended by the Public Record Office.

ARCHON ($\check{\alpha}\rho\chi\omega\nu$), the title of the highest magistrates in Athens. The last king of Athens, Codrus, having given up his life for the advantage of the state, it is said that the people, out of gratitude for his noble act, passed a resolution that in future none of their rulers should bear the ancient and venerated title of king ($\beta\alpha\sigma\iota\lambda\epsilon\acute{\upsilon}s$). The holder of supreme power in the state received from that time the name of archon or ruler. This is the popular account of the change, but it is not improbable that, on the death of Codrus, disputes arose with regard to the succession, and that the nobles took advantage of the opportunity to gain an addition to their own power. For the archon appears to have been in all respects equal to the king, and his office was hereditary, but he was made responsible for his acts to the Eupatridæ or nobles. Thirteen descendants of Codrus successively held the office. In 752 B.C., during the archonship of Alcmæon, the time of office was reduced to ten years, though the office itself remained hereditary. Seven decennial archons are enumerated, extending from 752 to 684. But during this time, about the year 714, a very important change had been introduced into the archonship. The office at that date ceased to be hereditary; the exclusive right of the Medontidæ was abolished, and the whole body of nobles became eligible for the magistracy. In 684 a further change was effected; the office was made annual, and the supreme power was distributed among nine officials, each of whom received the title of archon. This arrangement of the magistracy continued till the time of Solon, who introduced the classification of the citizens according to property and not to birth, and threw the office open to all who possessed an income of the first class, apparently calculated as five hundred measures of corn, wine, and oil (Plutarch, *Aristides*, 1). The most extensive and important change was introduced by Aristides, who after the battle of Platæa threw open the highest magistracy to all citizens, whether of the propertied class or not. The mode of election to the archonship, after the office was taken from the family of Codrus, was by the suffrage ($\chi\epsilon\iota\rho o\tau o\nu\acute{\iota}\alpha$) of the nobles; and this continued to be the case even after the reform effected by Solon, for it is expressly stated that though he altered the qualification he made no change in the manner of election. The great reform in this respect was probably due to Clisthenes, who in 508 introduced the election by lot, and who further, by his distribution of the people into tribes and appointment of generals, seriously impaired the power of the archons. To secure that the office and honours were not conferred on unworthy persons, the newly elected archons were subjected to a double scrutiny, before the senate and in the agora, in which they were required to show that they were true Athenian citizens, whose ancestors had been citizens for three generations, and to swear that they would obey the laws and revere the religion of their country.

Of the nine archons to whom in conjunction were entrusted the duties of the supreme magistracy, the first was called specially "The Archon" ($\acute{o}\ \check{\alpha}\rho\chi\omega\nu$); there was also attached to his name the epithet *eponymus* ($\grave{\epsilon}\pi\acute{\omega}\nu\upsilon\mu o s$), because the year in which he held office was named after him, just as at Rome it was named after the two consuls. At first this archon had the general administration of state affairs, but gradually the expansion of democratic power reduced his authority, and at the period of which we have accurate information his duties were not very extensive. He had the superintendence of the festivals of the greater Dionysia and of the Thargelia, the arrangement of the tragic choruses, and the conduct of certain sacrifices. As a special department of civil administration, he had under his care all orphans, particularly heiresses, all widows, and others who were left without protection, provided they were citizens of Athens; and had, in short, the charge of all matters in which questions of inheritance were involved. When his power was still further reduced, there remained to him the privilege of bringing disputed cases of succession into the proper courts, and of casting lots for the dicasts who were to try the cause. The second archon had the title of king ($\beta\alpha\sigma\iota\lambda\epsilon\acute{\upsilon}s$); to him had been handed over the name, as well as the sacred duties of priesthood which formerly belonged to the supreme ruler. He was the *rex sacrorum*, and to his province pertained all that concerned the religion and public worship of the state. In conjunction with his wife, who was called $\beta\alpha\sigma\acute{\iota}\lambda\iota\sigma\sigma\alpha$ (or queen), he offered up certain state sacrifices; and he had specially intrusted to him the superintendence of the mysteries, the festival of the Lenæa, the torch races, and the gymnic contests. He acted as public prosecutor in matters of religion; and, in cases of murder or offence against the gods, he brought the indictment into the Areopagus, and voted with its members. In later times he acted as president of the court in all cases concerning the rights and duties of priests. The third archon bore the title of polemarch ($\pi o\lambda\acute{\epsilon}\mu\alpha\rho\chi o s$), which indicates that originally he was the supreme commander of the Athenian forces. As late as the battle of Marathon we find the polemarch Callimachus marching along with the ten generals, and taking the command of the right wing. But after this we no longer hear of the polemarch as actively engaged in leading the army. Doubtless the introduction of the ten generals by Clisthenes tended to limit the military functions of this archon. His duties in later times seem to have been the superintendence and protection of the personal and family rights of the resident aliens and foreigners. To these he stood in the same relation as the archon eponymus stood to citizens. He had also the arrangement of the funeral games in honour of those who had fallen in battle, and the offering up of the annual sacrifice to Artemis in commemoration of the battle of Marathon. Each of the three superior archons was allowed to select two assessors or assistants ($\pi\acute{\alpha}\rho\epsilon\delta\rho o\iota$), who were sanctioned after examination by the senate. The remaining six archons were called thesmothetæ ($\theta\epsilon\sigma\mu o\theta\acute{\epsilon}\tau\alpha\iota$), a name which is sometimes applied to the whole body of archons. The six formed a college of justice, whose jurisdiction seems at first to have extended to all cases not directly under the cognisance of other magistrates. They received information against parties for various offences, brought the cases to trial in the proper court, appointed the juries, and gave public notice of the days of sitting. They revised every year the body of laws to see that no discrepancies were allowed to creep in, and they were required to enter all new laws. They also drew up and ratified the treaties with foreign states. Their assessors were called symbuli ($\sigma\acute{\upsilon}\mu\beta o\upsilon\lambda o\iota$). After the introduction of popular courts by Solon, the archons seem to have lost their special juridical powers; they then acted simply as presidents of the courts and sometimes as a grand jury. During their year of office the archons were exempt from all state burdens, and at its close they were required to give an account of the manner in which they had discharged their duties; if found blameless, they became members of the Areopagus.

The name archon is frequently applied by Greek authors to magistrates in general; it was also used as a title under the Greek empire, and the Jews sometimes applied it to members of their Sanhedrim. It was even given metaphorically by the Gnostice to their mystic æons.

ARCHYTAS, of Tarentum, son of Mnesagoras or Histiæus, was one of the most celebrated men of antiquity. He was distinguished as a mathematician, a philosopher, a statesman, and a general; nor was he less remarkable for the purity and integrity of his life and the mildness and benevolence of his disposition. The time at which he flourished can be settled approximately from the fact that he was contemporary with Plato, whom he knew personally, and whose life he saved by interceding with the tyrant Dionysius. He took a prominent part in the administration of the state, and was seven times made general of the army, although by a law it was forbidden that any citizen should hold the command more than once. It is said that he was never defeated in battle. He was also intrusted with the charge of many important civil affairs. There seems to have been a tradition (see Horace, *Odes*, i. 28) that Archytas was drowned while crossing the Adriatic, but of this there is no certain information. Archytas belonged to the Pythagorean school of philosophy, and is said by some to have been the teacher of Philolaos. This, however, must certainly be an error. According to others, he was the eighth leader of the Pythagorean school. Fragments of writings, said to be his, on various points of ethical and metaphysical philosophy, are given by Stobæus, Simplicius, and others. To portions of these Aristotle has been supposed to owe his doctrine of the Categories and some of his principal ethical theories. But it seems quite clear that scarcely any of these fragments are genuine, and that they belong to the 1st or 2d century A.D., a period during which Eclecticism, and a consequent desire to find traces of later doctrines in old writers, were the prevailing influences. Such fragments as do appear genuine are of no philosophical value, and are generally on special subjects. Archytas is particularly celebrated as a mathematician. To him are ascribed a solution of the problem of the duplication of the cube, and the application of analysis to the resolution of geometrical problems. He was also a skilled mechanician, and was one of the first to apply mathematics to mechanics and music. On the fragments of Archytas see Hartenstein, *De Archy. Taren. frag.*, Leipsic, 1833; Gruppe, *Ueber d. Frag. d. Archy.*, 1840; and Beckmann, *De Pythagor. Reliquiis*; also Zeller, *Phil. d. Griech.* 2d ed. iii. 2, 88, *sqq.*

ARCIS-SUR-AUBE, the chief town of the arrondissement of the same name, in the department of Aube, in France, is situated, in long. 4° 9′ E., lat. 48° 31′ N., about 17 miles (28 kilometres) N. of Troyes, on the left bank of the river, just at the point where it becomes navigable. It is mentioned in the *Itinerary* of Antoninus; but successive fires (1719, 1727, and 1814) have destroyed the ancient buildings, and it is now a town built in modern style, with wide and regular streets. An old castle, where Brunehaut and afterwards Diana of Poitiers resided, looks down on it from a height, the only other building of interest being the church, which dates from the 16th century. A battle was fought here on the 20th and 21st of March 1814 between Napoleon and the Austro-Russian army under Schwarzenberg, which led the former to retire upon Vitry, leaving the way open to Paris. There are important hosiery manufactures in the town, and it carries on a large trade in grain and coal, besides being an emporium for the wooden wares of the Vosges. Arcis-sur-Aube is on the highway between Troyes and Chalons-sur-Marne, and by means of the Aube it has intercourse with Paris. It is a subprefecture, and in 1872 had a population of 2845.

ARCOS DE LA FRONTERA, a Spanish town in the province of Cadiz, on the river Guadalete, which flows past Santa Maria into the bay of Cadiz. It is built upon a high and precipitous rock, and commands magnificent views. The special designation "of the frontier" is due to its position as a border town after its capture from the Moors by Alphonso the Wise. Its horses, reared in the plains below, are famous in the ancient ballads of Spain. It contains two parish churches, a number of convents, and 15,378 inhabitants.

ARCOT, two districts and a city of British India, within the presidency of Madras, and under the jurisdiction of the governor of that province. The district of NORTH ARCOT lies between 12° 22′ and 14° 11′ N. lat.; and between 78° 17′ and 80° 12′ E. long. It is bounded on the N. by the districts of Cuddapah and Nellor; on the E. by the district of Chengalpat; on the S. by the districts of South Arcot and Salem; and on the W. by the Mysor territory. The area of North Arcot, according to the *Annals of Indian Administration* for 1871–72, is 15,146 square miles; the population, as ascertained by a census taken in July 1871, being 2,007,667 souls. The aspect of the country, in the eastern and southern parts, is flat and uninteresting; but the western parts, where it runs along the foot of the Eastern Gháts, as well as all the country northwards from Trivellam to Tripalí and the Karkambadi Pass, are mountainous, with an agreeable diversity of scenery. The elevated platform in the west of the district is comparatively cool, being 2000 feet above the level of the sea, with a maximum range of the thermometer in the hottest weather of 88°. The hills are composed principally of granite and sienite, and have little vegetation. Patches of stunted jungle here and there diversify their rugged and barren aspect; but they abound in minerals, especially copper and iron ores. The narrow valleys between the hills are very fertile, having a rich soil and an abundant water-supply even in the dryest seasons. The principal river in the district is the Palár, which rises in Mysor, and flows through North Arcot from west to east past the towns of Vellor and Arcot, into the neighbouring district of Chengalpat, eventually falling into the sea at Sadras. Although a considerable stream in the rainy season, and often impassable, the bed is dry or nearly so during the rest of the year. Other smaller rivers of the district are the Painí, which passes near Chittur and falls into the Palár, the Sonámukhí, and the Chayaur. These streams are all dry during the hot season, but in the rains they flow freely and replenish the numerous tanks and irrigation channels. The principal roads in the district of North Arcot are the Trunk road from Madras to Bangalor, running from east to west; a road from north-east to south-west from Madras through North Arcot to Coimbator; and a road running north and south from Chittur to Arcot. The Madras Railway, and the Great Southern Indian Railway, also pass through the district. Grain of many species and cotton are largely grown throughout North Arcot, as well as sugar-cane and indigo. A part of the latter is sent to the Madras market. Cotton cloth is largely manufactured, and oil is prepared in considerable quantities for local consumption and for export. For fiscal purposes, the district is divided into the following fifteen *táluks*:—(1.) Chittur, (2.) Tripalí, (3.) Káverí Pak, (4.) Sholingarh, (5.) Trivellam, (6.) Sátgarh, (7.) Caddapanatam, (8.) Arcot, (9.) Vellor, (10.) Trivatur, (11.) Polur, (12.) Wandiwash, (13.) Satwaid, (14.) Penmari, and (15.) Venkatagiri Kota.

ARCOT, SOUTH, lies between 11° 0′ and 11° 39′ N. lat., and between 78° 42′ and 80° 4′ E. long. The district of South Arcot is bounded on the N. by the districts of North Arcot and Chengalpat; on the E. by the French territory of Pondecherri and the Bay of Bengal; on the S. by the British districts of Tanjor and Trichinopoly; and on the W. by the British district of Sálem. It contains an area, according to the *Annals of Indian Administration* for 1871–72, of 4779 square miles; and a population, as ascertained by a house census in July 1871, of 1,762,525. South Arcot is divided into thirteen fiscal divisions or táluks, as follows:—(1.) Tindevanum, (2.) Trivadi, (3.) Vilup-puran, (4.) Bhawangirí, (5.) Managudi, (6.) Chilambram, (7.) Trinsmáli, (8.) Vardháchalam, (9.) Elovansa, (10.) Trikalor, (11.) Kalakurchi, (12) Chaitpet, and (13.) Cuddalor. The aspect of the district resembles that of other parts of the Coromandel coast. It is low and sandy near the sea, and for the most part level till near the western border, where ranges of hills form the boundary between this and the neighbouring district of Sálem. These ranges are in some parts about 5000 feet high, with solitary hills scattered about the district. In the western tracts, dense patches of jungle furnish covert to tigers, leopards, bears, and monkeys. The principal river is the Coleroon or Kalerun, which forms the southern boundary of the district, separating it from Trichinopoly. This river is abundantly supplied with water during the greater part of the year, and two irrigating channels distribute its waters through the district. The other rivers are the Vellaur, Ponnár, and Gadalum, all of which are used for irrigation purposes. Numerous small irrigation channels lead off from them, by means of which a considerable area of fresh land has been brought under cultivation. Under the East India Company, a Commercial Resident was stationed at Cuddalor, and the Company's weavers were encouraged by many privileges. The manufacture and export of native cloth have now been almost entirely superseded by the introduction of European piece goods. The sea-ports of the district of South Arcot are Cuddalor or Fort St David, with a population, in 1855, returned at 36,686; and Porto Novo, with a population estimated, in 1855, at about 12,000 souls. The other places of importance in the district are Chilambram, Vardháchalam, Trivadi, Tiagár, Ginji or Chenji, Trinomáli, Chaitpet, Merkanam, and Verdur. The number of villages in South Arcot was returned, in 1850, at 3376. The total revenue of the district in that year amounted to £284,708, of which £234,055, or 82 per cent., represented the land revenue.

Arcot City, the principal town in the district of North Arcot, is situated on the south bank of the Palár river, in 12° 54′ N. lat., and 79° 24′ E. long. It is a station on the line of railway from Madras to Beypur, and is also a military cantonment. The population of the town, in 1862, was returned at 53,474 souls, inhabiting 10,042 houses. Arcot occupies a very prominent place in the history of the British conquests of India. In the middle of the last century, during the war between the rival claimants to the throne of the Carnatic, Muhammad Alí and Chandá Sáhib, the English supported the claims of the former and the French those of the latter. In order to divert the attention of Chandá Sáhib and his French auxiliaries from the siege of Trichinopoly, Clive suggested an attack upon Arcot, and offered to command the expedition. His offer was accepted; but the only force which could be spared to him, was 200 Europeans and 300 native troops to attack a fort garrisoned by 1100 men. The place, however, was abandoned without a struggle, and Clive took possession of the fortress. The expedition produced the desired effect; Chandá Sáhib was obliged to detach a large force of 10,000 men to recapture the city, and the pressure on the English garrison at Trichinopoly was removed. The siege of Arcot, in 1751, was conducted with great vigour by Rájá Sáhib, son of Chandá Sáhib, and is thus described by Macaulay:—

"Rájá Sáhib proceeded to invest the fort, which seemed quite incapable of sustaining a siege. The walls were ruinous, the ditches dry, the ramparts too narrow to admit the guns, and the battlements too low to protect the soldiers. The little garrison had been greatly reduced by casualties. It now consisted of 120 Europeans and 200 Sepoys. Only four officers were left, the stock of provisions was scanty, and the commander who had to conduct the defence under circumstances so discouraging was a young man of five-and-twenty, who had been bred a book-keeper. During fifty days the siege went on, and the young captain maintained the defence with a firmness, vigilance, and ability which would have done honour to the oldest marshal in Europe. The breach, however, increased day by day. Under such circumstances, any troops so scantily provided with officers might have been expected to show signs of insubordination; and the danger was peculiarly great in a force composed of men differing widely from each other in extraction, colour, language, manners, and religion. But the devotion of the little band to its chief surpassed anything that is related of the Tenth Legion of Cæsar, or the Old Guard of Napoleon. The Sepoys came to Clive, not to complain of their scanty fare, but to propose that all the grain should be given to the Europeans, who required more nourishment than the natives of Asia. The thin gruel, they said, which was strained away from the rice would suffice for themselves. History contains no more touching instance of military fidelity, or of the influence of a commanding mind. An attempt made by the governor of Madras to relieve the place had failed; but there was hope from another quarter. A body of 6000 Marhattás, half soldiers, half robbers, under the command of a chief named Murárí Ráo had been hired to assist Muhammad Alí; but thinking the French power irresistible, and the triumph of Chandá Sáhib certain, they had hitherto remained inactive on the frontiers of the Carnatic. The fame of the defence of Arcot roused them from their torpor; Murárí Ráo declared that he had never before believed that Englishmen could fight, but that he would willingly help them since he saw that they had spirit to help themselves. Rájá Sáhib learned that the Marhattás were in motion, and it was necessary for him to be expeditious. He first tried negotiations,—he offered large bribes to Clive, which were rejected with scorn; he vowed that if his proposals were not accepted, he would instantly storm the fort, and put every man in it to the sword. Clive told him, in reply, with characteristic haughtiness, that his father was a usurper, that his army was a rabble, and that he would do well to think twice before he sent such poltroons into a breach defended by English soldiers. Rájá Sáhib determined to storm the fort. The day was well suited to a bold military enterprise. It was the great Mahometan festival, the Muharram, which is sacred to the memory of Husain, the son of Alí. Clive had received secret intelligence of the design, had made his arrangements, and, exhausted by fatigue, had thrown himself on his bed. He was awakened by the alarm, and was instantly at his post. The enemy advanced, driving before them elephants whose foreheads were armed with iron plates. It was expected that the gates would yield to the shock of these living battering-rams. But the huge beasts no sooner felt the English musket balls than they turned round and rushed furiously away, trampling on the multitude which had urged them forward. A raft was launched on the water which filled one part of the ditch. Clive perceiving that his gunners at that post did not understand their business, took the management of a piece of artillery himself, and cleared the raft in a few minutes. Where the moat was dry, the assailants mounted with great boldness; but they were received with a fire so heavy and so well directed, that it soon quelled the courage even of fanaticism and of intoxication. The rear ranks of the English kept the front ranks supplied with a constant succession of loaded muskets, and every shot told on the living mass below. The struggle lasted about an hour; 400 of the assailants fell; the garrison lost only five or six men. The besieged passed an anxious night, looking for a renewal of the attack. But when day broke, the enemy were no more to be seen. They had retired, leaving to the English several guns and a large quantity of ammunition."

Arcot was afterwards captured by the French; but in 1760 was retaken by Colonel Coote after the battle of Wandiwash. It was also taken by Haidar Alí when that invader ravaged the Carnatic in 1780, and held by him for some time. The town of Arcot, together with the whole of the territory of the Carnatic, passed into the hands of the British in 1801, upon the formal resignation of the government by the Nawáb, Azím-ud-daulá, who received a liberal pension.

ARCTIC OCEAN. The Arctic Circle (66° 30′) being taken as a boundary, the whole of the ocean lying to the north is called the Arctic Ocean. From a physical point of view this limit is hardly satisfactory, since between Greenland and Europe the Atlantic, with its Gulf Stream, makes an inroad on the Arctic territory, and the southern extremity of Greenland brings down the Arctic region beyond the Arctic limit; but the other parallel of latitude (70°) which has been chosen as a southern limit is perhaps still more objectionable. The Arctic Ocean washes the north of Europe, Asia, and America. It communicates with the Atlantic by a broad opening on the east of Greenland, and a narrow but important channel on the west, which has been traced as far north as 84°, and is known in the various parts of its extent by special names—Davis' Strait, Baffin's Bay, Utlak Soak, Smith Sound, Kennedy Channel, Robeson Channel, Lincoln Sea,—but might conveniently be distinguished by some such general designation as the West Greenland Channel. With the Pacific there is communication between Asia and America through Behring's Strait. The coast line of all the three continents is for the most part exceedingly irregular, though this is less the case with Asia than with the other two. Europe sends down the Onega, Dwina, Pinega, Mezen, and Petchora; Asia the Obi, Yenisee, Lena, Indigarka, and Robima; and America the Mackenzie River. The most important of the numerous islands are Spitzbergen and Nova Zembla, with the multitudinous adjacent islets, to the north of Europe; the Liakhov Islands, or New Siberia, off the coast of Asia; and the vast irregular Archipelago into which the north-eastern portion of America is split, which extends to the quasi-continent of Greenland. While for human habitation the regions of the Arctic Ocean are the most desolate that can well be conceived, there is extraordinary abundance of the lower forms of animal life; and while for centuries men have only visited them to gather their living harvests, or for purposes of exploration, traces are in many places to be found of human inhabitants in a distant age. At a still remoter period the islands of the Arctic Archipelago have been covered with forests, and Barrow's Straits have been the habitat of coral and sponge (Markham, in the *Journ. Roy. Geogr. Soc.* 1865, p. 88). A very large portion of the area included by the Arctic Ocean is still unexplored; but almost every year diminishes the extent of the unknown. The nearest approach to the Pole has been made up the West Greenland Channel; the passage along the eastern coast away to the north of Spitzbergen being the next in order of success. For information regarding the various Arctic expeditions, see the article POLAR REGIONS.

ARDEA, a Latian city, probably of Pelasgian origin, famous chiefly for its accidental connection with the semi-mythical rape of Lucretia and the expulsion of the Tarquins from Rome. It lies 24 miles almost due S. from Rome, and 4 miles from the coast, on a small stream. It seems at one time to have been a place of great wealth and power; but the little hamlet which still preserves its name hardly numbers 200 inhabitants. A few fragments of tufa-built fortifications are the only remains of its ancient architecture.

ARDEBIL, or ARDABIL, one of the chief towns of Azerbijan in Persia, situated in 38° 15′ N. lat., and 48° 19′ E. long., on the Karasu or Balulk, a tributary of the Aras, in a fertile plain about 40 miles from the Caspian, seems to have been built out of the ruins of a former city. It is surrounded with a mud wall and towers, has a square castle with bastions at the corners fortified after European fashion, and contains the tomb of Shah Ismael Sufi, the founder of the Sufi dynasty of Persia. It is an emporium in the trade of Tiflis, Derbend, and Baku with Ispahan and Teheran. By a great council of the Persian empire, which met in 1736 in the neighbouring plain of Chowal-Mogam, Nadir Shah was chosen king, and his coronation took place next year at Ardebil. In the vicinity there are a number of warm mineral springs, and to the west stands the great mountain Sevilan, of volcanic origin, forming the eastern extremity of the water-shed between the Aras and the Tigris. From its remarkable salubrity Ardebil has acquired the Persian title of *Abadan i Firuz*, the abode of happiness.

ARDECHE, a department in the south of France, bounded on the N.W. by the department of Loire, on the E. by Isère and Drôme, on the S. by Gard, and on the W. by Lozère and Haute Loire. It extends 72 miles from N. to S., and 45 from E. to W., at the widest points; and its area is 2134 square miles. The surface of Ardèche is almost entirely covered by the Cevennes Mountains; the main line forming the western boundary of the department, and sending out the Boutières, Coiron, Tanargue, and other branches, for the most part in an easterly direction. Several of the summits, of which the highest, Mount Mezenc, is 5972 feet above the sea, are evidently extinct volcanoes. The Rhone bounds Ardèche on the east, and receives most of its rivers, including the Cance, the Ay, the Doux, the Erieux, and the Ardèche. A few rivers, however, belong to the Atlantic side of the water-shed, the chief being the Loire, which rises on the western borders of the department, and the Allier, which for a short distance separates it from Lozère. The climate in the valley of the Rhone is warm, and sometimes very hot; but westward, as the elevation increases, the cold becomes more intense and the winters longer. Some districts, especially in summer, are liable to sudden alterations in the temperature. Grain and pulse are produced, but not in quantities sufficient for the population, a large part of the fare of the peasants consisting of potatoes and chestnuts. The latter, besides, form one of the main articles of export, another being oil extracted from nuts. Wine is produced in considerable quantities along the valley of the Rhone. The rearing of the silk-worm, however, is of all the industries the most important and remunerative. Goats and sheep are kept in large numbers, Ardèche being one of the chief sources of the supply of skins for glove-making. The number of horses is small, asses and mules being the beasts of burden mainly employed. Iron, coal, lignite, marble, limestone, and porcelain clay are among the mineral products. Hot springs are numerous, and some of them, as St Laurent, Celles, and Neyrac, are largely resorted to. Natural curiosities are the *Pont d'Arc* over the Ardèche, and the *Chaussée des Géants*, near Vals. The country people adhere to their provincial habits and dialect, go barefoot, and wear tall hats and long blouses. Among the celebrated men of the department may be named Cardinal Tournon and the brothers Montgolfier. The chief town is Privas; the arrondissements are Privas, Largentière (which derives its name from its ancient silver mines), and Tournon. Population, 380,277

ARDELAN, a province of Persia, forming the eastern division of Kurdistan, and lying south of Azerbijan. Its capital Senna, in long. 40° E., and lat. 35° 12′ N., is built in a deep valley, which is well tilled and rich in orchards. The north part presents a succession of great table-lands, inhabited in the summer by wandering shepherds, who migrate in winter to the vicinity of Baghdad. The soil in the valleys is good, and abundance of wheat, barley, and the oil-plant (*Sesamum orientale*) is grown, besides a little tobacco. The oak forests of the mountains to the west yield fine timber, which is floated down the Tab into the Tigris, and gall-nuts, which are sent to India. The inhabitants, mostly Kurds, are greatly given to war and robbery, and many of the tribes are subjects of Persia only nominally.

ARDENNES, a department on the N.E. frontier of France, which derives its name from the famous forest, is bounded on the N. and N.E. by Belgium, on the E. by the department of the Meuse, on the S. by that of Marne, and on the W. by that of the Aisne. In shape it is an irregular pentagon, with a cape-like prolongation into Belgium on the north. It has a superficial extent of 523,000 hectares, or 1,291,810 acres, of which 300,000 hectares, or 741,000 acres, are arable land, while 154,000 hectares, or 383,800 acres, are occupied with forest, wood, and heath. The wooded plateaus which begin in the department of the Meuse are continued in a north-west direction, and divide the basin of the Meuse from the basin of the Aisne, till they form a junction with the Ardennes proper. At one time this was a very inaccessible region, and formed a strong defence, as Dumouriez showed in 1792, against invasion from the east. The Meuse (Maas), flowing in a northern direction, enters obliquely from the east, and cuts off a narrow and irregular strip along the Belgian side of the department, which it leaves at the extreme north, to flow through Belgium and join the western branch of the Rhine. The Aisne enters near the south-east corner and leaves at the south-west; its course through the department skirting the base of the Argonne range, and forming an irregular arc with its convexity to the north. The chief wealth of Ardennes consists in mineral productions, wood, cattle, and sheep The number of cattle in 1872 was 82,975, of sheep 393,044, of horses 49,748, and of pigs 51,809. The sheep are small, but are valued for the quality of their mutton. Agriculture has recently made considerable advances in the department. There are upwards of 150 iron-mines, as at Grandpré, Champigneulle, Raucourt, Brevilly, Monthermé, and Flize; a great number of excellent slate-quarries, as at Deville, Monthermé, Rimagne, and Fumay; while copper also is obtained in considerable quantities, and there is an abundant supply of building-stone, limestone, and marl. Peat is very common in the north, and coal is worked near Sedan. The people are well educated, active, and industrious, and can boast of having furnished from their ranks such men as Gerson, Robert de Sorbon, Mabillon, Corvisart, Marshal Macdonald, de Wailly, Léon Renier, H. Taine, and the publisher Hachette. It is said that they are marked by a special aptitude for the exact sciences. The department has about 240 miles of imperial road and 131 of departmental. Its two great rivers are united by the Canal des Ardennes. A branch of the Paris and Strasburg railway runs through it in a north-east direction, joining Rheims (in Marne) with Réthel and Mézières, and holding north along the valley of the Meuse to Namur (in Belgium). At Mézières this branch meets almost at right angles with a line running north-west, and connecting Thionville (in the district acquired by Germany) with Montmédy, Sedan, Maubert, &c. The department is divided into five arrondissements: Mézières, towards the centre; Rocroy, in the N.; Rethel, in the W. and S.; Vouziers in the S.; and Sedan in the E. Mézières is the capital, and a prefecture. Ecclesiastically the department, which has 46 cures, is part of the diocese of Rheims. It contains communal colleges and normal schools, and has 720 free public schools. The population in 1872 was 320,217, the falling off from 331,296 in 1851 being due to the war of 1870–71. See Elizé de Montagnac, *Les Ardennes Illustrées* (*France et Belgique*) 4 vols. fol. 1873.

ARDFERT, a small village in Kerry, in the S.W. of Ireland, about 4 miles N.N.W. of Tralee, and nearly as much from the coast. It had at one time a university, and was the seat of a very ancient bishopric; but both it and Aghadoe, with which it was combined, are united to the see of Limerick The cathedral, a very old building, was the church of St Brendan's monastery. A pillar tower, which stood near it, and was one of the finest and loftiest in the kingdom, fell in 1780. Population, 192.

ARDGLASS (*the green height*), a town of Ireland in Down county, Ulster, at the head of a small bay about 8 or 9 miles S. of the entrance of Strangford Lough, and 7 miles S.S.E. of Downpatrick, was a place of great importance soon after the Norman invasion. It had a considerable trade, was a royal burgh, and sent a representative to the Irish parliament. It is still remarkable for the ruins of five Anglo-Norman castles. Its permanent inhabitants, who are chiefly engaged in the fisheries, numbered only 613 in 1871; but its population during the bathing season is considerably increased by visitors. Ships of 500 tons may enter the harbour at all tides, and its inner cove admits vessels of 100 tons. There is a lighthouse at the end of the pier, in lat. 54° 15′ N., long. 5° 36′ W.

ARDOCH, a parish in Perthshire, famous for its Roman military antiquities, which are situated in the grounds of Ardoch House, about 2½ miles N. of Greenloaning, on the Caledonian Railway. They consist of—(1), a strong fort or station, surrounded by a series of ramparts and ditches, (2), vestiges of an intrenched outwork of considerable extent at the north side of this station; and (3), traces of two camps, still further to the north, capable, according to General Roy, of containing 28,800 and 14,000 men respectively, the smaller camp being partly included within the limits of the larger. See Gordon's *Itiner. Septent.*, p. 41; Pennant's *Tour*, iii. 102; Roy's *Military Antiquities*, pp. 62, 226; Stuart's *Caledonia Romana*, pp. 187–194.

ARDRES, a French town, in the department of Pas de Calais, and arrondissement of St Omer, on a canal joining Calais and St Omer, to which it gives its name. The "Field of the Cloth of Gold," where Henry VIII. of England and Francis I. of France tried to outdazzle each other in 1520, was in the immediate neighbourhood. The town contains several distilleries and breweries. Population, about 2200.

ARDROSSAN, a sea-port in Ayrshire, Scotland, 31 miles by rail from Glasgow, in N. lat. 55° 38′, and W. long. 4° 49′ It dates from an early period, as there seems to have been a castle and a small fishing village in existence for several centuries. The name of Arthur of Ardrossan is found in connection with a charter dated 1226; and Sir Fergus of Ardrossan accompanied Edward Bruce in his Irish expedition in 1316, and in 1320 signed the appeal to the Pope, by the barons of Scotland, against the aggressions of Edward I. of England. The castle, famous for its capture by Wallace, was finally destroyed by Cromwell, who is said to have used part of its masonry for the construction of the fort at Ayr. The family of the barons of Ardrossan is now merged, by marriage, in that of the earl of Eglinton and Winton. The rise of Ardrossan into commercial importance is due to the exertions of Hugh the twelfth earl of Eglinton, who commenced the construction of the present town and harbour in 1806. The harbour was intended to be in connection with a canal from Glasgow to Ardrossan, but this was only completed as far as Johnstone. Owing to the stoppage of the canal works, and the death of Lord Eglinton, the construction of the harbour was suspended till 1845, when it was partially completed and placed in connection with the Glasgow and South-Western Railway by a branch railway which joins the main line at Kilwinning. The cost of the harbour up to 1874 has been upwards of £200,000. The works now consist of a wet dock of 4 acres in area, with 19 feet at high water over the lock sill, and of two tidal harbours—one 18 acres, and the other 6 acres in area. There is a lighthouse on the north-west point of the outer breakwater, with a white flashing light. The works are well supplied with steam cranes, and all modern appliances for discharging and loading vessels. The exports consist principally of coal and iron from collieries and ironworks in the neighbourhood, and the imports of timber, ores, and general goods. There are lines of steamers plying to Glasgow, Arran, Belfast, Newry, and to various ports in Spain. In 1874 the number of vessels entering and leaving the port was 2044, with a registered tonnage of 296,690; the number of vessels belonging to the port was 114, with a registered tonnage of 15,611, and there were exported 276,081 tons of coal, and 80,516 tons of iron. Iron founding and shipbuilding are carried on to a considerable extent; and for the repair of vessels there are a graving-dock, which can take in vessels of 1500 tons, and a floating dock and patent slip, which can each accommodate vessels of 500 tons. In 1846 an Act of Parliament was obtained, erecting the town into a burgh, with a corporation consisting of a provost, two bailies, and five town councillors. The public buildings consist of a townhall, the property of the corporation, and of five churches, belonging to the Established Church, the Episcopal, the Free, the United Presbyterian, and the Evangelical Union denominations respectively. There are three branch banks in the town. The population in 1851 was 2071; it was 3929 in 1871; and in 1874 it is estimated to be 4228.

AREMBERG, a small market-town of Prussia, in the government of Coblentz and circle of Adenau. It is situated not far from the river Ahr, and has a castle which was formerly the residence of the dukes of Aremberg. About the year 1298 the earldom of Aremberg, which had previously belonged to a branch of the house of Hostaden, came by his marriage with Matilda to John of Engelbert, earl of Mark (Westphalia), and continued in his family till 1547, when John of Barbançon, of the celebrated house of Ligne, by marrying the only sister of the childless Robert III., obtained possession of the lands, which were raised by Maximilian II. to a principality, and ranked among the German states. John, who is remembered as the leader of troops from the Netherlands to serve against the Huguenots, having fallen (1568) in the battle of Heiligerlee, was succeeded by his son Philip Charles, admiral of Flanders, who greatly increased his possessions by marrying Ann of Croy, heiress of Croy, Arschot, Chimay, &c. He died in 1616, and was followed by his eldest son, stadtholder of Namur, who, having informed the Spanish government of a conspiracy, was rewarded by arrest (1634) and imprisonment at Berdessillas, where he died in 1640. Under his son, Philip Francis, Aremberg was raised to a dukedom (1644). Alexander Joseph and Philip Charles Francis both fell in battle against the Turks, the former in 1663, and the latter in 1691. Charles's widow, Maria Henrietta, left her country and possessions rather than recognise the duke of Anjou as king of Spain, and lived in dignified poverty till the battle of Ramilies gave back the Netherlands to their rightful possessor. She died in 1744. Her only son Leopold is known in history as a military leader (at Malplaquet, Belgrade, Ettinghen, &c.), and as the patron of Rousseau and Voltaire. His son and successor, Charles Leopold, was distinguished in the Seven Years' War as an Austrian field-marshal, and increased his possessions by marriage with Margaret of Mark. By the peace of Luneville (Feb. 1801), the next duke, Engelbert, lost the greater part of his ancestral domain, but received in compensation Meppen and Recklinghausen. On the establishment of the confederation of the Rhine, his son Prosper-Louis (to whom, becoming blind, he had ceded his domains in 1803) became a member (1807), and showed great devotion to the interests of France; but in 1810 he lost his sovereignty, Napoleon incorporating his dukedom with France and the grand duchy of Berg, and indemnifying him by a rent of 240,702 francs. In 1815 he received back his possessions, which were mediatised by the Congress of Vienna, part falling to Prussia and part to Hanover. On account of the one portion he became a peer of the Westphalian estates, and by the other, a member of the House of Lords in Hanover. George IV. of England, on 9th May 1826, elevated the duke's Hanoverian possessions to a dukedom under the title of Aremberg Meppen. His territory extended over 780 geographical square miles, with 94,000 inhabitants; of which, 544 square miles, with 50,000 inhabitants, were in Hanover; besides which he had large estates in France, and extensive tracts of forest in the Pyrenees. His brother Augustus-Raymond (b. 1753, d. 1833) became famous, under the title of Count of Mark, for his connection with the French Revolution and his friendship with Mirabeau. Duke Prosper-Louis died in 1861, and was succeeded by his son Engelbert.

ARENDAL, a sea-port town of Norway on the Skagerrack, 35 miles north-east of Christiansand. It is built at the mouth of the river Nidelf, on a number of small islands and rocks, the houses in many places being erected on piles. From its situation, and the number of canals by which it is traversed, it has acquired the name of Little Venice. There is a considerable shipping trade, particularly in iron and timber; and ship-building, distillation, and iron-mining are carried on. The neighbourhood is remarkable for the number of beautiful and rare minerals found there; one of these, a variety of epidote, was formerly called Arendalite. Louis Philippe lived here a long time during his exile. Population in 1855, 4456; in 1865, 5800.

AREOPAGUS (Ἄρειος πάγος), a small barren hill to the west and within bowshot of the Acropolis of Athens, for an attack upon which it would form a natural base. It was so used (480 B.C.) by the Persians (Herodotus, viii. 52). For the same purpose it had been occupied also in the legendary age by the Amazons, when in the time of Theseus they menaced Athens, and from the circumstance of their having then sacrificed to Ares, the hill, according to Æschylus (*Eumenides*, 685, *ff.*), derived its name. Assuming the occupation by the Amazons to have been typical of what frequently happened during the hostilities of early times, it is easy to understand how the hill came to be associated with the war god (Köhler, in the *Hermes*, 1872, p. 105). To the popular mind the Areopagus was always the "hill of Mars." But the popular mind required a more definite account of the origin of the name, and to supply this, there took shape the legend of Ares having been here called before a court of the twelve gods to answer for the murder of Halirrhotius (Pausanias, i. 285). This explains at once the origin of the name of the hill and of the court which held its sittings there. Æschylus, however, gives in the *Eumenides* a different origin to the court, declaring it to have been first appointed by Athene to try Orestes for the murder of his mother Clytæmnestra. In later times both legends were dismissed, and the explanation of the name referred to the nature of the cases—cases of murder—tried before the court (Suidas, *s. v.*, Ἄρειος πάγος· ἐπεὶ τὰ φονικὰ δικάζει· ὁ δὲ Ἄρης ἐπὶ τῶν φόνων). The four legendary cases of murder tried before this court were those in which Ares, Cephalus, Dædalus, and Orestes appeared as the accused. But the selection of this hill as the site of a criminal court, in the first instance, is to be sought for in the sacred relation in which it stood to the worship of the Erinnyes, or Eumenides, and not in its connection with Mars, for whom it had no sanctity, and between whose worship and that of the Erinnyes K. O. Müller (*Eumenides*, p. 178) has not succeeded in proving any community. On the top of the hill towards the east is an artificial plateau accessible from the south by steps cut in the rock. In several places are still to be traced the rock-hewn seats on which the court sat in the open air so that the judges and the accusers might not be under the same roof with a polluted criminal. The sittings were held by day, not by night, unless the authority of Lucian be accepted (*Hermot.*, 46; *De Domo*, 78). Raised upon two unhewn stones (ἀργοὶ λίθοι) the accuser and the accused made their pleadings, the stone used by the former being called λίθος ἀναιδείας, "stone of implacability," not of "impudentia" as translated by Cicero (*De Leg.*, ii. 11), or "impudence," as given by Dyer (*Athens*, p. 451); the other was called λίθος ὕβρεως, or "stone of crime."

Within the boundary of the court stood also an altar to Athene Areia, believed to have been dedicated by Orestes, and blocks of marble (ἄξονες), on which were inscribed the laws defining the powers of the judges. On another part of the hill stood one of the most revered of Athenian sanctuaries, that of the Erinnyes, containing statues of these three goddesses, but not in the hideous aspect in which they were usually conceived, and also statues of those other deities connected with the lower world, Pluto, Hermes, and Ge. Within the boundary of this temple was the tomb of Œdipus, and very close to the boundary, if not within it, was the heroön or sanctuary of Hesychus, the founder of the priestly line in whose hands were the rites of the Erinnyes. Near the temple was the Κυλώνειον, a memorial of the pollution of the spot caused by the treacherous slaughter of those who, having failed in the conspiracy of Cylon, had taken refuge there as suppliants (Herod., v. 71; Thucyd., i. 126). Towards the north-east foot of the hill was a temple of Ares containing statues of that god, of Enyo, Aphrodite, and Athene, while outside were statues of Hercules, Apollo, Pindar, and a poet named Caladas. On the north-east side there is a chasm in the rocks with a spring of dark water, which may have been associated with the worship of the Erinnyes.

The court and council of the Areopagus (ἡ βουλὴ ἡ ἐξ 'Αρείου πάγου or ἡ ἄνω βουλή), with a legendary history which distinctly pointed to it as an institution of primitive origin and intrusted with functions of the first importance, was yet in regard to the period of its history before Solon (594 B.C.) so little known that most people in later times had come to believe it to have been created by him (Plutarch, *Solon*, 19). As proof that the court had not existed before the time of Solon, it was urged that in the legislation of Draco (620 B.C.) there is no mention of the Areopagus, he having referred all such cases as in later times came within the powers of that court to a class of judges called the Ephetæ. But there is no reason why "Ephetæ" may not have been previous to Draco the title applied to the judges of the court of Areopagus, instead of "Areopagites," just as it was the title borne even after Solon by the judges of the other four Athenian courts which tried cases of bloodshed, unless we accept the statement of Pollux (viii. 18) that the appointment of the Ephetæ to all these courts, including the Areopagus, was the work of Draco. For then, these courts having admittedly been in existence before his time, there is no help but to assume that the judges had previously borne other titles, and that in the case of the Areopagus the title used could only have been Areopagites. But it is quite within fair criticism to throw aside this statement of Pollux, as has been done by the most recent writer on this subject (Philippi, *Rheinisches Museum*, 1874, p. 12), and to assume, with K. O. Muller, that the Ephetæ had acted from time immemorial as judges in all the five courts. There would remain for the fame of Draco the organisation of the courts, and possibly the limitation of the number of Ephetæ to 51. We must then conceive Solon as having found the Ephetæ acting as judges in the Areopagus and in the other four courts. He set himself to alter the constitution of the Areopagus by adding to the Ephetæ already in office there the nine Athenian archons on their retiring from public duties, and provided that they had rendered a satisfactory account of their administration. It is probable that from this new source alone a sufficient number of judges was supplied, and that, therefore, the original Ephetæ were allowed to die out, though in that case the number of Areopagites could scarcely have been a fixed one (given at 51 by the scholiast to the *Eumenides*, v. 743), considering the liability of an archon to be rejected. The new judges retained their office for life subject to dismissal only by their own body. For the most part they were advanced in years, and necessarily always men of integrity and experience, qualifications which were demanded in the highest degree from a court which, instead of administering strictly defined laws, had to base its verdicts on a careful investigation of the life and circumstances of parties arraigned before it. Its decisions were quoted as models of justice. Its competency was limited to cases of wilful murder (φόνος ἑκούσιος or ἐκ προνοίας), bodily injury with intent to kill (τραῦμα ἐκ προνοίας), incendiarism (πυρκαϊά), and poisoning (φάρμακα, ἐὰν τις ἀποκτείνῃ δούς). Other degrees of homicide were referred, according to their nature, to the other four Athenian courts, viz., accidental homicide (φόνος ἀκούσιος) to the Palladium, justifiable homicide (φόνος δίκαιος) to the Delphinium; at the Prytaneum was heard the formal indictment of inanimate objects, such as wood or stone, which by falling had caused the loss of life; while before the court of Phreathys at the Piræus appeared those who having been banished for accidental homicide had during their banishment committed wilful murder. There were, however, cases of a complicated nature in regard to which the records are far from explicit as to the courts to which they were referred. Of this kind was a case in which the actual perpetrator (χειρὶ ἐργασάμενος) was found to have been only a tool in the hands of a third person. It was with the latter that the prosecution had principally to deal, and against him was issued a charge of βούλευσις, or premeditation of murder. Obviously, such a person was equally guilty whether his victim died or not (Harpocration, *s.v.* βουλεύσεως), and therefore equally within the jurisdiction of one and the same court. Still it has been usual to follow Schömann (*Griech. Alterthümer*, i. p. 449) in drawing this distinction, that when death ensued the case went before the Areopagus, and before the Palladium when the victim survived. But this distinction has been made for the sake of admitting both authorities to be correct, when, on the one hand, Isæus and Aristotle (as quoted by Harpocration) refer βούλευσις to the Palladium, while Dinarchus (see Harpocration) on the other hand refers it to the Areopagus. It would be better to dismiss the authority of Dinarchus altogether, the more so since in a speech of Antiphon, admittedly in a case of βούλευσις (Choreutæ), a form of address is employed, ὦ ἄνδρες (once, ὦ ἄνδρες δικασταί), which would not have been proper for the Areopagus, where the form was ω βουλή (Philippi, *Der Areopag*, p. 32). The punishments inflicted by the Areopagus were—(1.) For wilful murder, death, the execution of which was witnessed by the accuser. It is probable that confiscation of the criminal's property wa included in the sentence, but this point is obscure. His property was certainly confiscated when it happened that he escaped before sentence was pronounced. (2.) For injury with intent (τραῦμα ἐκ προνοίας) the sentence was confiscation of property and banishment, but not for life. If the victim of either of these crimes was a μέτοικος, or alien, the punishment, it has been supposed, was less severe, but of this there is no real evidence. The proceedings, in cases that came before the Areopagus, began, as did all δίκαι φονικαί, with a charge (γραφή) made before the archon king sitting in his chambers in the agora. It was his business to take down the charge and to make such a preliminary inquiry into the facts as would guide him in sending the case for trial. For this purpose he appointed three separate occasions in three successive months, but whether he was contented to search into the facts alleged by the accuser, or whether he examined also the accused, is a point on which there is no evidence. It is only known in general terms that the inquiry was conducted with great care, and, it is not improbable, in presence of members of the Areopagus, who would thus obtain a mastery of the evidence before the trial took place.

The accuser was required to prove his relationship to the murdered person as giving him the right to prosecute; he had to take an oath in pledge of his sincerity, and to denounce the accused. A denunciation (πρόρρησις) having been publicly made, the accused was regarded as polluted, and durst enter neither temple nor market-place on peril of his life. Some have thought that the practice was to make a formal denunciation three times, first at the grave of the deceased, next in the market-place, and then before the archon as just stated (Schömann, *Antiquitates Jur. Pub.*, p. 289), but it is probable that only the last mentioned, if the others were actually made, was regarded as legal. In the fourth month, after determining that the case was to go before the Areopagus, the archon king in his capacity of president of the court laid the case before it. The court sat on the last three days of every month (Pollux, viii. 18). Of the first part of the proceedings (προδικάσιαι) the principal feature was the administration of an oath to the parties and the witnesses; the ceremony consisting in the sacrifice of a wild boar, an ox, or a ram, before which those who took the oath called on the Erinnyes to destroy them and their family if they failed to speak the truth. When the evidence had been gone through (ἀνάκρισις) there followed the δίκη proper, consisting of the speeches. Each party was allowed to speak twice, once, it is said, on each of the first two days, the third day being reserved for judgment. They were charged to avoid everything irrelevant to the issue. After the first speech, the accused might choose voluntary exile unless the charge against him were that of the murder of a parent. In exile, beyond the boundaries of the Athenian state, he was entitled to the full protection of law, and if himself murdered could be avenged as if he had then been a true Athenian citizen. Should the trial go its full length, he could only be convicted by a majority of the judges. If the votes were equal he was acquitted, and when acquitted he offered a sacrifice to the Erinnyes and the other deities of the lower world. When it happened that the person entitled to prosecute had missed the regular occasions of making his charge, it was still competent for him to take the summary proceedings of an ἀπαγωγὴ φόνου, that is, to lay his case before the Eleven who presided over the prisons, and have the case tried by a Heliastic court. But this could not well be done unless the accused had been caught in the act, or failed to give a reasonable account of himself. When the victim survived he himself was the proper prosecutor; but when in the contrary event the task devolved on his relatives, it was necessary for them to be within the prescribed degree of cousinship (ἀνεψιότης), as may be seen from the formula in Pseudo-Demosthenes (*Adv. Macartatum*, p. 1069, § 57), which again has been strikingly confirmed by the decree (Köhler, *Hermes*, ii. p. 27), discovered at Athens in 1843, and setting forth part of the laws of Draco in regard to murder. This decree, inscribed on marble and in a very fragmentary condition, bears date 409–8 B.C. A slave having in the eyes of the law no relatives, could not prosecute the murderer of one of his class, but he could appear against the murderer of his master if empowered in writing to do so before the master's death. The master was the lawful accuser when a slave was murdered, and similarly only the legal patron could appear in the case of a freedman or other who had not the rights of citizenship. The theory of the prosecution being to obtain, as had been the custom from time immemorial, vengeance for the relatives of the deceased, and being therefore more of a religious than political character, it becomes a question whether, in the event of the relatives refusing to prosecute, or of there being no relatives, the state permitted a foul crime to pass unpunished. On this point there is no information.

Besides being a court of justice (δικαστήριον), the Areopagus was also a council (βουλή), empowered to interfere in matters affecting religion and morals, and, previously to the time of Pericles, in the administration of public affairs. With powers of this order honestly exercised, it is not singular that Isocrates (*Areopag.*, 39) in his picture of Athens in the happy times gone by, should point to the action of the Areopagus as one of three great sources of this happiness (*cf.* Plutarch, *Solon*, 22; *Themist.*, 10; and Bockh, *Staatshaushaltung*, i. p. 208). Nor is it against the view of Isocrates that Pericles and his party should have bee opposed to the Areopagites. The mere fact of their being strongly conservative, and of their having the power of opposing, if not with a veto, at least with enormous official influence, his new schemes of administration, would be sufficient excuse. And it appears certain that the scope of the measure proposed by his friend Ephialtes, and carried during the absence of Cimon the conservative leader, was only to withdraw from the Areopagus this power of interference. Its criminal jurisdiction remained as before, though so much would hardly be gathered from the tone of Æschylus in the *Eumenides*, which appeared as a protest, it has usually been thought, at the time. Ἐφιάλτης μόνα κατέλιπε τῇ ἐξ Ἀρείου πάγου βουλῇ τὰ ὑπὲρ τοῦ σώματος, says Philochorus, while Demosthenes (*Adv. Aristocrat.*, p. 644 § 66) states that no tyrant, oligarchy or democracy, had ever ventured to withdraw from that court its jurisdiction in high crimes. Only a passage in a speech of Lysias (*Eratosth.* 30) really favours the opposite view.

Among the many other functions which the Areopagites retained after the measure of Ephialtes were—(1.) those pertaining to religion. They appointed the ἱεροποιοί for the temple of the Eumenides, and took care of the sacred olives (μορίαι), which existed partly in large plantations near the academy, and partly on private lands, such trees being the property of the goddess Athene, against whom it was a crime to injure one of them. The Areopagus could oppose the introduction of new deities or foreign rites, as in the case of St Paul, who had to appear before it (Acts xvii. 19, *ff.*); but it does not seem that it could, as has been assumed, prohibit such a step if once approved of by a public decree. It saw that no object of public sanctity was violated. (2.) In education and morals little positive is known of its action. It seems to have appointed the masters in the gymnasia, and brought to punishment vagabonds and spendthrifts under the law entitled νόμος ἀργίας. (3.) Its business was to see that public spaces were not occupied or built on by private persons, as in the case of Timarchus (Æschines, *Adv. Timarch.*, § 80), who had put it to the public assembly whether the deserted Pnyx might not be built on. Many inscribed bases of statues in Athens, though mostly of a comparatively late date, bear witness that the consent of the Areopagus, if not indispensable, was very frequently obtained for the erection of statues. (4.) It protected the standards of weight and measure from falsification. (5.) It exercised an inquisitorial power, partly *sua sponte* (αὐτὴ προελομένη), and partly by mandate from the public assembly (τοῦ δήμου προστάξαντος αὐτῇ). In the latter case it merely investigated the facts (ζήτησιν ποιεῖσθαι), and laid them before a Heliastic court. Work of this kind, depending as it did on the public assembly, necessarily varied greatly at different times. From about 350 to 320 B.C. it seems to have been of a very grave character. (6.) The Areopagus reviewed the conduct of magistrates and the administration of the laws, a function which was relegated, probably by the measure of Ephialtes, to the Nomophylaces, who, though they do not become conspicuous till the time of Demetrius of Phaleron (317–307 B.C.), had yet existed doubtless long before.

If now it is true that the Areopagites as a criminal court were created and organised by Solon to supersede the Ephetæ in the trial of certain crimes, what is to be said of their origin as a state council (βουλή)? Obviously most of their duties as a council were such as must have grown up gradually upon an institution of very high antiquity, such an institution, for example, as the Homeric βουλὴ γερόντων. Yet there is no direct evidence of the existence of the Areopagus as a council before the time of Solon. It has therefore been suggested that the Areopagitic council appointed by Solon took upon itself the duties of a differently constituted council, which also may have held its sittings on the hill of the Areopagus. This superseded council it was first thought by K. O. Müller consisted of Ephetæ, who, according to the most recent derivation of the name (ἐπὶ and ἔτης = ἔτης, Ϝέτης), were the heads of clans. The opinion of Müller has been adopted by Philippi (*Der Areopag*, p. 208). With less probability Wecklein (*Bericht. d. Münch. Akad.*, 1873, p. 38, *ff.*) had suggested the Naucrari. From the time of Solon, except for the change introduced by Ephialtes, the powers of the Areopagus seem to have remained much the same down to the Roman period, its position in point of respect and influence apparently increasing the longer it continued, though clearly it is too much to say as Cicero does (*De Nat. Deor.* ii. 29, 74) *Atheniensium rempublicam consilio regi Areopagi.* But its constitution had been changed by Plutarch's time, possibly long before. It was then presided over by an ἐπιστάτης with a κήρυξ by his side, and was no longer composed of the retiring archons. The principle of election is not known. (A. S. M.)

AREQUIPA, one of the 18 departments of Peru. It lies along the Pacific from lat. 15° to 17° 20′ S. Its chief productions are silver, alpaca and other wools, sugar, wine, and brandy. The population is stated at 200,000, which is probably in excess. The district is volcanic, and contains several volcanoes, which appear, however, to be mostly extinct. Of these Misti, otherwise known as the Arequipa, one of the most perfectly cone-shaped of mountains, occasionally throws out smoke or vapour. It rises to the height of 20,320 feet above the sea. An eruption of Ubinas, a mountain on the eastern boundary of the department, occurred in 1839.

AREQUIPA, the chief town of the department, stands at the foot of Misti, in the fertile valley of the Chile, 7775 feet above the level of the sea, in lat. 16° 16′ S., long. 72° 31′ W. It is divided into five districts—Santo Domingo, San Francesco, La Merced, San Augustin, and Miraflores—contains 2064 houses, and has a population of about 30,000. In each of the districts there is a monastery and a church; and besides there are three nunneries in the city. The cathedral is quite modern, the former building having been destroyed by fire in 1849. Solidity rather than beauty is the principal characteristic of Arequipan architecture, as might be expected in a city so liable to suffer from earthquakes. These occur with great frequency, and are sometimes of great severity; in 1582, 1609, 1784, and 1868 the city was greatly damaged. In general the streets run at right angles, and are wide and well paved. The better houses are all built in the Spanish style, with two or three courts; the walls are massive, and the ceilings vaulted. The material used is a soft magnesian limestone. The town has a faculty of medicine which rivals that of Chuquisaca in Upper Peru, a university, two academies, a college founded by Grand-Marshal de la Fuente, a public library, established in 1821, two printing-offices, each publishing a small newspaper, an hospital, and a foundling asylum. Arequipa is united to Mollendo on the coast by a railroad completed in 1870, 107 miles in length, nearly the whole of which is over a waterless desert. An iron pipe, which supplies Mollendo with water runs along the line for 85 miles. The railway has now been extended across the Andes, reaching a height of 14,660 feet, to Puno, which is connected with Bolivia by steam navigation across Lake Titicaca.

ARES [MARS], in *Greek Mythology*, the god of war, not, however, of war in its wide sense including campaigns, the disposition and command of forces, but in its more primitive meaning of a fierce encounter between bodies of men. Neither the causes nor the ultimate effects of war were ascribed to him. He was simply a personification of the wild impetuous spirit with which battles were fought,

Ares. From brass coin of the Mamertini. Brit. Mus.

Ares. From brass coin of the Bruttii. Brit. Mus.

and as such he was conceived as the model of a hero, splendidly armed with cuirass, helmet, shield, and spear, swift, of great size (πελώριος), raging (μαινόμενος), murderous (βροτολοιγός), unsatiable of war (ἆτος πολέμοιο). Enyo, the furious war goddess, Eris (Strife), Deimos and Phobos (Dread and Alarm), were usually by his side. Even his mother Hera denounces him (*Iliad*, v. 761) as senseless, and knowing no bounds. It was doubtless only as an illustration of the habitual strife between Hera and Zeus that Ares was accounted their son. When wounded by Diomedes assisted by Athena (*Iliad*, v. 853, *ff.*), he fell with a noise like that of nine or ten thousand men in battle; and again (*Iliad*, xxi. 400, *ff.*), when Athena wounded him with a stone, he fell, and covered with his fall seven acres of ground. On this latter expression it is to be observed, that, while it conveys a picture of broad-strewn carnage consistent with the usual character of Ares, it suggests also, from the measurement given, thoughts of the destruction of cultivated land in war, the more so when taken in connection with the story of Otus and Ephialtes, which reads in the *Iliad* (v. 385) like a reminiscence from an earlier time, when war was the dread of the husbandman. These two giants, sons of Aloeus, the planter, born very small, but grown by being fed on grain to immense size, and occupied, as their names imply, with husbandry (Otus = ὠθέω, and Ephialtes = ἐπιάλλομαι), had seized Ares and confined him in a large brazen jar for thirteen months, so that for one year there was entire peace over the fields. If, as is not improbable, the first conception of a war god originated in connection with invasion from non-Hellenic tribes, it would be natural to regard him perhaps more as a ruthless destroyer of fields than of human life, and equally natural that this view of his character should die out when war became, so to speak, a trade, as it had become by the time of the Iliad. Even then he was still recognised as a god whose home was among the warlike Thracians (*Iliad*, xiii. 298; *Odyssey*, viii. 361). This, it is true, may have been nothing more than another instance of the Greek tendency to assign a northern or Hyperborean home to deities in whose character something analogous to the stormy elements of nature was found. On the other hand, it appears that the Thracians and Scythians in historical times (Herodotus, i. 59) worshipped chiefly a war god and that certain Thracian settlements, formed in Greece in prehistoric times, left behind them traces of the worship of a god whom the Greeks called Ares. At Thebes, for instance, had been such a settlement, and there, above all the rest of

Greece, were afterwards found the oldest traditions of the worship of Ares, and that not altogether in the character of a war god. The fountain of Ares guarded by a dragon, and the legend of the Spartæ, who sprang from a field sown with dragon's teeth, seem rather to symbolise some destructive influence in nature, such as that of the sun in summer scorching the fields. That influence of this kind was ascribed to the Thracian god follows from the identification of him with the Sabine and Roman Mars, to the latter of whom the Arval brethren in Rome made annual sacrifice of a red dog to avert the calamity of the ripe grain taking fire. Apollo is the god who in Greek mythology, as we know it, discharged such functions. But it is argued that in this matter he may have superseded Ares, who on assuming the Thracian character of war god may have gradually resigned his original office. In one of the Homeric hymns Ares is described as a sun god who makes courage and valour stream into the hearts of men, and again, Æetes, king of Colchis, though a son of Helios, was yet the guardian of the grove of Ares, where was the golden fleece. Meleager, whose valour was displayed against the Calydonian boar, a pest to the fields of Ætolia, was a son of Ares and the fostering nymph Althæa. Œnomaus was a son of Ares and a daughter of the river god Asopus. The dog, which had originally referred to the dog star, remained his symbol, but could only be accounted for by the constant presence of that animal on battle-fields. From the destruction of crops by summer heat to similar destruction by war-like invasion seems a natural step. The next step was to take the point of view of the invader, and to magnify the exploits of war. By the time of Homer this had been done effectually, though traces of an older form of belief remain both in the *Iliad* and *Odyssey*. Besides those already mentioned, there is the remarkable incident in the *Odyssey* (viii. 266, *ff.*) where Hephæstos, informed by Helios of the infidelity of his wife Aphrodite with Ares, captures them together in a net, and there holds them for the ridicule of the gods. In what appears to be a very early development of her character, Aphrodite was a war goddess, and was styled Areia. But it is scarcely possible that a phase of character shared also, for example, by Athena, could have suggested such a relation between Ares and Aphrodite, though Hesiod's statement (*Theogony*, 934) that Deimos and Phobos were their offspring points in that direction. Again, though Ares and Aphrodite were worshipped together at Thebes, it is not known that they were worshipped there as deities of war. Harmonia, the wife of Cadmus, the founder of that town, was regarded as their daughter. Possibly the connection originated in some other approximation between Ares and Aphrodite in an earlier form of their worship. Women were excluded from the festivals of Ares except at Tegea, in Arcadia, where he was called γυναικοθοίνας. But that exception appears to have been based only on an instance in which that town was successfully defended by its women. While honoured here and there with festivals and sacrifice, as at Sparta, where young dogs, and apparently once men, were offered to him under his title of Enyalios and Theritas, there were yet wanting in his case those local beliefs and traditions which gave vitality to the worship of a god. Next to Thebes, already mentioned, it was at Athens that this vitality obtained most, through the legend attaching to the Areopagus (Αρειος πάγος). The nymph Agraulos had born him a daughter Alcippe, whom Halirrhotius, a son of Neptune, had seized with violence, and for this was slain by Ares, who was tried by a council of the gods sitting on the Areopagus and acquitted. At the foot of the Areopagus was a temple of Ares, with a statue of the god from the hands of Alcamenes. To judge now of the fluctuation in the conception of Ares from works of art, it is found that previous to the 5th century B.C., he was figured bearded, grim, and heavily armed. From that time, apparently under the influence of Athenian sculptors, who had to render his form in some harmony with their local war goddess Athena, he was conceived as the ideal of a youthful warrior, and for a time associated with Aphrodite and Eros, as in the group of the villa Borghese at Rome, where Eros plays with his weapons, and in many other groups of Ares and Aphrodite in marble and on engraved gems of Roman times. But before this grouping had recommended itself to the Romans, with their legend of Mars and Rhea Silvia, the Greek Ares had again become under Macedonian influence a bearded, armed, and powerful god. The Romans, however, though they readily adopted the Greek Mars and Venus, yet retained the former deity in his native character as a god representing the influence of the sun on cultivated fields, resembling the Mamers of the Mamertines in Sicily, with a wolf as his symbol (Conze, *Heroen und Götter Gestalten*, p. 22, Vienna, 1874; Preller, *Griechische Mythologie*, i. pp. 251–259; Welcker, *Griechische Götterlehre*, i. pp. 413–424).

(A. S. M.)

ARESON, JON (or HANS), a poet, and the last Roman Catholic bishop in Iceland, was born in 1484. He endured many privations in his youth, and at the age of twenty took holy orders, and was attached as priest to the parish of Helgastad. Here he was taken under the protection of Gottskalk, bishop of Holum, who twice sent him on missions to Norway. He acquitted himself so well that in 1522 he was appointed successor to Gottskalk. To many his election was displeasing, chiefly on account of his ignorance of Latin; and Ogmund, bishop of Skalholt, the other diocese, drove Areson with violence from his bishopric. He was reinstated in 1524, and spent some rather stormy years till 1540, when Frederic III., king of Denmark, wrote to the bishops of Iceland desiring them to take measures for the introduction of Lutheranism. This Areson declined to do, and he even denied the king's power as head of the church. The greater part of the island, however, became Protestant. In 1548 the Lutheran bishop of Skalholt died, and Areson made an armed excursion into his successor's territory. For this he was in 1549 declared an outlaw. He again sent an expedition against Skalholt, and captured the bishop, whom he treated with indignity. In 1550 his forces were defeated; he was taken, and executed along with two of his sons. Areson is celebrated as a poet, and as having been the first to introduce printing into Iceland. Several of his poems are collected by Harboe in his *History of the Reformation in Iceland.*

ARETÆUS, a Greek physician of Cappadocia, who lived, according to some, in the reign of Augustus; according to others, under Trajan or Hadrian. He was one of the class of Pneumatic physicians, who made the heart the seat of life and of the soul. He wrote, in the Ionic dialect, several treatises on acute diseases and other medical subjects, some of which are still extant. The best editions of his works are—that of Boerhaave, in Greek and Latin, with notes, 1731; that printed at Oxford in 1723, in folio; and those by C. G. Kühn, 1828, and Ernerius, 1847.

ARETHUSA, a fountain at Syracuse, in Sicily, famed among the ancients for the abundance of its waters and the number of its fishes, but still more so for the connection which was fabled to exist between it and Alpheus, the river of the Peloponnesus, "who stole under seas to meet his Arethuse." According to the anthropomorphic legend, Arethusa was a daughter of Nereus and Doris, who was changed into the fountain by her mistress Diana (Artemis), to deliver her from the pursuit of her lover Alpheus. There is still a copious supply of water in the modern fountain, but the taste is brackish, and it can only be used for washing; while the fish are no longer to be found. There was a fountain of the same name in Ithaca (Homer), and another at Chalcis in Eubœa, which supplied the city with water, but, according to Leake, has now disappeared. There was also a lake Arethusa, through which the Tigris flowed, identified by Ritter with L. Nazuk.

Arethusa was also the name of two cities: Arethusa in Macedonia, famous for the tomb of Euripides, and Arethusa in Syria (*Rastan*), which gives its name to Marcus, a bishop who was persecuted by the Arethusans, and is honoured as a martyr by the Greek Church.

ARETINO, Pietro, an Italian writer of the 16th century, was born in 1492 at Arezzo in Tuscany, from which place he took his name. He is said to have been the natural son of Luigi Bacci, a gentleman of the town. He received little education, and lived for some years poor and neglected, picking up such scraps of information as he could. When very young he was banished from Arezzo on account of a satirical sonnet which he composed against indulgences. He went to Perugia, where for some time he worked as a bookbinder, and continued to distinguish himself by his daring attacks upon religion. After some years' wandering through parts of Italy he reached Rome, where his talents, wit, and impudence commended him to the Papal Court. This favour, however, he lost in 1523 by writing a set of obscene sonnets, to accompany an equally immoral series of drawings by the great painter, Julio Romano. He left Rome and was received by John de Medici, who took him to Milan and introduced him to Francis I. He gained the good graces of that monarch, and received handsome presents from him. Shortly after this Aretino attempted to regain the favour of the Pope, but, having come to Rome, he composed a sonnet against a rival in some low amour, and in return was assaulted and severely wounded. He could obtain no redress from the Pope, and returned to John de Medici. On the death of the latter in December 1526, he withdrew to Venice, where he afterwards continued to reside. He spent his time here in writing comedies, sonnets, licentious dialogues, and a few devotional and religious works. He led a profligate life, and procured funds to satisfy his needs by writing sycophantish letters to all the nobles and princes with whom he was acquainted. This plan proved eminently successful, for large sums were given him, apparently from fear of his satire. So great did Aretino's pride grow, that he styled himself the "divine," and the "scourge of princes." He died in 1557, according to some accounts by falling from his chair in a fit of laughter caused by hearing some indecent story of his sisters. The reputation of Aretino in his own time rested chiefly on his satirical sonnets or burlesques; but his comedies, five in number, are now considered the best of his works. His letters, of which a great number have been printed, are also commended for their style. The dialogues and the licentious sonnets have been translated into French, under the title *Académie des Dames.*

AREZZO, the ancient Arretium, a Tuscan city on the Chiana (*Clanis*), which is now an affluent of the Arno, but formerly flowed into the Tiber. Arretium was one of the twelve cities of the ancient Etruscan Confederation, and continued after its incorporation with the Roman dominion to be a highly important military post. Having sided with Marius in the civil war, the Aretines were deprived by Sulla of their Roman citizenship; but the city received a colony under Augustus, and seems to have had a peculiar municipal constitution. In the time of Pliny it was known for its pottery, and many specimens of the bright red ware, with ornaments in relief, differing from the productions of Southern Etruria, have been preserved to the present day. Among the relics that have been discovered here are the bronze statues of Minerva and the Chimæra, now in the Florentine Gallery. In modern history Arezzo is chiefly remarkable for the obstinate opposition it maintained against the pertinacious encroachments of the Florentines, to whom, however, it had finally to submit. It is now a clean, well-built, well-paved, and flourishing town of 10,000 inhabitants, the seat of a bishop and a prefect, with a theological seminary, a surgical school, a library, and a museum. In its cathedral are the tombs of Guido Tarlati, its warlike bishop, who died in 1327, Gregory X. (1276), and Redi the naturalist (1698). Few cities can show such a list of remarkable men as Arezzo—Mæcenas (?), Guido, famous for his musical discoveries, Guittone the poet, Petrarch, Leonardo Bruno the historian, Cesalpini the botanist, Margheritone and Spinello the painters, Alberghotti the jurist, Pope Julius III., Pietro Aretino the satirist, Vasari the author of *Lives of the Artists*, Redi already mentioned, Fossombroni the mathematician and engineer.

ARGÁM, a village of Haidarábád, in the Nizám's dominions, situated in 21° 2′ N. lat., and 77° 2′ E. long., 40 miles south-west of Elichpur, and 135 miles north-east of Aurungábád. The village is rendered memorable as the site of an action which took place on the 28th November 1803 between the British army, commanded by Major-General Wellesley (afterwards Duke of Wellington), and the Marhattás under Sindhiá and the Rájá of Berar, in which the latter were defeated with great loss. A medal struck in England in 1851 commemorates the victory.

ARGELANDER, Friedrich Wilhelm August, a distinguished German astronomer, was born at Memel, 22d March 1799; and died at Bonn, 17th February 1875. He studied at the university of Königsberg, where his attention was attracted to the study of astronomy by Bessel, whose assistant he became in 1821. In the following year he published an essay on the path of the great comet of 1811, the period of which he determined with great accuracy. In 1823 he was made superintendent of the observatory at Abo; and in 1832 was transferred to the university of Helsingfors, where he remained for five years. In 1837 he published an admirable essay upon the proper motion of the solar system, and in the same year was appointed professor of astronomy at Bonn, where he spent the remainder of his life. Argelander's fame rests principally on the extensive and accurate observations he undertook in continuation of the plan laid down by Bessel. His results were published in the *Observationes Astronomicæ Aboæ factæ*, 3 vols., 1830–32; DLX *Stellarum Fixarum Positiones Mediæ*, 1835; *Durchmusterung des nörd. Himmels zwischen* 45° *und* 80° *nördl. Breite*, 1846; and in the *Sternverzeichniss*, containing upwards of 210,000 stars, in the 3d and 4th vols. of the *Astron. Beobacht. auf der Sternwarte zu Bonn.* The *Neue Uranographie*, 1843, and the *Atlas des nördl. gestirnten Himmels*, 1857, are also valuable works. For several years before his death, Argelander was engaged in observations on stars of variable magnitude and brilliancy, and the results of his labours will probably be put forth in a collected form.

ARGENSOLA, the name of two Spanish poets, brothers, who are sometimes called the "Spanish Horaces." The elder, Lupercio Leonardo y Argensola, was born in 1565 and died in 1613. He was educated at the universities of Huesca and Saragossa, and became secretary first to his patron, the duke of Villahermosa, and afterwards to the ex-Empress Maria of Austria. In 1599 he was made historiographer of Aragon, and a few years later historiographer royal. In 1610 he accepted the office of secretary to the Count of Lemos, then viceroy of Naples, at which place he died. His works consist of three tragedies, highly praised by Cervantes, and lyric poems, published along with those of his brother. Some historical writings of his have not been published. The younger brother, Bartolomeo Leonardo, was born in 1566 and died in 1631. He entered the church, and in 1588 received the rectory of Villahermosa. He afterwards acted as chaplain to the Empress Maria. Sometime after the death of his brother he succeeded to the office of historiographer. His principal works are—a history of the Conquest of the Molucca Islands (*Conquista de las Islas Molucas*, 1609), which has been translated into English, a continuation of Zurita's *Annals of Aragon*, and a translation from the English, called *Regla de Perfeccion*. His fame rests chiefly on his poems, which are highly esteemed by competent critics.

ARGENTAN, a town in the department of Orne, in France, situated in the midst of a fertile plain at the junction of the Ure and Orne, about 31 miles from Alençon. It is a sub-prefecture, and the chief town of an arrondissement, and has an ancient castle, now used as a court-house and prison, several important churches, and a handsome town-house. Its manufactures are a coarse kind of lace called after its name, gloves, leather, and fine cloth. Cattle and horses are reared. Argentan was a viscountship from the 11th century downwards; it has been often taken and destroyed; and during the religious wars it remained attached to the Catholic party. François-Eudes de Mézeray, the historian, was born at Rie, in the neighbourhood. Population in 1872, 5725.

ARGENTEUIL, a market-town of France, in the department of Seine-et-Oise, and arrondissement of Versailles, on the Seine, in lat. 48° 56′ N., long. 2° 15′ E. It gathered round a monastery, which, dating from 656 A.D., was by Charlemagne changed into a nunnery, afterwards famous for its connection with Heloise, and on her expulsion in 1129, was again turned into a monastery. Francis I. surrounded the town with walls and a ditch. The Chateau du Marais was once possessed by Mirabeau, and the parish church dates in some portions from the time of Clovis. Vinegar and an indifferent kind of wine are manufactured, and in the neighbourhood there are fine quarries of gypsum. Population, 8176.

ARGENTINE REPUBLIC

Plate XXV.

THE ARGENTINE REPUBLIC comprises the greater part of what was formerly the Spanish viceroyalty of Buenos Ayres. On the separation of the country from Spain the remainder of the viceroyalty seceded from the authority of the government established at Buenos Ayres, and formed the three important republics of Bolivia, Paraguay, and the Banda Oriental del Uruguay, commonly called either the Oriental Republic or Uruguay. The city of Buenos Ayres, the capital of the province of the same name, then became the seat of the national government of the United Provinces of the Rio de la Plata,—so named in the treaty with England, by which their independence was recognised, and since termed the Argentine Republic. Including the Indian tribes, who are in almost undisputed possession of half its territory, the country does not contain half so many inhabitants as the city of London, though it extends over an area as great as all Central and Western Europe combined; and the fertility of its vast plains, together with the yet undeveloped wealth of its mineral resources, indicate that it is well able to sustain as numerous a population as that of the part of Europe just alluded to. Its extent in latitude is greater than that of any other existing country, if we except the comparatively useless foreign regions of British America and those of the Russian empire, though it only slightly exceeds that of the comparatively narrow slip of land which forms the neighbouring Republic of Chili.

Boundaries.

It is bounded on the W. by Chili; on the S. by the Strait of Magellan; on the E. by the Atlantic Ocean, the Oriental Republic, the Empire of Brazil, and the Republic of Paraguay; and on the N. by the Republic of Bolivia. The boundary to the W. is formed by the mountain chain of the Andes. The southern limit is at present a question in dispute with the Government of Chili, who claim the entire extent of the Strait of Magellan; but it is probable that the Argentine Government will make good its claim to the eastern portion. The broad stream of the Uruguay below its tributary, the Guarey, or Cuareim, divides it from the Oriental Republic, except that the small but important island of Martin Garcia, close to the Oriental shore of the Uruguay at its junction with the Parana, belongs to the Argentine Republic. The boundary with Brazil is then formed by the Uruguay and its tributary, the Pepiri Guazu, from the head waters of which it crosses the Sierra de los Missiones to the head waters of the San Antonio Guazu, the course of which it follows, and then that of the Iguazu, or Rio Grande de Caritiba, an important tributary of the Parana. The Parana, down to its junction with the Paraguay, and the latter upwards as far as the mouth of the Pilcomayo, form the boundary with the Republic of Paraguay. South of the 22d degree of latitude the country between the Pilcomayo and the Paraguay is disputed by the Argentine Republic and Paraguay. The boundary with Bolivia lies along the 22d degree of latitude between the Pilcomayo and the Vermejo, and then, leaving important tributaries of the latter to Bolivia, it follows the course of that river to its source, whence it takes a devious course westwards among the mountains which form spurs to the Andes. On reaching the latter it follows the main chain southwards to latitude 25° 30′, where it passes to a more westerly ridge of the Andes on which the boundaries of the three neighbouring republics unite. The boundary we have described with Bolivia cannot be considered as permanently settled; and the boundary between Bolivia and Paraguay to the north of the Argentine Republic has not been determined. The boundary questions with all these republics are in an unsatisfactory state.

Physical geography. Plains

The most remarkable feature of the country is its plains, which may be said to extend over more than three-fourths of it. The plains of Patagonia in the south, the Pampas across the extending central part of the country, and the Chaco in the north-east, have no very definite natural boundaries. The two latter are, in fact, the same continuous formation, in which a slight undulation divides the streams of the Chaco, which join the Parana, from those of the Pampas, which either flow into the Atlantic south of the mouth of the latter river, or disappear by absorption into the soil, and evaporation as they spread over the plains. The best parts of these plains are covered with a rich alluvial soil from 3 to 6 feet in thickness, formed by the constant decaying of the luxuriant vegetation which grows upon it, and this soil rests upon a sedimentary deposit of earth, which appears to have been scoured away from the Andes and the high lands of the central part of the continent. A great part of Patagonia and the western Pampas consists of gravel and coarse detritus from the Andes, and, though apparently sterile, only requires irrigation to become productive. Other parts of the plains are dry, saline wastes or brackish marshes, which probably mark the former position of an inland sea. Excepting the hills in the south

Mountains. of the province of Buenos Ayres and those of Cordova, the mountain districts of the country consist of the eastern slope of the gigantic range of the Andes and its branches, which latter make all the north-western part of the country a mountainous region. The great chain of the Andes consists of a confused mass of broken and contorted strata, piled upon an elevated ridge of granite, through which numerous volcanoes, many of them still active, have ejected vast quantities of lava and scoriæ. Along most parts of the great mountain chain there are three subsidiary and more or less parallel ridges, between which fertile valleys are formed in many places, whilst in other parts the separation between them is not very clearly defined. In the north-west the boundary with Bolivia lies along the most eastern of the ridges just mentioned, so that the valleys to the west of it are within that republic, but the boundary with Chili lies along the western ridge, so that the central and eastern ridges, with the fine valleys which lie between them, belong to the Argentine Republic. The great chain of the Andes, as described by Mr Evan Hopkins, who made extensive explorations in various parts of it, is formed of innumerable varieties of granite, gneiss, schists, hornblende, chloritic slates, porphyries, &c., and these rocks alternate with each other in great meridional bands. The crystalline rocks follow no particular order in the alternation. For miles only granite and gneiss are found, and again schist, quartz, gneiss, &c., intervening. The whole of the crystalline rocks, especially the micaceous variety, pass insensibly from the crystalline to the laminated structure. We have first the granite base, in which the crystals are somewhat confusedly mixed; these gradually become arranged upwards into parallel lines, and the rock is then called gneiss; by degrees the felspar is decomposed, and the mass becomes schistese, with enclosed veins of the predominating element of the compound below. This is the general character of the primary structure of the Andes, and upon it there are many bits of sandstones, limestones, &c., especially on the eastern chain.

Darwin's researches. The most careful and elaborate researches into the geological conformation of the country were made by Mr Darwin, who published the results in his work on the geology of South America. He points out evidences of a gradual upheaval of the plains of Patagonia and the Pampas, to the extent of 400 feet in the southern part of the former, and 100 feet in the latter district. The Pacific and Atlantic Oceans were once connected through what is at present the basin of the Santa Cruz river, in latitude 50° S. This latter district appears to have been upheaved at least 1400 feet before the period of the gradual upheaval above mentioned, as indicated by the present position of gigantic boulders, which have been transported on icebergs 60 and 70 miles from their parent rock. The enormous layers of gravel and sand, on the plains and even on the hills of eastern Patagonia, give evidence of its having at one time formed the bed of an ocean which rolled against the Andes or intervening ranges of mountains. The characteristic feature of the plains of Patagonia is gravel, whereas that of the Pampean formation, which includes the Chaco, is earth which, according to Mr Darwin's lucid arguments, has been deposited in the form of sand in the estuary of the River Plata, the position of which has been continually changing in consequence of the gradual upheaval of the country. This formation extends to the south-west and north-west from the present estuary, over an area at least 750 miles long and 400 miles broad, and the thickness of the deposit is from 30 to 100 feet. The hills of Tapalquen, Tandil, and Vulcan, composed of unstratified granular quartz, project through the eastern part of this Pampean formation. The higher range of the Sierra Ventana further south is also quartz. South of the Sierra Ventana, for a distance of 380 miles, crystalline rocks are seldom if ever met with on the east coast; and beyond that a porphyritic formation is found resembling the lowest stratified formation of the Andes.

"The highest peaks of the Cordillera," says Mr Darwin, "appear to consist of active, or more commonly, dormant volcanoes—such as Tupungato, Maypu, and Aconcagua, which latter stands 23,000 feet above the level of the sea, and many others. The next highest peaks are formed of the gypseous and porphyritic strata, thrown into vertical or highly inclined positions. . . . This grand range has suffered both the most violent dislocations, and slow, though grand, upward and downward movements in mass: I know not whether the spectacle of its immense valleys, with mountain masses of once-liquefied and intrusive rocks now bared and intersected, or whether the view of those plains, composed of shingle and sediment hence derived, which stretch to the borders of the Atlantic Ocean, is best adapted to excite our astonishment at the amount of wear and tear which these mountains have undergone."

We commend Mr Darwin's work to the attention of readers desirous of becoming better acquainted with the geological conformation of the Argentine Republic.

Climate. The great extent of this country in latitude makes its climate range through all diversities of temperature from that of Northern Europe and Canada to that of Egypt and Arabia. The climate of Southern Patagonia is less intemperate than that of Labrador at the same distance from the equator in the northern hemisphere, but colder than the Atlantic shores of Europe in the same latitude. As the difference of climate in the same latitude in the northern hemisphere is in a great measure attributed to the fact of the warm water from the equatorical regions drifting towards the shores of the north of Europe, whilst the cold water from the Arctic regions is constantly flowing southwards along the coast of Labrador, so also the intermediate nature of the climate of Patagonia is doubtless, in some measure, due to the tendency of the cold water of the Antarctic regions to flow northwards through the central parts of the Atlantic Ocean, as pointed out by Maury, thus throwing the warm water southwards along the coasts of Brazil and Patagonia. Argentine Patagonia might, not inaptly, be termed the Sweden, and Chilian Patagonia the Norway of the southern hemisphere. In the north of Patagonia and the southern part of the province of Buenos Ayres the climate, as regards temperature, resembles that of England; and northwards of this is the broadest part of the republic, which contains the city of Mendoza in the far west, and Buenos Ayres in the east, and enjoys one of the finest climates in the world, rivalling that of Southern France and Northern Italy. North of this the summer heat becomes too oppressive, and in the extreme north the climate is thoroughly tropical. In some parts of the north-west the altitude of the country gives it a cooler climate than that of the Chaco in the same latitude. Along the Argentine slopes of the Andes and the adjacent country the climate is remarkable for its dryness, because the prevalent westerly winds lose the moisture which they bring from the Pacific before crossing the mountains. This peculiarity is most marked in the southern part of the continent, where Chilian Patagonia is deluged with almost incessant rain, whilst Argentine Patagonia is dry and arid. In the east, as at Buenos Ayres, there is more rain, which, with southerly winds and occasional north-westerly storms, is often very heavy. The oppressive humidity which is characteristic of the northerly and north-easterly winds forms the most disagreeable and unhealthy weather experienced in that part of the country. The climate of Cordova, and also that of some of the more westerly districts, is found very suitable for consumptive patients.

History. The first Europeans who visited the River Plate were a party of Spanish explorers in search of a south-west passage to the East Indies. Their leader, Juan Dias de Solis, landed, in 1516, with a few attendants on the north coast

between Maldonado and Monte Video, where, according to Southey, they were treacherously killed, and then cooked and eaten by the Charrua Indians in sight of their companions on board the vessels. The survivors at once abandoned the country and returned to Spain, reporting the discovery of a fresh-water sea. In 1519 Magalhaens, in the service of the king of Portugal, entered this fresh-water sea, or Mar Dulce, as it was then called, but finding no passage to the west, he left it without landing, and then achieved his famous voyage to the East Indies, passing through the strait which bears his name in 1520. After this Sebastian Cabot, already a renowned navigator, who, in the service of Henry VII. of England, had attempted to find a north-west passage to the East Indies, entered the service of Charles I. of Spain, and sailed in command of an expedition fitted out for the purpose of colonising the discoveries of Magalhaens in the East Indies. He, however, entered the River Plate in 1527, and anchored off the present site of the city of Buenos Ayres. He then ascended the Parana, and established a settlement, named San Espiritu, among the Timbú Indians in Santa Fé; and he succeeded in bringing that tribe of Indians to friendly terms with the colony. He continued the ascent of the Parana as far as the cataracts in Missiones, and afterwards explored the Paraguay, from which he entered the Vermejo, where his party suffered severely in a savage fight with the Agaces, or Payaguá Indians. Of this tribe a subdued remnant now lives on the delta of the Pilcomayo, opposite Asuncion, amalgamating neither with the Spaniards nor with the wild Guaycurus of the surrounding parts of the Chaco. The profusion of silver ornaments worn by these Indians, as well as by the Timbus and Guaranis, led him to give the name of Rio de la Plata, or Silver River, to the splendid stream which he had thus far explored. This name, rendered in English *River Plate*, is now applied only to the estuary below the junction of the Paraná and Uruguay. One of Cabot's lieutenants, detached on a separate exploring expedition up the Uruguay, was killed, together with a great part of his crew, by the Charrua Indians. And subsequently at San Espiritu, an attempt of the chief of the Timbus to obtain possession of one of the Spanish ladies in the settlement led to a treacherous massacre of the garrison. Before this latter occurrence Diego Garcia arrived in the river with an expedition fitted out in Spain, for the purpose of continuing the explorations commenced by De Solis; and Cabot returned to Spain, where he applied to Charles I. for the means of opening communications with Peru by way of the Vermejo. But the resources of the king were absorbed in his struggle as emperor (under the name of Charles V.) with Francis I. of France, so that he was obliged to leave the enterprise of South American discoveries to his wealthy nobles. In August 1534 Mendoza left Cadiz for the River Plate at the head of the largest and wealthiest expedition that had ever left Europe for the New World. In January 1535 he entered the River Plate, where he followed the northern shore to San Gabriel, and then crossing the river, he landed on the Pampas. The name of Buenos Ayres was given to the country by Del Campo, who first stepped ashore where the city of that name now stands, and where, on the 2d February, the settlement of Santa Maria de Buenos Ayres was founded; the smaller vessels having been safely harboured in the Riachuelo, half a league south of the settlement. Mendoza's captains then explored the country between Paraguay and Peru, in which latter country Pizarro had, in 1535, founded the city of Lima. Of one of these expeditions consisting of 200 men, who left Paraguay in February 1537, and are said to have reached the south-east districts of Peru, under Ayolas, every man was killed by the Payaguá Indians in the northern part of the Chaco whilst the expedition was returning laden with plunder. Ayolas had, on his way up the river, built and garrisoned a fort named Corpus Christi among the Timbus in Santa Fé, near the deserted settlement of San Espiritu; and in Paraguay, after three days' fighting with the Guaraní Indians, as narrated by Du Graty, he had, on the 15th August 1536, established a settlement where the city of Asuncion now stands. In the meantime the settlement of Buenos Ayres was attacked and burnt by the Indians; and after terrible sufferings from famine as well as attacks of the Indians, jaguars, and pumas, the Spaniards abandoned the place on the arrival of a fresh expedition from Spain, in company with which they ascended the river, first to Corpus Christi, and then to Asuncion, where, in 1538, Irala was elected captain-general. In 1542 Buenos Ayres was re-established by an expedition sent out from Spain for the purpose under Cabesa de Vaca. This able leader landed at Santa Catherina, in Brazil, and marched overland to Asuncion, from which he sent vessels to join the new expedition at Buenos Ayres, reaching that place, according to Southey, just in time to save the new comers from extermination by the Indians. Here the Spaniards again found themselves unable to withstand the incessant attacks of the savages, and the place was a second time abandoned on the 3d February 1543. At Asuncion the Spaniards were more successful in establishing themselves among the Guaraní Indians, who, after much severe fighting, finding themselves unable to vanquish the Spaniards, made alliance with them both offensive and defensive, and also intermarried with them. The events which transpired at Asuncion belong, however, to the history of Paraguay. In 1573 Garay, at the head of an expedition despatched from Asuncion, founded the city of Santa Fé near the abandoned settlements of San Espiritu and Corpus Christi. The expulsion of the Spaniards from the latter place had, according to the *Historia Argentina*, resulted from a wanton attack made by them on the Caracara Indians, slaughtering the men, and taking the women captive,—a mode of procedure which all Pampa Indians adopted, and have ever since acted on. It is unfortunate, both for the Indians and for the Spaniards, that the bold *conquistadores* were not always under the guidance of such high principled men as Cabot and Cabesa de Vaca. In 1580, when the new colony had been firmly established, Garay proceeded southwards and made the third attempt to establish Buenos Ayres, under the name "Cuidad de la Santissima Trinidad, Puerto de Santa Maria de Buenos Ayres;" and notwithstanding the determined hostility of the Querandi Indians, who were encouraged by the success of their two preceding wars, the Spaniards succeeded in holding the place. The settlement prospered, and the cattle and horses brought from Europe multiplied and spread over the plains of the Pampas. Whilst the Spaniards of the River Plate were thus engaged, Pizarro had effected the conquest of Peru; and his lieutenant, Almagro, had extended the conquest to the south of Chili, from which, in 1559, Hurtado de Mendoza crossed the Andes, and, having defeated the Araucanian Indians, founded the city of Mendoza. It is interesting to observe, that up to the present day the giant chain of the Andes has been a less effective barrier to trade than the rich plains of the Pampas. This state of affairs will, however, now soon be altered by the railway, for which Mr Clark has just obtained a concession, direct from Buenos Ayres to Mendoza. In 1550 the Spaniards from Peru entered the north-western provinces by way of Catamarca, and founded the city of Tucuman in 1565, and that of Cordova in 1573. It was only in 1873, just three hundred years after the cities were founded, that the boundary between the jurisdiction of Cordova and that of

Santa Fé was determined by the intervention of the national Government. In 1620 Buenos Ayres was separated from the authority of the Government established at Asuncion, and was made the seat of a Government extending over Mendoza, Santa Fé, Entre Rios, and Corrientes, but at the same time remained, like the Government at Asuncion and that of Tucuman, which latter included Cordova, subject to the authority of the viceroyalty of Peru.

After the vast expenditure of blood and treasure which was incurred by the Spaniards in establishing themselves on the River Plate as just described, the restrictive legislation of the home Government became a more effective hindrance to the development of its resources and the spread of civilisation over the country than the hostility of the Indian tribes. Cabot had urged the feasibility of opening an easier channel for trade with the interior of Peru through the River Plate and its tributaries than that by way of the West Indies and Panama; and, now that his views seemed about to succeed, the interests of the trade, which had in the meantime been established by the northern route, combined to crush the threatened development of that of the River Plate. Spanish legislation endeavoured to exclude all European nations except Spain from the trade by way of the West Indies, and to prevent any trade from being transacted by way of the River Plate, thus enacting most flagrant injustice towards the people it had encouraged to settle in the latter country. The hardy pioneers of European civilisation in these regions so far overcame the pernicious influences which acted upon Spanish legislation, that in 1602 they obtained permission to export two shiploads of produce a year. But, to prevent internal trade with Peru, a custom-house was established at Cordova, to levy a duty of fifty per cent. on everything in transit to or from the River Plate. In 1665 a relaxation of this system was brought about by the continued remonstrances of the people; and in 1774 free trade was permitted between several of the American posts. In 1776, with a view to better maintaining the country against the encroachments of the Portuguese in their colonies in Brazil, Buenos Ayres was decreed the capital of a viceroyalty, with jurisdiction over the territories of the present republics of Bolivia, Paraguay, Uruguay, and the Argentine Confederation. All this country was then opened to Spanish trade, even with Peru, and the development of its resources, so long thwarted, was allowed comparatively free play. From this time a succession of viceroys exercised jurisdiction over the whole of these territories. Velasco, however, was made governor of the semi-civilised Indians in the Jesuit settlements of Missiones on the Rivers Parana and Uruguay, subject only to the direct authority of the home Government; and in 1806 he became also governor of the province of Paraguay, under the authority of the viceroyalty of Buenos Ayres, and these offices he still held when the independence of the country was declared.

The authority of the viceroys was interrupted in the lower part of the River Plate during the wars between England and Spain. On the 27th June 1806 General Beresford landed with a body of troops from a British fleet under command of Sir Home Popham, and obtained possession of the city of Buenos Ayres. The viceroy, Sobremonte, retired to Cordova, where Liniers collected an army from all parts of the country, with which, on the 12th August, he assaulted the city, and Beresford with his troops surrendered. In the meantime Sir Home Popham had taken Maldonado; and in February 1807 Sir Samuel Auchmuty stormed and took the city of Monte Video. In May 1808 General Whitelock, with 8000 men, endeavoured to regain possession of Buenos Ayres; but the inhabitants had made great preparations for resistance, and as all the houses were at that time built with their windows opening on the streets, protected with strong iron railings like prison bars, and with flat roofs, each one was of itself a fortress: so that after suffering terrible slaughter in the long straight streets ot the city, the invading army capitulated, agreeing to abandon both banks of the River Plate within two months. Whitelock was brought before a court-martial appointed to inquire into the cause of the failure of the enterprise entrusted to him; the indignation excited against him in England. in consequence of his want of success, was as great as that excited on the River Plate against the viceroy, Sobremonte, in consequence of the first success of the English. The events which we have narrated tended to give self-confidence to the people of Buenos Ayres, who, on applying to the home Government for assistance against the English, had been told that they must protect themselves. But the disturbances which ultimately led to the separation of the country from Spain were initiated by the refusal of the Argentines to acknowledge the Napoleonic dynasty established at Madrid. Liniers, who was viceroy on the arrival of the news of the crowning of Joseph Buonaparte as king of Spain, was deposed by the adherents of Ferdinand VII.; and on the 19th July 1809, Cisneros became viceroy in the name of Ferdinand. In compliance with the urgent appeals of the people, he opened the trade of the country to foreign nations; and on the 25th May 1810, a council was formed, with his consent, under the title of the Provisional Government of the provinces of the Rio de la Plata. This has since been regarded as the commencement of the era of the political independence of the country. Of this council Mariano Morino, the secretary, was the most prominent member, and the people of the city of Buenos Ayres were for some time its only effective supporters An attempt of the Spanish party to make Cisneros president of the council failed, and he retired to Monte Video. On the 31st January 1813 a congress was assembled at Buenos Ayres, and Posadas was elected dictator of the republic. Monte Video still supported the cause of Spain, but was besieged by the revolutionary army of Buenos Ayres, and capitulated in 1814. A sanguinary struggle between the party of independence and the adherents of Spain spread over all the country of the River Plate; but on the 25th March 1816, a new congress of deputies elected by the people was assembled at Tucuman, where Payridon was declared president of the republic; and on the 9th July the separation of the country from Spain was formally declared, and a state of comparative order was re-established. Buenos Ayres was then declared the seat of government. The whole of the viceroyalty did not, however, acknowledge this Government. Bolivia, Paraguay, and Uruguay, established themselves each as a separate republic, after passing through scenes of disorder, whilst the city of Buenos Ayres was itself the scene of sanguinary disturbances. From this time, however, the struggle for independence became, as regards the Argentine Republic, more of a foreign than a domestic war. The combined forces of Buenos Ayres and Chili defeated the Spaniards at Chacabuco in 1817, and at Maypu in 1818; and from Chili the victorious General San Martin led his troops into Peru, where, on the 9th July 1821, he made a triumphal entry into the city of Lima, which had been the greatest stronghold of the Spanish power, having been, from the time of its foundation by Pizarro, the seat of government of the viceroyalty of Peru. A general congress was assembled at Buenos Ayres on the 1st March 1822, in the presence of ambassadors from all the liberated states, and a general amnesty was decreed, though the war was not ended until the 9th December 1824, when the republican forces gained the final victory of Ayacucho, in the Peruvian districts of the Amazon. The Spanish Government did not, however, formally acknowledge the independence of the country until the year 1842. On the 23d January 1825, a National Constitution for the federal states which form the present Argentine Republic was decreed; and on the 2d February of the same year, Sir Woodbine Parish, acting under the instructions of Mr Canning, signed a commercial treaty in Buenos Ayres, by which the British Government acknowledged the independence of the country. For details of the history of the country up to the time of independence the reader is referred to the work of Sir Woodbine Parish, and to the *Historia Argentina*, published in Buenos Ayres. These works have been followed in this short narrative, except when otherwise stated, or in unquestionable matters to which they do not allude.

Whilst the events already described were in progress, Buenos Ayres was involved in a war with Brazil, in consequence of the Government of the country having, in 1817, taken possession of the Banda Oriental, which, under the rule of Artigas, had become a scene of anarchy. Buenos Ayres, unassisted by the northern provinces, waged war with Brazil for the possession of the Banda Oriental, until, in the year 1827, by the mediation of England, that country was made independent of both powers. The origin and progress of that war are more connected with the history of the Oriental than with that of the Argentine Republic. Under the new régime, inaugurated as above described in 1825, Rivadavia, who was elected president, endeavoured to establish a strong central government; and his party obtained the name of Unitarians in contradistinction to their opponents the Federals, who endeavoured to keep each state or province as independent as possible of the National Government. At the expiration of Rivadavia's term of office his opponents triumphed in the election of Vicente Lopez as president; and he was followed in 1827 by Dorrego, another representative of the Federal party. The Unitarians, under the leadership of General Lavalle and his troops, relieved from the war in the Banda Oriental, rebelled against the administration, and in 1828 they defeated the Federals, under Dorrego and General Rosas, in a battle in which Dorrego was taken prisoner and afterwards shot. General Rosas then became chief of the Federal party. In 1829 he defeated Lavalle; and obtaining from Congress, during a "reign of terror," such extraordinary powers as enabled him to rule as dictator, he became as hostile to many members of the Federal party as to the Unitarians. In 1838, a dispute between Rosas and the French Government led to a blockade of the port of Buenos Ayres by the French fleet; and, encouraged by this occurrence, Lavalle, in 1839, returned to the country to rally the Unitarian party. In 1840 he invaded the province of Buenos Ayres at the head of troops raised chiefly in the province of Entre Rios; but he was routed by the Federal army under General Pacheco, and was chased as far as the city of Jujuy, where he was overtaken and shot by troops under the command of Oribe. The rule of Rosas was now one of terror and almost incessant bloodshed in Buenos Ayres, whilst his partisans, General Oribe and Colonel Mazza, endeavoured to exterminate the Unitarians throughout the province. This scene of slaughter was extended to the Banda Oriental by the attempt of Oribe, with the support of Rosas, and of Urquiza, governor of Entre Rios, to establish himself as president of that republic, whose existing Government was hostile to Rosas, and sheltered all political refugees from the country under his despotic rule. The siege of Monte Video by the forces of Rosas led to a joint intervention of England and France, and in 1845 the English minister plenipotentiary declared Buenos Ayres blockaded, and determined to establish direct communications with the Republic of Paraguay by ascending the Parana, the right of navigating which was denied to foreign flags by Rosas, who had always refused to acknowledge the separation of the Government of Paraguay from the authority of Buenos Ayres. At Point Obligado, just above the delta of the river, a severe fight occurred, in which the men of the combined squadrons landed and carried the batteries by storm, after Captain Hope of the "Firebrand" and his crew had succeeded in cutting a heavy iron chain which closed the river under their fire. The allied forces then proceeded to Paraguay, and proclaimed the navigation of the mighty river which forms the highway to that country free to all nations. Ineffectual attempts were made by the allies to induce the people of the River Plate, and more especially Urquiza, to rise against the despotic rule of Rosas; and finding the accomplishment of this impracticable without an army, they withdrew their several forces, and raised the blockade of Buenos Ayres in 1847. Brazil, whose alliance England and France had rejected in consequence of the opposition of that country to the English policy in the suppression of the slave trade, now came to terms with Urquiza; and the forces of Brazil, under Caxias, allied with those raised and commanded by Urquiza, invaded the province of Buenos Ayres, and routed the army of Rosas on the 3d February 1852 at Monte Caseros, about 10 miles from the city. Rosas escaped from the battlefield in disguise, and sought protection at the house of the English *chargé d'affaires*, by whom he was conveyed on board H.B.M. steamer "Locust," leaving the city in a delirium of joy at its sudden emancipation from his tyranny. A provisional Government was formed under Urquiza, and the Brazilian and Oriental troops retired. Urquiza then assembled all the provincial governors at San Nicholas, in the province of Buenos Ayres, and on the 31st May they proclaimed a new constitution, with Urquiza as provisional director of the Argentine nation. This constitution gave each province two representatives in the Senate or Upper Chamber of a Congress of Representatives, which was duly elected and met at Santa Fé; but the people of Buenos Ayres, considering that their political and commercial pre-eminence were not duly represented in the Congress, rose in rebellion against it on the 11th September. Alsina then became governor of Buenos Ayres; and in the new civil war which was now inaugurated might be regarded as the representative of the city, which was his chief support, in opposition to the peasantry, who throughout the country districts were chiefly partisans of Urquiza, or of Rosas. Alsina resigned office in face of a rising of the country districts, under Colonel Lagos, in favour of a restoration of Rosas; but Pacheco, who had defeated the Unitarian General Lavalle in 1840, rallied the city party, and with the support of the most influential citizens, proclaimed the aged General Pintos provisional governor, and the influence of the leading members of the foreign community was actively exerted in his favour. The defence of the city, now besieged by Lagos, was entrusted to General Hornos; and Urquiza, having been duly elected president by the other thirteen provinces, came to terms with Lagos, and took command of the army of the besiegers; and in April 1853 his fleet blockaded the port. In July the besiegers suddenly disappeared without awaiting an expected sally of the city forces under General Paz, now commander-in-chief. Urquiza signed, on board H.B.M. steamer "Locust," as representative of the thirteen provinces, a treaty with Sir Charles Hotham, by which the free navigation of the rivers was confirmed. The province of Buenos Ayres then became established as an independent state, and inaugurated an era of commercial and political development, with Obligado as constitutional governor, whilst Parana became the capital of the thirteen provinces under Urquiza. Differential duties imposed by the Confederation for the purpose of preventing the foreign trade of the confederated states from taking its ordinary course through Buenos Ayres caused great irritation in the latter province; but peace was, nevertheless, maintained until 1859, when Alsina again became governor of Buenos Ayres, and the numerous questions in dispute soon led to active hostilities between the Government at Parana and Buenos Ayres. The army of the latter, under General (then Colonel) Mitre, was defeated by the Confederate forces at Cepeda, in the province of Buenos Ayres, in October 1859; and Urquiza re-entered the city, when Alsina resigned his office of governor to Ocampo, and Buenos Ayres rejoined the Confederation, of which Urquiza resigned the presidency. Derqui was then elected president of the fourteen provinces, with the seat of government at Parana; whilst Urquiza became governor of Entre Rios, and Mitre governor of Buenos Ayres. Hostilities, however, recommenced in 1861, and the armies of the opposite parties, under Generals Urquiza and Mitre respectively, met at Pavon, in the province of Santa Fé. Mitre this time was victorious, and in 1862 he was elected president of the Argentine Confederation, of which, with the consent of the provincial Legislature, the city of Buenos Ayres became provisionally the capital. Urquiza retired to the province of Entre Rios, of which he continued to be governor. The history of these struggles is ably told by Mr Latham from a Buenos Ayrean point of view; and also, from the opposite side, by M. De Moussy, in his able and elaborate work dedicated to Urquiza.

In 1864 the Republic of Paraguay commenced war against Brazil, and on the 5th February 1865, President Lopez sent a despatch to the Argentine Government, requesting permission for the passage of a Paraguayan army through the province of Corrientes. This Mitre refused, the neutrality of the country having previously been declared. On the morning of the 13th April a Paraguayan fleet entered the port of Corrientes, and, without any previous warning of belligerent intentions, fired into and took possession of two vessels of the Argentine navy which were lying at anchor in the port, and also fired on the crew as they endeavoured to swim ashore to escape the unexpected slaughter. In the course of the following day a detachment of Paraguayan troops took possession of the city, whilst the main body of an invading army marched across the province, and, crossing the Uruguay, invaded Brazil. The sudden seizure of the vessels in the port of Corrientes was the first notification of war which reached the Argentine Government. The official declaration of war, which was dated the 29th March, and was based on a declaration passed in Congress on the 18th, did not reach the Argentine Government until the 3d May. The people of Buenos Ayres were thrown into a frenzy of indignation on the receipt of the news of the above-mentioned hostilities; and on the 1st May a treaty was signed between the Argentine Government, Brazil, and the Oriental Republic, by which these powers mutually bound themselves not to lay down their arms until they had abolished the Government of Lopez, but at the same time guaranteeing the independence of Paraguay. Thus the National Government established at Buenos Ayres was launched into a war which sorely tried its resources, both for the prosecution of the war itself, and for the suppression of the opponents of its policy in some districts. The war was soon carried into Paraguay; but the withdrawal of the main body of the Argentine army, under Generals Paunero and Arredondo, was necessitated by a rebellion in the north-west (January 1867), where the rebels, under Saa and Videla, had obtained control of several of the Provincial Governments. The rebel army was not able to cope with the veterans fresh from the battlefields of Paraguay, who drove them across the Andes into Chili, where they laid down their arms. These internal troubles made it requisite for Mitre to retire from the post of commander-in-chief of the allied forces in the field, which then devolved upon the Brazilian General Caxias. Urquiza, though nominally under the order of the National Government, having, on the outbreak of the war accepted from them the appointment of commander-in-chief of the forces of Entre Rios, virtually held that province in a state of neutrality throughout the war, which was ended by the shooting of Lopez on the 1st March 1870, after the extermination of his army and a large majority of the inhabitants of the country. Urquiza, at the outbreak of the war, was the most renowned and powerful chieftain in the country, and doubt regarding the course he might take was a source of anxiety in Buenos Ayres. He had accumulated immense estates and wealth in Entre Rios; and he was doubtless actuated by an earnest desire to preserve to his province the blessings of peace and commercial prosperity in the midst of the surrounding disturbances. The hope of obtaining support from him is, however, supposed to have encouraged the rebellion of the north-western provinces, which neutralised the reckless audacity with which the Argentine troops fought their first battle in Paraguay. In 1868, whilst the war was going on, Mitre's term of office as president expired, and Sarmiento was peacefully elected in his place. The close of the Paraguayan war did not bring permanent peace to the country; for, on the 12th April 1870, Urquiza was assassinated at his family residence by some well-known officers of his army, and the provincial Legislature immediately elected Lopez Jordan as governor in his place. The new governor, in his address to Congress on his installation, took upon himself the responsibility of the assassination, and the National Government refused to acknowledge him as governor of the province, on the ground of undue influence having been brought to bear on the members of the Legislature by which he had been elected. The National troops accordingly invaded the province, for the avowed purpose of affording protection for the free expression of opinion in a new election. This became the commencement of a civil war, which materially interfered with the former prosperity of the province, but which was fortunately brought to a conclusion in the end of January 1873, by the Entre-Riano army being completely routed by the National troops, armed with Remington rifles, under Colonel Gainza. The Entre-Riano leader, with about 40 followers, escaped across the Uruguay. Tranquillity has since that time prevailed in Entre Rios.

Whilst these events were in progress, a rupture between the Argentine Republic and Brazil regarding the settlement of the boundaries of Paraguay, was at one time imminent; but, by the influence of Mitre, who went as special envoy to Rio on the occasion, the friendly relations of the two Governments have, it is hoped, been placed on a secure basis.

The prosperity of the country received a temporary check in 1874, from a brief revolution initiated when President Avellanda was declared elected. The unsuccessful party, under Brigadier-General Mitre, incensed at their defeat, asserted that the elections had been gained by corrupt and fraudulent practices, and resolved to appeal to arms to overthrew the president-elect. The revolution was declared on 24th September. President Sarmiento, whose tenure of office was just expiring, took active measures to repress the revolt; and no collision of forces had taken place when the new president, Don Nicolas Avellanda, was constitutionally installed on the 12th October. The president followed up with energy the measures of his predecessor to suppress the revolution, and his efforts were crowned with success in two decisive victories over the insurgents by the Government troops;

whereupon Generals Mitre and Arredondo, with their forces, surrendered at discretion, and were made prisoners (Dec. 2). The revolution had lasted but seventy-six days. On the 17th December a state holiday was declared, and dedicated to rejoicings on the restoration of peace. The complete and absolute crushing of this revolution has great significance, as it has brought about the dissolution of a powerful and ambitious party, whose movements might have seriously affected the onward march of the country. Those who know the country believe that it will be long before any similar revolutionary attempts can be made with the slightest hopes of success, or the welfare of one of the most favoured countries in the world jeopardised by internal commotion.

Political divisions and population.

The following table gives the names of the fourteen provinces which form the Argentine Republic, together with the superficial area of the country as given by the Statistical Department of the National Government, and the population according to the census of the year 1869, the numbers given as the population of the Indian territory being the official estimate of that year. As regards the area, it must be observed that, according to the *Almanach de Gotha*, an estimate by the Geographical Institute of G. Perthes at Gotha, reduces that given in this table by about one-fourth:—

	Area in square miles.	Population in 1869.
The Riverine Provinces—		
Buenos Ayres	80,400	495,000
Santa Fé	43,700	89,000
Entre Rios	43,100	134,000
Corrientes	47,700	129,000
The Upper Provinces—		
Cordova	83,500	211,000
Santiago	42,000	133,000
Tucuman	59,900	109,000
Salta	24,000	89,000
Jujuy	36,000	40,000
Catamarca	92,900	80,000
La Rioja	42,000	50,000
The Provinces of Cayo—		
San Luiz	48,500	53,000
Mendoza	59,900	65,000
San Juan	39,600	60,000
	743,200	1,737,000
Indian Territories—		
The Chaco	240,000	45,000
The Central and Western Pampas, and Patagonia	636,300	48,000
	1,619,500	1,830,000

The Indian territories and the frontier districts.

The most remarkable features of the present state of the country, as shown by the foregoing table, are the vast extent of the Indian territory and the small number of its inhabitants. Excepting a comparatively narrow tract of land stretching from the southern part of the province of Santa Fé into that of Cordova, and dividing the Indians of the Chaco from those of the Pampas, the dominions of the Indians may be said to extend from the extreme south of the republic, over all the plains of Patagonia, the central parts of the Pampas, and through the Chaco, into the territories of Paraguay and Bolivia. The civilised districts of the west and north-west, which we have seen were settled, the former by way of Chili, and the latter by way of Peru, have now established means of communication with those of the east, except through the district just mentioned. In that district civilisation, of which the Central Argentine Railway is the chief representative, is rapidly establishing and extending itself; but even during the last few years warfare with the Indians on both sides of the line of railway has been almost incessant. In the neighbourhood of Frayle Muerto or Belleville, many Englishmen possessed of some amount of capital established themselves some years ago as cattle farmers, under the protection of modern rifles; but they have been obliged to turn their attention to sheep and agriculture, as offering less tempting plunder to the Indians. It is interesting to record that the city of Cordova, on the west of the Chaco, was founded on the same day, in 1573, as the city of Santa Fé, on the east of that region; and an exploring party from the latter city was saved from being exterminated by the Indians by the timely and unexpected assistance of another party of explorers from the city of Cordova. To the north of Belleville, the land lying between the cities just mentioned is now being peopled by families of Swiss, German, French, Italian, English, and Anglo-American immigrants, who are encouraged by liberal grants of land and assistance from the Provincial Government of Santa Fé; and they appear to be gradually establishing themselves in the country, notwithstanding the hardships they have suffered from the ravages of locusts and the hostility of the Indians. Some of the tribes of the Chaco are among the most savage and intractable in the territory of the republic, though even before the arrival of the Spaniards they supported themselves to some extent by agriculture, and were not so nomadic as the hunting tribes of the south. On the Pampas the Indians appear to be in larger tribes, and their warfare is more formal, since powerful chiefs of the different tribes have considerable control over them, and they in general conform themselves to the policy of peace or war determined on by their chiefs. For many years past the border lands between the Indians and the European settlers in the province of Buenos Ayres have been a scene of constant bloodshed; and some of the Indian invasions have been made on a very extensive scale by a combination of the different tribes. The relations of the Argentine Government with the Indians, it will thus be seen, are in a very unsatisfactory state; and in the midst of all this the condition of the Argentine peasant, or Gaucho, is most deplorable. He has constantly been subject to conscription for service in the army engaged in foreign or civil wars, leaving in the frontier districts his home defenceless against the depredations of the savages. It is true that the Gauchoes may be said to be the primary cause of the civil wars which have devastated the country; for, despising, or at least not appreciating, their constitutional influence, they have been accustomed to regard war as a normal means of subsistence, and to be used as such for its own sake. Nevertheless, in face of the peculiar hardship of the condition of these men, even though in the aggregate self-inflicted, it is scarcely surprising that immigrants are occasionally subjected to annoyances and dangers through a spirit of hostility engendered by feelings of envy, as the Gaucho is subjected to the conscription, whilst the foreigner is undisturbed in his industrious occupations. Families have fallen victims to the sudden outburst of animosity on the part of the Gauchoes, who when once roused have been as cruel as the Indians; and, though the arguments which might be pleaded in extenuation for the latter cannot be applied to the former, their condition is a practical evil, and enlightened legislation for these frontier districts is one of the most urgent necessities of the country. The war with Paraguay, and subsequently the war in Entre Rios, have exhausted the resources of the Government, leaving the Indian frontier almost undefended. The tribes of the Pampas have established settlements, from which they scour the country in pursuit of game; and it is not improbable that some of their recent raids upon the civilised districts have been forced upon them by the immediate necessities of their position, resulting from their improvident mode of living and the absence of agricultural pursuits among them. On the slopes of the Sierra Ventana, north of Bahia Blanca, many Englishmen have established themselves as sheep farmers, where the land stretches away into the Indian territories, without an armed force or a barrier of any sort intervening, and their protection from the savages lies in the respect the latter have for the Snider rifle, combined with the greater attraction which the cattle farms of the north have for the plunderers. On the Rio Negro English settlers are engaged in agricultural pursuits on a soil whose fertility for the production of wheat and other cereals may be said to be unrivalled. To the south of this the country to a great extent accords with the description erroneously applied to all the country south of the River Plate by Guerara, who says that it is a barren land without timber for building, without firewood, without water, without soil to receive seed, and without anything that a city requires for its maintenance. Nevertheless, in the country thus described, a Welsh colony has established itself on the Chupat River; and, though at first they suffered severe hardships, and were saved from starvation only by food supplied by the Tehuelche Indians in the first instance, and afterwards by similar supplies from the Argentine Government, there appears no reason now why it should not become a prosperous colony. In the far south, on the Santa Cruz River, the Argentine Government have a military establishment. The tribes of Patagonia do not appear to have any settled villages, but make the whole country a vast hunting ground. The different parties meet in their excursions either as friends or as foes, just as accident, the humour of the moment, or any occasion of enmity between the chieftains determines. The game on which they live is superabundant, and the chief impediment to an increase of the population seems to be the remorseless butchery which ensues on the meeting of hostile hunting tribes, which sometimes results in the extermination of one party or the other; and also the incessant slaughter resulting from sudden quarrels among members of the same party. Lieutenant Musters, of the Royal Navy, has recently traversed the country from the Strait of Magellan to the Rio Negro with one of the hunting tribes; his book may be commended to those who desire to be better acquainted with that wild country and its inhabitants. The Tehuelche Indians, with whom he travelled, average about 5 feet 10 inches in stature, but he describes the Araucanians as somewhat taller and equally athletic. All the Indian tribes have more or less of the peculiar characteristics of the red or copper-coloured race, and analogies in the languages of the numerous tribes also indicate an identity of origin. According to their traditions at the time of the discovery of the country by the Spaniards, as recorded by Guerara, their ancestors came from the north, and they also held confused traditions of the disasters of the deluge.

Government. The foregoing historical sketch will have given the reader some insight into the government of the country. The framers of the Constitution professed to be guided by that of the United States of North America, and freely adopted the liberal principles there embodied. The president is elected for a term of six years, and the president of the Senate, elected to that office by his fellow-senators, becomes ex-officio vice-president of the republic. The government is conducted by a ministry responsible to Congress, and an adverse vote of the Senate and deputies on any important question leads to the formation of a new ministry. The number of senators and deputies returned by each province is in proportion to the number of its inhabitants. Each province has its own independent form of government for all matters not expressly delegated to the National Government, and is supposed to have irresponsible jurisdiction in its own affairs so long as the articles of the National Constitution are not contravened. The city of Buenos Ayres, besides being the seat of the Government of the province, is also the seat of the National Government, having been so declared by the Constitution, until such time as a suitable site for a new capital for the republic may be determined on by the Legislature. Not only the Constitution itself, but also the spirit in which its enactments are carried out, is thoroughly liberal, and worthy of the magnificent country over which civilisation, under its enlightened regulation, is struggling successfully against barbarism. Fresh arrivals from Europe are not only cordially welcomed, but every effort is made by the authorities to induce foreigners to settle in the country. They are free either to naturalise themselves as Argentines, or to maintain their foreign nationality; in the latter case they have not the privilege of a vote in the government of the country, nor are they liable to the conscription for service in the army. In other respects the law is the same for all. Every one born in the country is by law an Argentine.

Inhabitants. The population of the city of Buenos Ayres is almost thoroughly European, nearly one-half being, in fact, foreigners born in Europe. But on passing from that city into the country the Mestizo race becomes more prominent; and in the northern provinces, as in Paraguay and Peru, the Mestizoes, with Indian blood predominating, form the majority of the population. The Negroes, or Mestizoes in whom Negro blood can be traced, do not form an important part of the population as they do in Brazil. The difference between the two countries in this respect is, in fact, very striking. Slavery was abolished during the war of independence; and the importation of Negroes, which had never been an extensive trade, then ceased; and the constant stream of immigration from Europe, which of late years has been steadily augmenting, is gradually changing the aspect of the population of the country. In 1858 the arrivals amounted to only 4600 persons; but they increased every year till they amounted to 29,000 in 1868, 37,000 in 1869, 41,000 in 1870, 20,000 in 1871, 40,000 in 1872, 80,000 in 1873, and about 90,000 in 1874. This constantly increasing stream of immigration has been absorbed into the various industries of the country as fast as the new arrivals reach its shores. As regards the nationalities of the immigrants, the Italians are the most numerous, then the French, Spaniards, Germans, English, and Swiss. During the above-mentioned years the new arrivals have almost always found their services eagerly sought for at wages of 8 to 10 shillings a day for the most ordinary employments, and at proportionally higher rates for skilled workmen. The comparatively small amount of the immigration in 1871 is due to the occurrence of the epidemic of yellow fever which decimated the population of the city of Buenos Ayres in the early part of that year, and caused the bulk of the emigrants from Europe on their way to the country to stop at the ports of Brazil and at Monte Video, and turned the tide of emigration from Europe in other directions at the close of the year. Though this terrible pestilence is said to have been imported from Brazil, its rapid spread in the city can clearly be ascribed to temporary causes which even the unrivalled salubrity of the climate was insufficient to neutralise. In the absence of any artificial drainage the cleanliness of the city had depended on its occasional scouring by the heavy rains, whilst an ever increasing number of cesspools have been accumulating filth beneath the houses; and up to the year 1870 the consumption of water, beyond the amount of rain-water accumulated in tanks in the houses of the wealthy, was limited by the cost of cartage from the river; but in that year new water-works were opened, by which a supply is pumped up from the river, and conveyed by pipes to all parts of the city, and the increased waste of water may, by leading to an unusual disturbance of the cesspools, have partly contributed to the spread of the epidemic. Though frightfully contagious in the city, the disease was not so in the country; and no instance could, it is believed, be recorded in which it was communicated to those who nursed patients that took the disease from the city, and sickened and died in the suburbs. It is hoped that the extensive drainage works which the Provincial Government is having constructed under the superintendence of Mr Bateman will obviate the risk of another outbreak of a plague, which whilst it lasted put a stop to commercial pursuits and almost disorganised society. The total number of foreigners in the Argentine Republic at the time of the last census, was, according to the *Almanach de Gotha*, 212,000. A recent writer, who has given particular attention to the subject, says, "There are about 40,000, between Irish, Scotch, and English settlers and their families, in quiet and undisputed possession of about two millions of acres of land in the province of Buenos Ayres alone; in the full enjoyment of all religious and social liberty. They own upwards of 35,000,000 sheep, besides horned cattle, horses, and valuable buildings . . . . The bulk of this vast property has been acquired in the country by men who on their arrival did not possess a sixpence."

Industries and foreign trade.

Excepting the mining districts in the north-west of the republic, the agricultural district of Chivilcoy, in the north of the province of Buenos Ayres, the agricultural colonies of Santa Fé, and the establishments of the English settlers in the north of Patagonia, the Argentine Republic is at present a pastoral country. The manufacturing and agricultural pursuits of the north-western provinces are not important items in the general wealth of the republic. The development of its vast resources as a mining and agricultural country has scarcely commenced; and its greatest wealth is at present represented by the herds of cattle and sheep which graze upon its fertile plains. The manufactures and luxuries imported into the country are paid for with the annual increase of these flocks and herds, though the latter are not so numerous as in an equal area of Central and Western Europe. The number of herd cattle in the country may be roughly estimated at from 15 to 18 millions; of which, in the year 1866, the province of Buenos Ayres contained 6,800,000; Entre Rios, 2,500,000; and Corrientes, 2,000,000. In the same year Buenos Ayres contained 60,000,000 sheep; and Entre Rios and Corrientes together, 7,000,000. The number of sheep in the whole country is estimated at 100,000,000.

The extent of the trade which the Argentine Republic carries on with different foreign countries is indicated in the subjoined tabular statement of values of the imports and exports of the whole country, for 1873. The amounts are given in hard dollars, of which the sterling equivalent is about 49 pence.

Argentine Trade Report for 1873.

	Imports.	Exports.
Great Britain	$19,344,143	$9,894,007
France	18,255,138	8,677,819
Belgium	2,967,586	13,891,508
United States	5,167,616	3,032,945
Italy	3,784,384	1,487,925
Spain	2,952,600	1,231,697
Chili	1,444,182	2,365,475
Brazil	2,968,953	769,464
Uruguay	2,735,293	992,949
Germany	3,228,015	449,597
Holland	1,611,616	226,204
Other countries	1,999,341	2,100,515
Hard dollars	$66,458,873	$45,122,105
Or about	£13,568,000	£9,200,000

The principal items of the import trade from Great Britain are as follows (the figures representing hard dollars as before):—Cotton goods, 2,359,000; woollen, 904,000; other textures, 3,364,000; clothing, 1,367,000, besides 951,000 in shoes; iron, 2,757,000; and railway materials, 1,706,000. France sends wines to the value of 4½ millions; textile fabrics, 2½; clothing, shoes, &c., 2½; hardware, fancy goods, &c., 6½. More than half the value of the United States imports (2,769,000) is in lumber. The whole import trade of the country in 1873 exceeded that of 1870 by 49 per cent.

The following table exhibits the amount, values, and principal destinations of the more important articles of export for 1873:—

Wool	185,000,000 lb	$19,600,000	whereof $10,000,000 to Belgium.
Tallow	85,000,000 lb	5,500,000	" 2,652,000 to England.
Sheepskins	55,000,000 lb	4,000,000	" 1,854,000 to England.
Dry Hides	1,700,000	5,140,000	" 1,353,000 to United States
Salted, do	1,300,000	4,500,000	" 2,720,000 to England.
Jerked Beef	88,000,000 lb	1,400,000	mostly to Brazil and West Indies.
Cattle	180,000	2,700,000	to other South American countries.

Other items of export are metals (copper and silver) of the value of 420,000 dollars; grain, 120,000; ostrich feathers, 150,000. The entire export trade of 1873 shows an increase of 55 per cent. on the trade of 1870.

The tonnage of the vessels that arrived and cleared during the four years 1870 to 1873 was as follows:—

	Steamers.	Sailing Vessels.	Gross Tonnage.
1870	808,000	712,000	1,520,000
1871	863,000	662,000	1,525,000
1872	1,190,000	960,000	2,150,000
1873	1,135,000	753,000	1,888,000

Of this tonnage the proportion returned for English vessels is no less than 30 per cent.; French vessels rank next, with 16 per cent.; then Argentine and Italian, 12 per cent. each. There are twelve lines of steamers constantly plying between Europe and Buenos Ayres. The passage occupies about twenty-nine days.

The advancement of the Argentine Republic has received a great impetus from the introduction of steam communication and telegraphy. The first railway was opened in 1857; and in 1874 there were more than 800 miles open for traffic, with about 1000 miles more in course of construction. A system of tramways was commenced in the city of Buenos Ayres in 1869. There are now about 80 miles within the city and suburbs, and this means of transit is being extended to all the smaller towns. There are in use within the republic above 7000 miles of telegraphic wires. Complete communication is now established with Europe, the first telegrams having been exchanged with London on 4th August 1874.

The province of Buenos Ayres is, in wealth and general importance, far in advance of all the other provinces of the Confederation. Under the enlightened administration of Señor Castro, the late governor, great improvements have been made in the means of communication throughout the province, which is the first step requisite for the due development of its resources. Besides railway extensions a great number of iron bridges have been imported from England and erected under the superintendence of Mr Coghlan, by order of the Provincial Government of Buenos Ayres. The National and Provincial Governments established in the city of Buenos Ayres are rivals in their efforts to promote the true welfare and prosperity of the country. Señor Acosta, the governor of the province, may be relied on to continue the policy of assisting the development of the resources of the country, which may almost be said to have been inaugurated by his predecessor. And his Excellency Señor Sarmiento, whose term of office as president of the republic expired in October 1874, must, from his unceasing exertions in the cause of education, be regarded as one of the greatest benefactors of the country.

The following are the returns of the national revenue

Finance.

collected in the years 1866 and 1872 respectively, the figures representing hard dollars as before:—

	1866.	1872.
Import Duties ...	6,686,000	14,464,827
Export ...	2,164,000	2,621,353
Warehousing	263,000	504,212
Stamp Duties	127,000	310,806
Post Office ...	57,000	137,434
Property Tax	196,000	62,226
Sundries ...	68,000	71,512
	9,561,000	18,172,379

The revenue, as shown by the above tables, is obtained chiefly from the Custom-House; and of the duties on the foreign trade of the country more than four-fifths are collected in Buenos Ayres. The ordinary expenditure for 1872 is returned as 7,419,832 dollars; but to this the interest of the national debt has to be added, with other extraordinary expenditure, raising the whole amount to 23,992,975 dollars. The deficit in 1872 was thus 5,820,596 dollars. Besides the expenses of the National Government, each province has its separate revenue. That of the province of Buenos Ayres amounted in 1871, as shown by the Report of the provincial minister of finance, to more than 5.000,000 hard dollars. The following statement of the national debt of the republic at the end of 1872, is taken from the *Almanach de Gotha* for 1875:—

		Hard Dollars.
English Loan of 1824, 6 and 3 per cent.	£1,770,100	8,672,590
Foreign Loans		1,757,645
English Loan of 1868	£2,209,100	10,824,590
English Loan of 1871, 6 per cent. interest, and 2½ per cent. amortisation	£5,885,900	28,840,910
Total amount of Foreign debt		50,095,735
Home debt, 6 per cent., and 1 per cent. amortisation		18,055,623
Home debt, 6 per cent., and 2½ per cent. amortisation		1,802,353
Roads and Bridges, 8 per cent. interest		1,033,000
Total of National debt		70,986,711
Buenos Ayres Provincial Debt:—		
6 per cent. interest, and 3 per cent. amortisation		636,000
9 per cent. interest, and 3 per cent. amortisation		910,000
Total (about £14,800,000 sterling)		72,532,711

Further information respecting the republic will be found under BUENOS AYRES and other headings. (W. L. J.)

ARGOL, the commercial name under which the crude tartar of commerce is known. It is a semi-crystalline deposit which forms on wine vats, and is either grey or red according to the colour of the wine from which it separates.

ARGONAUTS, in *Greek Legend*, a band of heroes who sailed in the ship "Argo" from Iolcus, in Thessaly, to Æa, in Colchis, on the further shore of the Black Sea, to fetch the golden fleece, which was there guarded by a dragon in a grove sacred to Mars. This task had been imposed on Jason that he might prove himself by a perilous adventure worthy of the throne of Iolcus, which he claimed from the usurper Pelias, at whose hands he and his father Æson had suffered persecution. To accompany him, Jason, when the "Argo" was ready, called upon the principal heroes of his own race, the Minyæ, whose distant voyages and colonisation in very early times seem to have suggested the legend of this expedition. Of these Acastus the son of Pelias, Admetus of Pheræ, Euphemus (represented as connected with the colonisation of Thera and Cyrene), Periclymenus, Erginus, and Tiphys the steersman, joined him. So far the crew appears well fitted to conduct the "Argo" to Colchis, leaving Jason to reserve his strength for the culminating act, in which also they had mostly, apart from their friendship for Jason, a special interest, because of previous events connected with the golden fleece, the story of which was as follows. Jason's uncle Athamas had by his wife Nephele two children, Phrixus and Helle. The mother died, and her place was taken by Ino, a daughter of Cadmus, who from hatred of her step-children persuaded Athamas, by means of a false oracle, to offer his son Phrixus as a sacrifice, in consequence of a famine which she had caused by having the grain secretly roasted before it was sown. But before the sacrifice the shade of Nephele appeared to Phrixus, bringing a ram with a golden fleece, on which he and his sister Helle were to escape over the sea. Helle fell off and was drowned in the strait, which thence took the name of Hellespont. Phrixus reached the other side, and proceeding on land to Colchis, sacrificed the ram, and hung up its fleece in the grove of Mars. With the family of Athamas the original crew of the "Argo" were more or less connected. But in the later versions of the story it is clear that such a voyage could not in after times be conceived without a variety of adventures, for which other and better known heroes had to be added. Of these the chief were Hercules, Castor and Pollux, Orpheus, Mopsus, and the sons of Boreas, Calaïs and Zetes. The outward course of the "Argo" was the same as that of the Greek traders, whose settlements as early as the 6th century B.C. dotted the southern shore of the Black Sea. The first landing-place was Lemnus, which the Argonauts found occupied only by women who, at the instigation of Aphrodite, had slain their husbands, fathers, &c. Here some stay was made, and Hypsipyle bore Jason a son, Euneos, who afterwards traded with the Greeks before Troy and with the Phœnicians. That the Minyæ had at a very early period formed settlements in Lemnus is known from Herodotus (iv. 145). They landed at Cyzicus next, and here occurred the incident of Hercules and Hylas. The former having broken an oar after they started, went into a wood to cut a new one, Hylas accompanying him to fetch water. Some nymphs admiring the beauty of the youth carried him off. Hercules followed his cries, but could not find him. Nor was he ever found, though the hero exacted hostages till this should be done. On reaching the modern Scutari, they again landed to get water, and were challenged by the king, Amycus, to match him with a boxer. Pollux came forward, and in the end overpowered his adversary, and bound him to a tree. At the entrance to the Black Sea they met Phineus, the blind and aged king whose food was being constantly polluted by the Harpies. He knew the course to Colchis, and offered to tell it, if the Argonauts would free him from the Harpies. This was done by the winged sons of Boreas, and Phineus now told them their course, and that the way to pass through the Symplegades—two cliffs which moved on their bases and crushed whatever sought to pass—was first to fly a pigeon through, and when the cliffs, having closed on the pigeon, began to retire to each side, to row the "Argo" swiftly through. His advice was successfully followed. The next place they landed at, and the last before reaching Colchis, was Heraclea, where the steersman Tiphys died. To the early Greeks Colchis was the eastern extremity of the earth, as the Pillars of Hercules were the western. Behind both was the Oceanus, into which the river Phasis flowed at Colchis. At Colchis was the rising of the sun, and Æetes the king was a son of Helios; while his daughter Medea was, by her knowledge of witchcraft, connected with the worship of the moon. Æetes required of Jason that he should first yoke to a plough his bulls which snorted fire and had hoofs of brass, and with them plough the field of Mars. That done, the field was to be sown with dragons' teeth, from which armed men were to spring. Successful so far by means of the mixture which Medea had given him as proof against fire and sword, Jason was next allowed to approach the dragon which watched the fleece; Medea soothed the dragon with another mixture, and Jason became master of the fleece. Then the voyage homeward began, Medea accompanying Jason, and Æetes pursuing them. To delay him and obtain escape, Medea dismembered her young brother Absyrtus, whom she had taken with her, and cast the limbs about in the sea for his father to pick up. In another report Absyrtus had grown to manhood then, and met his death in an encounter with Jason, in pursuit of whom he had been sent. Of the homeward course various accounts are given. In the oldest existing account, the "Argo" sailed along the river Phasis into the Oceanus, thence to the mythical lake Tritonis, after being carried twelve days over land through Libya, and thence again to Iolcus. Hecatæus of Miletus suggested that from the Oceanus it may have sailed into the Nile, and so to the Mediterranean. Others, like Sophocles, described the return voyage as differing from the outward course only in taking the northern instead of the southern shore of the Black Sea. Some supposed that the Argonauts had sailed up the river Tanais, passed into another river, and by it reached the North Sea, returning to the Mediterranean by the Straits of Gibraltar. And again, others laid down the course as up the Danube (Istros), from it into the Adriatic by a supposed mouth of that river, and on to Corcyra, where a storm overtook them. Next they sailed up the Eridanus into the Rhodanus, passing through the country of the Celts and Ligurians, and reaching the Tyrrhenian Sea and the island of Circe, who absolved them from the murder of Absyrtus. Then they passed safely through Scylla and Charybdis, past the Sirens, through the Planctæ, over the island of the Sun, Trinacria, and on to Corcyra again, the land of the Phæacians, where Jason and Medea held their nuptials. They had sighted the coast of the Peloponnesus when a storm overtook them and drove them to the coast of Libya, where they were saved from a quicksand by the local nymphs. The "Argo" was now carried twelve days and twelve nights to the Hesperides, and thence to lake Tritonis, whence Triton conducted them to the Mediterranean. At Crete the brazen Talos, who would not permit them to land, was killed by the Dioscuri. At Anaphe they were saved from a storm by Apollo. Finally they reached Iolcus, and the "Argo" was placed in a grove sacred to Neptune on the isthmus of Corinth. Jason's death, it is said, was afterwards caused by part of the stern giving way and falling upon him. (A. S. M.)

ARGONNE, a rocky and forest-clad plateau in the north-east of France, extending along the borders of Lorraine and Champagne, and forming part of the departments of Ardennes and Meuse. The famous defence of the French frontier by Dumouriez in 1792 is called the Argonne Campaign.

ARGOS. The most important city of this name was situated in the eastern part of the Peloponnesus, about 3 miles from the sea. By the Greeks themselves it was regarded as the most ancient of all their cities, and as the local habitation of many of their earlier heroes. Here Inachus and his descendants had reigned for many generations, until the arrival of Danaus the Egyptian, with his fifty daughters, whose dynasty, glorious with the names of Perseus the Gorgon-slayer, and Eurystheus the master of Hercules, held sway over Argos, and Tiryns, and Mycenæ, till it, in its turn, was succeeded by the still more important dynasty of Pelops. The Dorian invasion and conquest followed, and Argos became the head of a Dorian confederation, extending its authority over a large portion of the neighbouring territory. Between this region (Argolis) and Sparta, however, there were no natural boundaries, and a conflict arose between the two states about the border land of Cynuria. For a time, under the despotic management of Pheidon, Argos maintained its ground; but Sparta ultimately established its claim in spite of the dubious result of the famous duel of the 600, which was fought for the decision of the dispute, and the strength of the Argives was completely crushed by Cleomenes at the battle of Tiryns. A temporary ascendency of the serfs in Argos, an extension of the franchise, and a permanent adoption of a more democratic constitution, seem to have been the consequences of this national exhaustion and the subsequent reaction. During the Persian war Argos was indifferent and neutral, but in the contest for power which ensued between Athens and Sparta, the old antipathy against the latter was sufficient to make the Argives stanch allies of the former. In the 4th century B.C., the democratic constitution of the city degenerated into a reign of terror (Σκυταλισμός), which in its turn gave place to a series of tyrannies, from which escape was ultimately found in the Achæan League and the Roman domination. Pyrrhus perished in an unsuccessful attack on the city in 272 B.C. In the 13th century of our era, Argos fell into the possession of the Franks, from whom it passed into the hands of the Byzantine despots; and in 1463 it was taken by the Ottoman troops. Here in the darkest period of Greek ignorance lived one of the few representatives of the ancient learning, Theodosius Zigomali (Crusius's *Turcogræcia*). In the time of Pausanias the number of temples in Argos and its neighbourhood was remarkable, the most important of them being the Heræum, or temple of Hera, the ruins of which, visible from the acropolis of Argos, but nearer to Mycenæ, were discovered in 1831 by Colonel Gordon of Cairness (see plan in Leake's *Peloponnesiaca*, 1846). Within the city the greatest was the temple of Apollo Lyceus. Remains still exist of the cyclopean architecture of the acropolis, of the theatre, which was of great extent, and of an aqueduct which can be traced for miles to the north-west. In the 5th century B.C., Argos was the seat of a great school of statuary under Ageladas, but it did not contribute to the long roll of Greek literature more than the names of Telesilla and Sacadas, of whom the latter was better known as a musician. The limits of Argolis varied at different times, but it was only under the Romans that they were understood to embrace the districts of Phlius, Cleonæ, Epidaurus, Trœzen, and Cynuria.

ARGOSTOLI, the capital of Cephalonia, one of the Ionian islands, and the seat of a bishop of the Greek Church. It possesses an excellent harbour, a quay a mile in length, and a fine bridge. In 1870 the imports were of the value of 8,347,522 drachmas, or £296,941. Near at hand are the ruins of Cranii, affording fine examples of the military architecture of the Greeks; and at the west side of the harbour there is a curious stream, flowing *from* the sea, which is employed to drive mills. (Sir C. Fellows's *Journal of an Excursion in Asia Minor* in 1838, and Wiebel's *Die Insel Kephalonia und die Meermühlen von Argostoli*, Hamburg, 1873.) Shipbuilding and silk-spinning are carried on. Population, 9000.

ARGOVIE (Lat. *Argovia*), the French form of Aargau, the name of one of the Swiss cantons. See AARGAU.

ARGUIN, an island, perhaps Hanno's *Cerne*, off the west coast of Africa, in lat. 20° 25′ N., long. 16° 37′ W. It produces gum-arabic, and is the seat of a turtle fishery. There are two fairs held every year. Off the island, which was discovered by the Portuguese in 1452, are extensive and very dangerous reefs. There is a town of the same name on the neighbouring coast.

ARGUS, in *Greek Legend*, the son of Agenor or Arestor, or, according to others, an earth-born hero (Autochthon). He was called Panoptes (πανόπτης), All-seeing, from having a hundred eyes. After performing several feats of valour, he was appointed by Juno to watch the cow into which Io had been transformed. While doing this he was slain by Mercury, who, according to one account, stoned him to death, according to another, put him to sleep by playing on the flute, and then cut off his head. His eyes were transferred by Juno to the tail of the peacock.

ARGYLL, Earls and Dukes of. The rise of this family of Scottish peers, originally the Campbells of Lochow, first ennobled as Barons Campbell, and still retaining the family name Campbell, is referred to in the article Argyllshire (*q.v.*)

Archibald, the eighth earl and first marquis, was born in the year 1598, and educated in the principles of the Reformation, of which his ancestors had been zealous promoters. His father, however, renounced Protestantism, whereupon the young earl was put in possession of his patrimonial estates by order of Government, and quickly promoted to places of trust and power. From the commencement of his political career he espoused the cause of the Presbyterian party, and defended the Covenanters when summoned to London to give his opinion of their proceedings before the king. In 1638 he remained with the General Assembly after it had been dissolved by the king's commissioner, and with other nobility and gentry signed the Solemn League and Covenant. Having thus openly committed himself to the Presbyterian cause, he became its recognised leader both in political negotiations and in the field. He was created a marquis during the king's visit to Scotland in 1641. This mark of favour, intended probably to conciliate a powerful subject, did not prevent Argyll from leading an army against the royal troops in 1644. The campaign ended in his signal defeat by Montrose at Inverlochy on the 1st February 1645. In 1651 he placed the crown on the head of King Charles II. at Scone, having, like the rest of his party, been alienated from the republicans of England by the execution of Charles I. Having gone to London at the Restoration in 1660, he was arrested and thrown into prison. In the following year he was tried at Edinburgh for high treason, and, principally on ground of alleged treasonable correspondence with Monk, he was condemned to death, and executed on the 27th of May, dying with great firmness and calmness. He was the author of *Instructions to a Son, and Maxims of State* (1661).

Archibald, the ninth earl, son of the preceding, from his youth distinguished himself by his loyalty and attachment to the royal family. Though his father headed the Covenanters, he attached himself to the king's party. On the establishment of the Commonwealth he was committed to prison, and was jealously watched till the Restoration, when the king remitted his father's forfeiture, and created him earl of Argyll. He continued in high favour with the king and court till the passing of the Test Act in 1681, when, by opposing the exemption of princes of the blood from the oath, he drew down on himself the indignation of the duke of York. When called to take the test, Argyll refused, except with an explanation, which he believed to have been approved by the duke, to the effect that he took it only so far as it was consistent with itself and with the Protestant religion. The duke accepted the qualification, and Argyll was admitted to sit in council; but a few days afterwards he was committed to prison, and indicted for high treason. On being tried, three judges did not scruple to convict him of treason; a jury of fifteen noblemen gave a verdict against him; and the king ordered sentence to be pronounced, but the execution of it suspended till further orders. Argyll, however, seeing no reason to trust to the justice or mercy of his enemies, made his escape from prison, and concealed himself for some time in London, afterwards escaping to Holland, where he remained during the remaining part of the reign of Charles II. On the accession of James II. he took part in the rising of the duke of Monmouth, and returned to Scotland to command the forces raised there; but after a few unsuccessful skirmishes he was taken prisoner and carried to Edinburgh, where he was beheaded on his former sentence, June 30, 1685, submitting to death with heroic firmness.

Archibald, the first duke, son of the preceding, was an active promoter of the Revolution. He came over with the Prince of Orange, and was admitted into the Convention as earl of Argyll, though his father's attainder had not been reversed. Having been deputed, along with Sir James Montgomery and Sir John Dalrymple, to present the crown in name of the Scottish Convention to the Prince of Orange, and to tender to him the coronation oath, he was admitted a member of the Privy Council, and, in 1690, made one of the lords of the Treasury. In 1701 he was created duke of Argyll. He died in 1703.

John, the second duke (also duke of Greenwich), son of the preceding, was born on the 10th October 1678. He entered the army in 1694, and in 1701 was promoted to the command of a regiment. On the death of his father in 1703, he was appointed a member of the Privy Council, and at the same time captain of the Scotch horse guards, and one of the extraordinary lords of Session. In return for his services in promoting the Union, he was created a peer of England, by the titles of baron of Chatham and earl of Greenwich, and in 1710 was made a knight of the Garter. He first distinguished himself in a military capacity at the battle of Oudenarde, where he commanded as brigadier-general; and was afterwards present under the duke of Marlborough at the sieges of Lisle, Ghent, Bruges, and Tournay, and did good service at the battle of Malplaquet in 1709. Soon after this action he was sent to take the command in Spain; but being seized with a violent fever at Barcelona, and disappointed of supplies from home, he returned to England. Having a seat in the House of Lords, he censured the measures of the ministry with such freedom that all his places were disposed of to other noblemen; but at the accession of George I. he recovered his influence. On the breaking out of the Rebellion in 1715 he was appointed commander-in-chief of the forces in North Britain, and was principally instrumental in effecting the total extinction of the rebellion in Scotland without much bloodshed. He arrived in London early in March 1716, and at first stood high in the favour of the king, but in a few months was stripped of his offices. This disgrace, however, did not deter him from the discharge of his parliamentary duties; he supported the bill for the impeachment of Bishop Atterbury, and lent his aid to his countrymen by opposing the bill for punishing the city of Edinburgh for the Porteous riot. In the beginning of the year 1719 he was again admitted into favour, appointed lord-steward of the household, and, in April following, created duke of Greenwich. He continued in the administration during the remaining part of that reign, and, after the accession of George II., till April 1740, when a violent speech against the Government led again to his dismissal from office. He was soon restored, however, on a change of the ministry, but disapproving of the measures of the new administration, he finally resigned all his posts, and spent the rest of his life in privacy and retirement. He died on the 3d September 1743. A monument executed by

Roubillac, has been erected to his memory in Westminster Abbey.

ARCHIBALD, the third duke, brother of the preceding, was born at Ham House in Surrey, in June 1682. On his father being created a duke, he joined the army, and served for a short time under the duke of Marlborough. In 1705 he was appointed treasurer of Scotland, and in the following year was one of the commissioners for treating of the Union; on the consummation of which, having been raised to the peerage of Scotland as earl of Islay, he was chosen one of the sixteen peers for Scotland in the first parliament of Great Britain. In 1711 he was called to the Privy Council, and commanded the royal army at the battle of Sheriffmuir in 1715. He was appointed keeper of the privy seal in 1725, and was afterwards intrusted with the principal management of Scottish affairs. In 1734 he was made keeper of the great seal, an office which he held till his death. He succeeded to the dukedom in 1743. The duke was eminent not only for his political abilities, but for his literary accomplishments, and had collected one of the most valuable private libraries in Great Britain. He died suddenly on the 15th of April 1761.

ARGYLLSHIRE, or ARGYLESHIRE, a county on the west coast of Scotland, comprehending a large district on the mainland and a number of the Hebrides or Western Isles. The mainland portion lies between lat. 55° 15′ and 56° 55′ N., and between long. 4° 32′ and 6° 6′ W.; its greatest length being 115 miles, and its greatest breadth about 36 miles. It is bounded on the N. by Inverness-shire; on the E. by the counties of Perth and Dumbarton, Loch Long, and the Firth of Clyde; on the S. by the North Channel; and on the W. by the Atlantic. Its sea coast has been stated at 600 miles. If the various islands are included, the greatest breadth of the county is 68 miles, and its total area amounts to 3255 square miles, or 2,083,126 acres, which is more than a tenth part of the whole area of Scotland. It contains forty parishes, and has been variously divided at different times into a number of districts. The names of these at present in use are North and South Argyll, Cowal, Dunoon, Kintyre (or Cantyre), Tarbert, Lorn, Mull, Ardnamurchan, Morven, Islay, &c. The principal towns are Inveraray, Dunoon, Campbeltown, Oban, and Tobermory.

There are numerous mountain streams, but no navigable rivers. The two principal are the Orchy and Awe. The former flows from Loch Tulla through Glen Orchy, and falls into Loch Awe at its northern extremity; and the latter forms an outlet for the loch across the neck of land which lies between it and Loch Etive. The other streams are the Add, Aray, Coe or Cona, Creran, Douglas, Echaig, Etive, Euchar, Feochan, Finart, Fyne, Kinglas, Kinloss, Large, Leven, Nell, Ruel, Shiel, Shira, Strae, Talaken, Uisge-Dhu, &c. Most of these yield excellent salmon and trout fishing. There are also some good fishing streams in the islands. The county is remarkable for the numerous inlets of the sea with which it is deeply indented, the principal of them being Loch Long, with its branch Loch Goil; Loch Fyne, with Loch Gilp; Loch Etive; Loch Linnhe, with its branches Loch Creran, Loch Leven, and Loch Eil; and Loch Sunart. There is also a large number of inland lakes, the total area of which is about 25,000 acres. Of these the principal are Loch Awe, Loch Avich, Loch Eck, Loch Lyndoch (partly in Perthshire), and Loch Shiel.

The principal islands are Mull, Islay, Jura, Colonsay, Lismore, Tiree, Coll, Gigha, Muck, Rum, and Canna. Besides these there are the two small but interesting islands of Staffa and Iona—the one famous for its basaltic caves and rocks, and the other as the earliest seat of Christianity in Scotland.

The whole county is rugged and mountainous, and many of the peaks are among the loftiest in the kingdom; as Ben Cruachan (3689 ft.), Ben More, in Mull (3172), Ben Ima (3318), Buchael Etive (3345), and Ben Arthur, "The Cobbler" (2891), on the borders of Dumbartonshire. To the tourist it offers a rich variety of Highland scenery, culminating in the gloomy grandeur of Glencoe.

The situation and conformation of Argyllshire tend to produce a very abundant rainfall. At Oban, the average annual amount is 64·18 inches; in Glen Fyne, 104·11 inches; at the Bridge of Orchy, 113·62 inches; and at Upper Glencoe, 127·65; while at Edinburgh the average quantity is only 26·40 inches. The prevailing winds, as observed at Callton-More, near Crinan, are the S.W. and S.E., and next in frequency are the N.W. and N.E. The average temperature is 48° Fahr.

Geologically, the mainland consists principally of the metamorphic or so-called primary strata, covered in part by newer formations. In the portion west of Lochs Linnhe and Eil—the districts of Sunart, Ardgower, and Morven—gneiss is the prevalent rock, broken through by granite near Strontian, and by trap rocks in Ardnamurchan and Morven. In the other portion east of Loch Linnhe, the lower rocks are chiefly mica slate and clay slate, the continuation of the strata forming the great range of the southern Grampians. Mica slate is the most important and oldest of these formations, rising up into the wild and rugged mountains so conspicuous near Loch Long and Loch Fyne. In Appin it is partly replaced by quartz rock, remarkable for bare sterility, and on Loch Fyne by chlorite slates running down into Knapdale or the upper portion of the promontory of Kintyre. These slates form a good building stone, being readily cut even with a saw, and are the material of which the ducal castle at Inveraray is built. Mica slate again forms most of Kintyre south of Tarbert, with occasional beds of dark coloured limestone.

Clay slate is far less common on the mainland, but occurs near Dunoon and Toward Point on the Clyde. It has been long quarried extensively at Ballachulish, and again appears near Oban and further south, often as a dark coloured carbonaceous-looking rock. From this it extends into Kerrera, Seil, Easdale, Luing, and the other so called slate islands. It has everywhere a very marked cleavage, distinct from the stratification, and some of the beds furnish a very durable roofing slate, which has been long wrought in Easdale, and with which many houses in Scotland are covered. Cubical crystals of iron pyrites abound in all these slates, which, though no organic remains have yet been found in them, are probably the equivalents of the lowest Silurian formations.

To the same period may also be referred the quartz rock mentioned as occurring in Appin, specially near the lower part of Glencoe, and more extensively in Jura and Islay, along with the clay slate. From its hardness and indestructibility it would form a valuable building stone, but is little used. These properties also cause it to project in singularly sharp ridges and conical summits, of which the Paps of Jura are the best known.

The limestone associated with these older strata, though seldom in large masses, is yet widely spread. It has been wrought near Ballachulish and in various parts of Appin, in several places near the Crinan Canal, and along the whole peninsula of Kintyre as far as Campbeltown. The largest masses are found in some of the islands. Thus it covers the whole of Lismore and a large tract in the centre of Islay near Bowmore. A magnesian variety found on Iona, associated with serpentine, takes a good polish, and the red or flesh coloured marble of Tiree, often with embedded crystals of green hornblende, occurs in beds in the gneiss of that island.

Red sandstones, probably belonging to more than one period in the history of the earth, are found in different parts of Argyllshire. Some portions, resting conformably on the mica slate of Kintyre, may belong to the Torridon sandstone or Cambrian of the north-west coast, whilst other portions are of Devonian age. Some beds near Oban and on the Sound of Mull are probably Trias. True coal, a continuation of that in Ayrshire, has been wrought near Campbeltown. At various points on the coast of Mull, Morven, and Ardnamurchan, beds belonging to the Lias, Oolite, and even perhaps the Cretaceous formations, appear underlying the trap rocks. Though of much interest in a scientific point of view they have little influence on the general character of the county. More recent formations are the leaf beds, with remains of Miocene plants discovered in the trap tufa at Ardtunhead, in Mull, by the duke of Argyll in 1850. Raised beaches with fossil shells are also known on several parts of the coast, *e.g.*, at the Sound of Kerrera.

Of the igneous rocks, granite chiefly occurs in a large mass round the upper end of Loch Etive, extending south to Ben Cruachan near Loch Awe. Smaller masses appear near Ballachulish and at the Ross of Mull. In the latter place it has been extensively quarried and used for the magnificent lighthouse erected on the Skerry Vohr. Veins are common near these masses and in other places. Felspar porphyries in great variety of forms and colours, abound in Glencoe, in large masses in the mountains north of Loch Fyne below Inveraray, and again in Davar Island, and at other points near Campbeltown. Trap rocks—greenstones, dolerites, basalts, claystone porphyries, amygdaloids, and tufas—cover great extents both of the mainland and islands. In the west of Lorn they enclose the lower part of Loch Etive, stretching north to Loch Creran, and south nearly to Loch Awe and Loch Melfort. From this place, running westward through Kerrera, they form nine tenths of Mull and a wide tract on the opposite coast of Morven and Ardnamurchan. The islands of Muck, Eig, Rum, and Canna are more remote outliers of these formations to the north west, which also form the Treshinish Islands—Ulva, Gometra, and Staffa, with its far famed caves and beautiful columnar cliffs. From their relation to the stratified beds, these rocks evidently belong to a recent period in the history of the earth, many of them not older than the upper tertiary. At that time the west of this county, and especially the island of Mull, had formed the site of active volcanoes, rivalling in extent and activity any now known at least in Europe. The trap rocks in Kintyre connect them with those in central Scotland and the north of Ireland, whilst those in Skye are their continuation to the north.

Argyll is not rich in mineral products possessing an economic value. The lead mines of Strontian, in Sunart, produced in 1872 about twelve tons of lead ore. A vein of arsenical nickel was discovered in 1849 by the duke of Argyll near Inveraray. Fine specimens of the harmotome or cross-stone occur at Strontian, of the heliotrope or bloodstone in Rum, and of natrolite, siolezite, stilbite, and other zeolites in the trap-rocks of Mull, Morven, and Lorn.

Argyllshire was formerly interspersed with natural forests, remains of which—consisting chiefly of oak, ash, pine, and birch—are still visible in the mosses. But, owing to the clearance of the ground for the introduction of sheep, and the neglect of planting, the county is now remarkable for its want of wood, except in the neighbourhood of Inveraray, where there are extensive and flourishing plantations. A great part of the county is unfitted for agriculture; but many districts afford fine pasturage for the hill sheep; and some of the valleys—as Glendaruel—exhibit great fertility. The usual Scottish grains and roots are all more or less grown.

The chief branches of industry are the rearing of cattle and sheep, and the herring fishery. The cattle, though of small size, are equal, if not superior, to any other breed in the kingdom, and are in great demand in the markets of the south, to which they are sent in immense numbers. Dairy husbandry is practised to some extent in the southern parts of Kintyre, where there is a large proportion of arable land. In the higher tracts sheep have very advantageously been substituted for cattle. The black-faced is the species that is now almost universally reared.

Argyllshire is an attractive field for the sportsman, its deer forests, grouse-shootings, and salmon-fishings being among the best in Scotland. The rents derived from these sources have greatly increased during the last half century. As examples of these it may be stated, that the deer-forest of Blackmount is let for about £3000 a year, and the salmon-fishing of Ardnamurchan for upwards of £600. Loch Fyne is celebrated for its herring fishery; but during 1873 and 1874 the shoals have not advanced beyond the Sound of Kilbrannan.

The manufactures of Argyllshire are very limited, consisting solely of whisky and gunpowder; the former is produced at Campbeltown and in Islay, and the latter at Kames (Kyles of Bute), and at Melfort, Furnace, &c.

There were originally only military roads in Argyllshire, but these were gradually supplemented by others formed at the joint expense of Government (by a grant and maintenance) and the county, by means of assessment under the Road Commissioners—consequently there have never been any tolls. The Government grant was withdrawn about 1860, and the roads are now maintained solely by assessment, which is levied equally on landlords and tenants. By means of steamers there is regular intercourse between various parts of the extensive coast and the Western metropolis. In order to avoid the circuitous passage round the Mull of Kintyre the Crinan Canal was constructed, extending across the isthmus from Ardrishaig to Loch Crinan, a distance of 8 miles; and another canal unites Campbeltown with Dalavaddy. The Crinan is deep enough for vessels drawing 12 feet of water; its breadth at the surface is 66 feet, and at the bottom 30, and the passage is interrupted by fifteen locks. There are about twenty bank branches in the county. There are (1875) four weekly newspapers published in Argyllshire.

The antiquities of the county comprise monoliths, circles of standing stones, crannoges, and cairns. In almost all the burying grounds—as at Campbeltown, Keil, Soroby, Kilchousland—there are specimens of sculptured crosses and slabs, many of which are figured in *The Sculptured Stones of Scotland*, vol. ii., published by the Spalding Club, and *Archæological Sketches in Kintyre*, by Capt. T. P. White. For other subjects of archæological interest see *The Proc. of Antiq. Soc. of Scotland*, vols. iv. vi. viii. Besides the famous ecclesiastical remains at Iona, there are ruins of a Cistercian priory in Oronsay, and of a church founded by Somerlid at Saddel. Among castles may be mentioned Dunstaffnage, Ardtornish, Skipness, Kilchurn, Ardchonnel, Dunolly, Dunderaw, and Carrick.

The earliest recorded event in the history of Argyllshire is the settlement in the 4th or 5th century of a body of Irish Scots, under the leadership of Erc, who soon extended their power and established a dynasty. The most famous of their kings was Aidan, the friend of Columba. In the 8th century the district fell into the hands of Norwegian adventurers, and continued for five or six hundred years under Norwegian control, till the rise of a deliverer called Somerlid. Along with the Hebridean Isles, all the western parts of Argyll came to the Scottish monarchs by conquest in the 14th century. Some time after, Macdonald, the representative of this region, obtained leave from the Scottish crown to hold his possessions as a feudatory to that kingdom; but his turbulent spirit involved him and his family in repeated rebellions. These were at last punished by the forfeiture of the estates, which, along with the titles, were bestowed on the Campbells of Lochow, who have ever since retained them. Colin, second Lord Campbell, was created earl of Argyll in 1457; Archibald, second earl, fell at Flodden; Archibald, fourth earl, was the first nobleman in Scotland who declared himself a Protestant; Archibald, fifth earl, is famous as the supporter of Queen Mary; Archibald, the eighth earl, and other prominent holders of the titles, are noticed in the article immediately preceding. The tenth earl was raised to the dukedom of Argyll in 1701. The title is now (1875) held by a member of the same family, George Douglas Campbell, eighth duke.

Like other parts of the Highlands of Scotland, this county was the seat of several clans, of which the principal were the Campbells, the Macleans, the Stewarts of Appin, the Macdonalds of Glencoe, the Macquarries, and the Macdougalls; and the number of Campbells is still a striking feature of the personal nomenclature of the county. Gaelic is still to a considerable extent the vernacular dialect. The chief proprietors are the duke of Argyll and earl of Breadalbane, whose estates are respectively 168,000 and 179,000 acres in extent. The other principal estates, according to extent, are those of Poltalloch (183,000 acres), Islay (67,000), Jura (55,000), Ardnamurchan (55,000), Sunart (54,418), Kildalton (54,250), and Ardkinglass (51,670). The total number of owners of land possessing one acre or upwards was, in 1872–73, 581, and of owners who had less than one acre, 2283.

The valued rent of the county for 1874–75 is (exclusive of burghs and canals) £416,543. The valuation of the burghs is—Campbeltown, £20,624; Oban, £11,763; Inveraray, £3323. The county returns one member to parliament, and had in 1873–74 a constituency of 3010. Inveraray, Campbeltown, and Oban are contributory burghs to Ayr. It is governed by a lord-lieutenant and high-sheriff, about 48 deputy-lieutenants, a sheriff, and four substitutes. The justiciary circuit-court for the counties of Argyll and Bute is held at Inveraray in spring and autumn. Sheriff-courts are held at Inveraray, Tobermory, Campbeltown, and Fort William; and courts for small-debt actions, four times a year, at Oban, Lochgilphead, Dunoon, and Bowmore, in Islay. There are three prisons (at Campbeltown, Inveraray, and Tobermory), five poorhouses, an asylum at Lochgilphead for the Argyllshire and Bute district, sea-side homes for convalescents at Dunoon and at Kilmun, and a county militia barracks at Campbeltown. The ecclesiastical statistics of the county are as follows:—The Established Church of Scotland has a synod, 6 presbyteries, 40 parish and 18 *quoad sacra* churches, and 14 chapels of ease. The Free Church has a synod, 5 presbyteries, and 46 churches. The United Presbyterians have 8 churches connected with 2 presbyteries. The Episcopalians have a bishopric (Argyll and the Isles), a dean, and 17 clergymen; and the Roman Catholics have 5 priests. In 1871 there were 79·18 per cent. of the children between 5 and 13 years of age receiving education—Argyllshire in this respect standing above ten counties, but 7·36 below the highest, Perth. The population of Argyll has been decreasing since 1831, from the extensive emigration that has been going on, principally to Canada. The following is the state of its population since the commencement of the present century—1801, 81,277; 1811, 86,541; 1821, 97,316; 1831, 100,973, 1841, 97,371; 1851, 89,298; 1861, 79,724; 1871, 75,679.

ARGYRO-CASTRO (*Ergir Castri*), a town in the valley of the Drino, in the province of the Avlona, in Albania (*Epirus*). It has been variously identified with Hadrianopolis and Antigonea, and is supposed to preserve the name of the ancient Argyrini. It is the focus of the Mussulman aristocracy of Epirus, and contains the ruins of an imposing castellated fort. There is a considerable manufacture of a fine kind of snuff, called *Fuli*. Hobhouse and Holland estimated the inhabitants at 20,000; but in 1814 the town was almost depopulated by a plague, and the number has sunk to 6000.

ARGYROPULUS, or ARGYROPULO, JOHN, a learned Greek who lived during the 15th century. He appears to have crossed over to Italy about 1434, and in 1442 was made rector of the university at Padua. About 1456 he was invited to Florence by some of the Medici, and was there appointed professor of Greek in the university. Fifteen years after he removed to Rome, where he continued to act as professor of Greek till his death, which took place probably soon after 1489. His principal works were translations of the following portions of Aristotle:—*Categories*, *De Interpret.*, *Analyt. Post.*, *Physics*, *De Cœlo*, *De Anima*, *Metaphysics*, *Nicom. Ethics*, *Politics*. His only original published writing is an *Expositio Ethicorum Aristotelis*. Several of his writings exist still in manuscript.

ARIADNE (Ἀριάδνη = Ἀριάγνη, the Cretan form of ἁγνός being ἀδνός), in *Greek Mythology*, a personification of the return of Spring, at which period took place, it was believed, Ariadne's marriage with Dionysos (Bacchus), who also, after an absence throughout the winter, was thought to return amid the rejoicings of spring. This marriage was the great feature in her worship, which appears to have originated in Crete, and to have been mostly confined to that island and to Naxus, where annually it was celebrated by the people with dances and a festival called *Theodaisia*. But though married to Dionysos, and sometimes called his wife (ἄκοιτις, Hesiod, *Theogony*, 948), she did not generally appear in this character. On the contrary, in the *Odyssey* (xi. 321–325), it is said that Artemis slew her, with the consent of Dionysos, at Dia (near Cnossus), before she could reach Athens with Theseus. Her death would thus seem a punishment for her infidelity. But in the current legend her connection with Dionysos did not begin till he found her asleep in Naxus after her despair at being abandoned by Theseus, with whom she had escaped from Crete after assisting him against her father, the fierce Minos, to slay the Minotaur. She had given Theseus a clue by means of which, while she retained the other end, he could find his way through the labyrinth, in which he had to fight that monster with human body and bull's head. In the *Iliad* (xviii. 591) she is spoken of as the fair-haired Ariadne, for whom Dædalus had skilfully made a dancing-place (χορός) in Cnossus, and it is probable that the reference here is to the dances with which her marriage was celebrated in Crete. Possibly also the description of her as a daughter of Minos, which is as early as the *Odyssey* (xi. 321), was not founded in the belief of the Cretans, to whom she was a goddess, but arose elsewhere from observation of her peculiarly local character. Another form of her name in Crete, Ἀριδήλα (= φανερά), refers to her as a being connected with the return of a bright season in nature. In works of art her marriage with Dionysos, and her abandonment by Theseus in Naxus, are known to have been frequently the subject of representation. Examples of both still exist on the vases and in mural paintings. The scene where she holds the clue to Theseus occurs on a very early vase in the British Museum.

ARIANO, a town of Italy, in the province of Avellino, about 38 miles N.E. of Naples, situated 2500 feet above the level of the sea, on a steep and rocky hill, between the rivers Calore and Tribaldo. Founded by the Greek governors of Apulia, it continued to be an important military post for several centuries, and was frequently taken and retaken during the various dynastic struggles of southern Italy. A parliament was held here by Roger I. in 1140, and in 1648 the town was pillaged by the duke of Guise. It is still a bishop's see, and the chief town of a *circondario*, with a cathedral, and a large number of churches. Earthenware is manufactured, and there is some trade in wine and butter. The most peculiar feature of the town is the multitude of troglodytic dwellings, in which the poorer classes reside. The district is highly volcanic, and the town has suffered severely from earthquakes (1456, 1732), and only 7 miles distant is the lake of Amsanctus (*Mofete*), remarkable for its suffocating exhalations. Population, 14,347. (See Vitate, *Storia della Città d' Ariano*, Rome, 1794.)

ARIANS. See ARIUS.

ARIAS MONTANUS, BENEDICTUS, one of the most learned Oriental scholars of his time, and the editor of the Antwerp Polyglott, was born at Frescenal de la Sierra, in Estremadura, in 1527. After studying at the university of Alcala, he joined the Benedictine order. In 1562 he accompanied the bishop of Segovia to the Council of Trent. After a few years spent in retirement at Aracena he went to Antwerp, at the request of Philip II., to edit the Polyglott Bible that had been projected by Plantin the printer. The work appeared in 8 volumes folio, between 1568 and 1573. The Jesuits founded on it several charges of heresy against Arias, from which he succeeded in clearing himself, though only after several visits to Rome. He declined the offer of a bishopric from the king, but after some time spent in retirement at Aracena, became librarian at the Escorial. The closing years of his life were passed at Seville, where he died in 1598.

ARICA, a sea-port of Peru, in the department of Moquegua, in lat. 18° 28′ S., and long. 70° 10′ W. It was at one time a city of 30,000 inhabitants, and had a large export trade in wool, copper, and silver; but in consequence of civil war (1821) and earthquakes (1832, 1868), it has greatly declined; of late, however, it has shared in the general revival of Peru. The Government has taken measures for the improvement of the port, which is connected by railway with Tacna, about 38 miles inland, where many of the merchants reside. Population, about 4000.

ARIEGE, a department of France, bounded on the S. by Spain, W. by Haute-Garonne, N.E. by Aude, and S.E. by Pyrénées Orientales. It embraces the old countship of Foix, and a portion of Languedoc and Gascony, and has an area of 1889 square miles. The southern part is occupied by the Pyrenees, which here contain some of the highest peaks in France, as, Pic d'Estats (which is 10,811 feet above the level of the sea), Montcalm (10,512), Font-argente, and Montleon. Communication with Spain is afforded by a large number of *ports* or *cols*, which are, however, for the most part difficult paths, and only practicable for a few months in the year. The northern portion consists of a kind of plateau, broken by beautiful and fertile valleys. Ariège belongs to the Garonne basin, and is watered by the Salat, the Arize, and the Ariége, with their tributaries. The climate is mild in the south, but naturally very severe among the mountains. The country affords excellent pasture, and a considerable number of cattle, sheep, and swine are reared, but there is little arable land, and what exists is broken up into small crofts. There is abundance of minerals—lead, copper, manganese, and especially iron, being largely obtained. Alum is found at Mas-d'Azil, alabaster among the mountains, building-stone at Pamiers, marble at Belesta, &c. Warm mineral springs are common. The preparation of woollen cloths, the forging of iron, and manufacture of steel are the principal industries, while soap, paper, and wooden wares are likewise produced. Among the celebrated men of the department are Gaston de Foix, Pope Benedict XII., and Pierre Bayle. The chief town is Foix, the arrondissements, Foix, St Girons, and Pamiers. Population, 244,798.

ARION (pronounced *Ari'on*), a celebrated poet and cithara player, a native of Methymna, in Lesbos. As he is said to have been the friend of Periander, tyrant of Corinth, he must have flourished about 625 B.C. Several of the ancients ascribe to him the invention of the dithyramb and of dithyrambic poetry; it is probable, however, that his real service was confined to the organisation of that verse, and the conversion of it from a mere drunken song, used in the Bacchic revels, to a measured antistrophic hymn, sung by a trained body of performers. Nothing more is known of the life of Arion, with the exception of the beautiful story first told by Herodotus, and afterwards elaborated and embellished by many subsequent writers. According to Herodotus, Arion had become desirous of exhibiting his skill in foreign countries, and, leaving Corinth, had travelled through Sicily and parts of Italy, where he gained great fame, and amassed a large sum of money. At Tarentum he embarked for his homeward voyage in a ship belonging to Corinth. The sight of his treasure roused the cupidity of the sailors, who resolved to possess themselves of it by putting him to death. In answer to his entreaties that they would spare his life, they insisted that he should either die by his own hand on shipboard, or cast himself into the sea. Arion chose the latter, and as a last favour begged permission to sing a parting song. The sailors, desirous of hearing so famous a musician, consented, and the poet, standing on the deck of the ship, arrayed in the rich garments in which he was accustomed to be habited, sang a dirge accompanied by his lyre. He then threw himself overboard, but instead of perishing, as the sailors imagined, he was miraculously borne up in safety by a dolphin, supposed to have been charmed by the music. Thus he was conveyed to Tænarus, whence he proceeded to Corinth, arriving before the ship from Tarentum. Immediately on his arrival Arion related his story to Periander, the tyrant of Corinth, who was at first incredulous, but eventually learned the truth by a stratagem. Summoning the sailors, he demanded what had become of the poet. They affirmed that he had remained behind at Tarentum; upon which they were suddenly confronted by Arion himself, arrayed in the same garments in which he had leapt overboard. The sailors confessed their guilt, and were punished. Herodotus and Pausanias both refer to a brass figure at Tænarus, which was supposed to represent Arion seated on the dolphin's back. But this story is only one of several in which the dolphin appears as saving the lives of favoured heroes. Among others, it is curious that Taras, the mythical founder of Tarentum, is said to have been conveyed in this manner from Tænarus to Tarentum. On Tarentine coins a man and dolphin appear, and hence it may be thought that the monument at Tænarus represented Taras, and not Arion. From the frequent appearance of the dolphin in mythical stories of voyages, it has been conjectured that it was looked upon as in some way the preserver of those at sea, and votive offerings would therefore be given to it by those who had escaped the perils of the deep. At the same time, the connection of Apollo with the dolphin must not be forgotten. Under this form the god appeared when he founded the celebrated oracle at Delphi, the name of which commemorates the circumstance. He was also the god of music, the special preserver of poets, and to him the lyre was sacred. The story of Arion seems, therefore, to be but one of the many and varied forms of the wide-spread myth of Apollo. Among the numerous modern versions of it, particular mention may be made of the pretty *Romanze* "Arion" by A. W. Schlegel.

ARIOSTO, LODOVICO, one of the greatest poets of Italy, was born at Reggio, in Lombardy, on the 8th Sept. 1474. His father was Niccolo Ariosto, commander of the citadel of Reggio. He showed a strong inclination to poetry from his earliest years, but was obliged by his father to study the law—a pursuit in which he lost five of the best years of his life. Allowed at last to follow his inclination, he applied himself to the study of the classics under Gregorio da Spoleti. But after a short time, during which he read the best Latin authors, he was deprived of his teacher by Gregorio's removal to France as tutor of Prince Sforza. Ariosto thus lost the opportunity of learning Greek, as he intended. His father dying soon after, he was compelled to forego his literary occupations to undertake the management of the family, whose affairs were embarrassed, and to provide for his nine brothers and sisters, one of whom was a cripple. He wrote, however, about this time some comedies in prose and a few lyrical pieces. Some of these attracted the notice of the cardinal Ippolito of Este, who took the young poet under his patronage, and appointed him one of the gentlemen of his household. This prince usurped the character of a patron of literature, whilst the only reward which the poet received for having dedicated to him the *Orlando Furioso*, was the question, "Where did you find so many stories, Master Ludovic?" The poet himself tells us that the cardinal was ungrateful; deplores the time which he spent under his yoke; and adds, that if he received some niggardly pension, it was not to reward him for his poetry, which the prelate despised, but to make some just compensation for the poet's running like a messenger, with risk of his life, at his eminence's pleasure. Nor was even this miserable pittance regularly paid during the period that the poet enjoyed it. The cardinal went to Hungary in 1518, and wished Ariosto to accompany him. The poet excused himself, pleading ill health, his love of study, the care of his private affairs, and the age of his mother, whom it would have been disgraceful to leave. His excuses were not received, and even an interview was denied him. Ariosto then boldly said, that if his eminence thought to have bought a slave by assigning him the scanty pension of 75 crowns a year, he was mistaken and might withdraw his boon—which it seems the cardinal did.

The cardinal's brother, Alphonso, duke of Ferrara, now took the poet under his patronage. This was but an act of simple justice, Ariosto having already distinguished himself as a diplomatist, chiefly on the occasion of two visits to Rome as ambassador to Pope Julius II. The fatigue of one of these hurried journeys brought on a complaint from which he never recovered; and on his second mission he was nearly killed by order of the violent Pope, who happened at the time to be much incensed against the duke of Ferrara. On account of the war, his salary of only 84 crowns a year was suspended, and it was withdrawn altogether after the peace; in consequence of which Ariosto asked the duke either to provide for him, or to allow him to seek employment elsewhere. A province, situated on the wildest heights of the Apennines, being then without a governor, Ariosto received the appointment, which he held for three years. The office was no sinecure. The province was distracted by factions and banditti, the governor had not the requisite means to enforce his authority, and the duke did little to support his minister. Yet it is said that Ariosto's government satisfied both the sovereign and the people confided to his care; and a story is added of his having, when walking out alone, fallen in with a party of banditti, whose chief on discovering that his captive was the author of *Orlando Furioso*, humbly apologised for not having immediately shown him the respect which was due to his rank. Although he had little reason to be satisfied with his office, he refused an embassy to Pope Clement VII. offered to him by the secretary of the duke, and spent the remainder of his life at Ferrara, writing comedies, superintending their performance, as well as the construction of a theatre, and correcting his *Orlando Furioso*, of which the complete edition was published only a year before his death. He died of consumption on the 6th of June 1533.

That Ariosto was honoured and respected by the first men of his age is a fact; that most of the princes of Italy showed him great partiality is equally true; but it is not less so that their patronage was limited to kind words. It is not known that he ever received any substantial mark of their love for literature: he lived and died poor. He proudly wrote on the entrance of a house built by himself,

> "Parva, sed apta mihi, sed nulli obnoxia, sed non
> Sordida, parta meo sed tamen ære domus;"

which serves to show the incorrectness of the assertion of flatterers, followed by Tiraboschi, that the duke of Ferrara built that house for him. The only one who seems to have given anything to Ariosto as a reward for his poetical talent was the Marquess del Vasto, who assigned him an annuity of 100 crowns on the revenues of Casteleone, in Lombardy; but it was only paid, if ever, from the end of 1531. That he was crowned as poet by Charles V. seems untrue, although a diploma may have been issued to that effect by the emperor.

The character of Ariosto seems to have been fully and justly delineated by Gabrielle, his brother:—

> Ornabat pietas et grata modestia Vatem,
> Sancta fides, dictique memor, munitaque recto
> Justitia, et nullo patientia victa labore,
> Et constans virtus animi, et clementia mitis,
> Ambitione procul pulsâ, fastûsque tumore."

His satires, in which we see him before us such as he was, show that there was no flattery in this portrait. In these compositions we are struck with the noble independence of the poet. He loved liberty with a most jealous fondness. His disposition was changeable withal, as he himself very frankly confesses in his Latin verses, as well as in the satires.

> "Hoc olim ingenio vitales hausimus auras,
> Multa cito ut placeant, displicitura brevi.
> Non in amore modo mens hæc, sed in omnibus impar
> Ipsa sibi longa non retinenda mora."

Hence he never would bind himself, either by going into orders, or by marrying, till towards the end of his life, when he espoused Alessandra, widow of Tito Strozzi. He had no issue by his wife, but he left two natural sons by different mothers.

His Latin poems do not perhaps deserve to be noticed: in the age of Flaminio, Vida, Fracastoro, and Sannazzaro, better things were due from a poet like Ariosto. His lyrical compositions show the poet, although they do not seem worthy of his powers. His comedies, of which he wrote four, besides one which he left unfinished, are avowedly imitated from Plautus and Terence; and although native critics may admire in them the elegance of the diction, the liveliness of the dialogue, and the novelty of some scenes, few will feel interest either in the subject or in the characters, and none would now approve the immoral passages by which they are disfigured, however grateful these might be to the audiences and patrons of theatrical representations in Ariosto's own day.

Of all the works of Ariosto, the most solid monument of his fame is the *Orlando Furioso*, the extraordinary merits of which have cast into oblivion the numberless romance poems which inundated Italy during the 15th, 16th, and 17th centuries.

The popularity which an earlier poem on the same theme, *Orlando Innamorato*, by Boiardo, enjoyed in Ariosto's time, cannot be well conceived, now that the enthusiasm of the Crusades, and the interest which was attached to a war against the Moslems, have passed away. Boiardo wrote and read his poem at the court of Ferrara, but died before he was able to finish it. Many poets undertook the difficult task of its completion; but it was reserved for Ariosto both to finish and to surpass his original. Boiardo did not, perhaps, yield to Ariosto either in vigour or in richness of imagination, but he lived in a less refined age, and died before he was able to recast or even finish the poetical romance which he had written under the impulse of his exuberant fancy. Ariosto, on the other hand, united to a powerful imagination an elegant and cultivated taste. He began to write his great poem about 1503, and after having consulted the first men of the age of Leo X., he published it in 1516, in only 40 cantos (extended afterwards to 46); and up to the moment of his death never ceased to correct and improve both the subject and the style. It is in this latter quality that he excels, and for which he had assigned him the name of *Divino Lodovico*. Even when he jests, he never compromises his dignity; and in pathetic description or narrative, he excites the reader's deepest feelings. In his machinery he displays a vivacity of fancy with which no other poet can vie; but he never lets his fancy carry him so far as to omit to employ, with an art peculiar to himself, those simple and natural pencil-strokes which, by imparting to the most extraordinary feats a colour of reality, satisfy the reason without disenchanting the imagination. The death of Zerbino, the complaints of Isabella, the effects of discord among the Saracens, the flight of Astolfo to the moon, the passion which causes Orlando's madness, teem with beauties of every variety. The supposition that the poem is not connected throughout is wholly unfounded; there is a connection which, with a little attention, will become evident. The love of Ruggero and Bradamante forms the main subject of the *Furioso;* every part of it, except some episodes, depends upon this subject; and the poem ends with their marriage.

The first complete edition of the *Orlando Furioso* was published at Ferrara in 1532, as noted above. The edition of Morali (Milan, 1818) follows the text of the 1532 edition with great correctness. Of editions published in England, those of Baskerville (Birmingham, 1773), and Panizzi (London, 1834), are the most important. The indifferent translations into English of Harrington and Hoole have been superseded by the spirited rendering of Rose.

ARISTÆUS (from ἄριστος, best), a divinity whose worship was widely spread throughout Greece, but concerning whose origin and career the myths are somewhat obscure. The account most generally received connects him specially with Thessaly. Apollo carried off from Mount Pelion the nymph Cyrene, daughter or granddaughter of Peneus (Peneius), and conveyed her to Libya, where she gave birth to Aristæus. From this circumstance the town of Cyrene took its name. The child was at first handed over to the care of the Hours, or, according to another version, to the nymph Melissa and the centaur Chiron. He afterwards left Libya and came to Thebes, where he received instruction from the Muses in the arts of healing and prophecy, and married Autonoe, daughter of Cadmus, by whom he had several children, among others, the unfortunate Actæon. He is said to have visited Ceos, where, by erecting a temple to Zeus Icmæus (the giver of moisture), he freed the inhabitants from a terrible drought. The islanders worshipped him, and occasionally identified him with Zeus, calling him Zeus Aristæus. After travelling through many of the Ægean islands, through Sicily, Sardinia, and Magna Græcia, everywhere conferring benefits and receiving divine honours, Aristæus came to Thrace, where he was initiated into the mysteries of Dionysos, and finally disappeared near Mt. Hæmus. While in Thrace he is said to have caused the death of Eurydice, who was bitten by a snake while fleeing from him. Aristæus was essentially a benevolent deity; he was worshipped as the first who introduced the cultivation of bees, and of the vine and olive; he was the protector of herdsmen and hunters (and was therefore called νόμιος and ἀγρεύς); he warded off the evil effects of the dog-star; he possessed the arts of healing and prophecy. In ancient sculptures and coins he is represented as a young man, habited like a shepherd, and sometimes carrying a sheep on his shoulders. Occasionally he is accompanied by a bee or a dove.

ARISTANDER, the favourite soothsayer of Alexander the Great, who consulted him on all occasions. After the death of the monarch, when his body had lain unburied for thirty days, Aristander procured its burial by foretelling that the country in which it was interred would be the most prosperous in the world. He is probably the author of a work on prodigies, which is referred to by Pliny and Lucian.

ARISTARCHUS, of Samothrace, the most famous of the Greek grammarians and critics, flourished about 160 B.C. He spent the greater part of his life at Alexandria, where he studied in the school of Aristophanes of Byzantium. He acquired the highest reputation for critical skill, and founded a school for philology, which long flourished at Alexandria and afterwards at Rome. Ptolemy V. (Epiphanes) and Ptolemy VII. (Physcon) are said to have been among his pupils. During the reign of Physcon, who exercised great cruelty towards the learned men in his capital, Aristarchus withdrew to the isle of Cyprus, where, it is said, he suffered from dropsy, and voluntarily starved himself to death. Aristarchus commented on Pindar, Archilochus, Æschylus, Sophocles, Aristophanes, and Ion: but his great fame rests on his recension of Homer. His principal object was to secure a thoroughly accurate text, and he carefully removed all supposed interpolations, marking with an obelus lines considered by him to be spurious, and with an asterisk those that seemed particularly beautiful. His edition was highly valued, and has been the basis of all subsequent recensions. The criticism of Aristarchus was not merely verbal; he attended carefully to metre; he arranged the Iliad and Odyssey in books, as we now have them; and he wrote elaborate commentaries, entering into all questions of mythology and geography. He is also said to have been the first to apply accents to the Homeric poems. Of his numerous commentaries, and his longer treatises, particularly that *On Analogy*, only a few fragments have come down through the later scholiasts. See Matthesius, *Disputatio de Aristarcho Grammatico;* Villoisson, *Proleg. ad. Hom. Il.;* F. A. Wolf, *Proleg. in Hom.;* Lehrs, *De Aristarchi Studiis Homericis.*

ARISTARCHUS, a Greek astronomer of Samos, who lived about 280–264 B.C. He is famous as being the first to maintain that the earth moves round the sun. No mention, indeed, is made of this doctrine in his only surviving work, Περὶ μεγεθῶν καὶ ἀποστημάτων, which treats of the *Magnitudes and Distances of the Sun and Moon;* but Archimedes, in his *Arenarius*, quotes from a work written by Aristarchus as a refutation of astrology, which renders it certain that the Samian astronomer had clearly anticipated the grand discovery of Copernicus. That the latter was unacquainted with the doctrine of Aristarchus is equally certain from the fact that the *editio princeps* of Archimedes had not appeared till after Copernicus's death. The method given by Aristarchus of estimating the relative lunar and solar distances is geometrically correct, though the instrumental means of observation at his command rendered his data erroneous. His work has been published in Latin by G. Valla, Venice, 1498, folio; in Greek and Latin, with the commentary of Pappus, by Wallis, Oxford, 1688; and in a French translation by Fortia d'Urban, Paris, 1823, 8vo. See Delambre, *Hist. de l'astronomie ancienne.*

ARISTEAS, a somewhat mythical personage, said to have been a native of Proconnesus, an island in the Propontis. He travelled extensively, under the inspiration of Apollo, through the countries north and east of the Euxine, and visited the Hyperboreans, Issedines, and Arimaspi. His date is uncertain; Suidas places him in the period of Crœsus and Cyrus, others before the time of Homer. Herodotus and those who write of him regarded him as a magician, whose soul could enter and leave his body at pleasure. At Proconnesus he is said to have entered a shop and died there. While the owner of the shop was informing his family of the event, a stranger from Cyzicus told them that he had met and spoken with Aristeas. On going to the shop they did not find him, either dead or alive. Seven years after, he returned, wrote his poem, the Arimaspea, and again disappeared; 340 years later, he is said to have appeared at Metapontum, and commanded the inhabitants to raise an altar to Apollo, and a statue to himself. Of his poem, about a dozen lines are preserved by Longinus and Tzetzes. It appears to have contained geographical details. Some writers—Dionysius of Halicarnassus, for instance—do not believe that Aristeas was the author of this poem.

ARISTIDES, surnamed the Just, was the son of Lysimachus, a native of Athens, of the tribe Antiochis. His family appears to have been of noble descent; at least it is known that Callias, the torch-bearer at the Eleusinian mysteries, and reputedly the wealthiest man in Athens, was a cousin or near kinsman. Plutarch maintains, in opposition to Demetrius Phalereus, that Aristides was very poor, and never enriched himself at the expense of the state. His poverty, however, seems scarcely reconcilable with the fact that he was made archon at a time when the possession of a certain amount of property was an indispensable qualification for that office. But extremely little is known of his early life. So far as political tendencies went, he had been a companion and follower of Clisthenes, and it is also told that he had a great veneration for the character and legislation of Lycurgus. He, therefore, naturally took the aristocratic side in questions of state policy, and consequently found himself incessantly opposed to the great democratic leader, Themistocles. Plutarch relates many anecdotes of the constant opposition between the two, but in several points his account must be inaccurate.

The first certain appearance of Aristides in history was at the battle of Marathon, 490 B.C., where he was one of the ten generals, and led his own tribe, Antiochis. He is said to have been second in command to Miltiades. According to custom each of the ten generals had supreme command of the whole army for one day; Aristides saw the disadvantages of this system, which totally prevented any fixed plan being carried out, and by his advice and example prevailed on the other generals to relinquish their right in favour of Miltiades. This prudent measure contributed largely to the success of the battle, in which also, according to Plutarch, much was due to the valour of Aristides. He was left with one tribe to collect the spoil from the field of battle, while Miltiades marched to Athens to protect the city from the Persian fleet. He discharged the duty intrusted to him with the most scrupulous honesty. Next year he was made archon eponymus, and his reputation for justice appears to have been increased by the manner in which he performed the duties of his office. But his great rival, Themistocles, who had been meanwhile increasing his own power, grew jealous, and gradually raised a strong feeling against him by representing how dangerous it was for a democracy that any individual should be allowed to gain such influence as that of Aristides. The Athenians, uneasy at this idea, banished him by ostracism in 483. It is said that, on this occasion, an ignorant fellow, who did not know Aristides, came up to him, and, giving him his shell, desired him to write upon it the name of Aristides. The latter asked in surprise if Aristides had done him any wrong. "No," was the reply, "and I do not even know him, but it irritates me to hear him everywhere called *the just*." Aristides made no answer, but took the shell and wrote his own name on it.

On the night before the battle of Salamis, Aristides, who was still in exile, made a perilous journey through the enemy's fleet, and reached the tent of Themistocles. He told him that he had come to bury in oblivion their former differences; that he had learned his plan for giving battle to the Persian fleet in the narrow straits of Salamis, and highly approved of it; and that he would assist him to the utmost of his ability. By his influence the other generals were induced to assent to the plans of Themistocles, of whom they were somewhat jealous. On the day of battle, Aristides collected some Athenian volunteers, and made a descent on the little island of Psyttalea, which was filled with the forces of the enemy. These he routed and almost annihilated. After the victory of Salamis he dissuaded Themistocles from his ambitious plan of conquering Asia by destroying the bridge which the Persians had built over the Hellespont, and thereby cutting off their communications.

About this time his sentence of exile appears to have been revoked, for in 479 he was general of the Athenians in the campaign against Mardonius, and shared with Pausanias the glory of the victory at Platæa. By his prudent counsels before the battle, he settled a dangerous dispute with the Tegetæ; and after the victory, when the Athenians and Lacedæmonians were contending as to the right of erecting the trophy, he prevailed on the Athenians to give up their claim. The Lacedæmonians immediately followed this example, and the honours of the day were given to the Platæans. He also instituted yearly sacrifices and quinquennial games at Platæa, to celebrate the victory over the barbarians and the liberation of Greece. On his return to Athens, Aristides introduced the famous measure by which the archonship was thrown open to all classes of citizens. In 477, he was sent along with Cimon, over whom he had great influence, to take command of the Athenian contingent, under the general command of Pausanias the Lacedæmonian. The haughtiness and oppressive conduct of the Spartans had disgusted the allies, who were completely won over by the mildness and prudence of Aristides and Cimon. In a body the allied Greeks threw off the hegemony of Sparta, and formed a confederation under the Athenians. To Aristides was committed the task of drawing up the laws for this confederacy, and settling the amount of tribute which should be paid by each state. This duty he discharged to the complete satisfaction of the allies, who were delighted to be assessed at only 460 talents. The first instalment of the tax was paid into the national treasury, then situated on the sacred island of Delos, but afterwards transferred to Athens, a measure which Aristides is said to have declared unjust but expedient.

The time and place of his death are uncertain. It is known, at least, that he survived the banishment of Themistocles, for his generous conduct towards his fallen rival is commemorated by Plutarch. He died, probably, about 468 B.C., according to some at Athens, according to others at Pontus. He is said to have died in such poverty that he did not leave enough to defray his funeral expenses, but had a tomb erected to him with funds from the public treasury. This tomb at Phalerum was still to be seen in the time of Plutarch. His daughters received marriage portions from the state, and his son, Lysimachus, was granted a sum of money and a portion of land. Such was the respect of the Athenians for the memory of their great statesman, that even his remote descendants are said to have received assistance from the public treasury.

ARISTIDES, ÆLIUS, surnamed Theodorus, a distinguished Greek rhetorician or sophist, was the son of Eudæmon, a priest of Zeus, and was born at Adriani, in Mysia. The date of his birth is given by some as 129 A.D., by others, with more probability, as 117. He studied with great assiduity, and early manifested an uncommon aptitude for all that pertained to the art of rhetoric. He travelled extensively through Greece, Italy, Egypt, and Asia, and acquired such renown for eloquence that monuments were erected to him in several of the towns through which he passed. A record of his journeys has been preserved by himself, and his vanity appears to have been increased to an inordinate extent by his success. Shortly after his return to Italy, he was seized with a peculiar illness, which lasted for 13 years, and the nature of which has been the subject of some speculation. It is described very fully in his six *Sacred Discourses*, along with a mass of details regarding visions, dreams, and wonderful cures. His account of these cures has excited considerable attention, from the similarity between them and the effects produced by Mesmerism or Hypnotism, *i.e.*, nervous sleep. Aristides meanwhile had settled at Smyrna, whither he had gone for the sake of his health. In 178, when the city was partially destroyed by an earthquake, he wrote an eloquent account of the misfortune to the Emperor Aurelius, with whom he was a great favourite, and prevailed on him to give assistance to the citizens. The Smyrnæans, out of gratitude for this service, called Aristides the founder of their city, and erected a brazen statue to him. He declined the other honours which they would have heaped upon him, and would only accept the office of priest of Æsculapius, which he held till his death, about 189 A.D.

The extant works of Aristides consist of two small and unimportant treatises on rhetoric, and of fifty-five orations or declamations. In several of these he selects the same subjects as had been treated by Demosthenes and Isocrates, and puts himself in direct competition with them. His contemporaries ventured to compare him with Demosthenes, but modern criticism does not confirm this judgment. The style of Aristides is good, sometimes terse and elegant, but occasionally laboured, and there is a total want of the vigorous energy of thought and practical skill that give so much power to the orations of Demosthenes. No doubt this is in great measure due to the fact that the subjects selected by Aristides were to him fictitious, and that, consequently, his whole attention must have been concentrated on the diction and manner of treatment; in the cause itself he could have had no living interest. A complete edition of his works was published by Dindorf, *Aristidis Opera*, 3 vols., Leipsic, 1829.

ARISTIDES of THEBES, a celebrated Greek painter, was an older contemporary of Apelles, and flourished about 350 B.C. He is said by Pliny to have been the first to express in his paintings character and passion; but this is probably an exaggeration. Several of his paintings are recorded in which there was manifested extraordinary mastery of expression. His colouring is said by Pliny to have been hard.

ARISTIDES, QUINTILIANUS, author of a valuable treatise on music, lived probably in the first century of our era. According to Meibomius, in whose collection (*Antiq. Musicæ Auc. Septem*, 1652) this work is printed, it contains everything on music that is to be found in antiquity.

ARISTIPPUS, the founder of the Cyrenaic school of philosophy, was the son of Aritadas, a wealthy merchant of Cyrene, in Africa. Nothing is known of the early part of his life, but he appears to have been sent by his father on a voyage to Greece, and while there, attending the Olympic games, he was attracted by the fame of the Socratic teaching. He immediately proceeded to Athens, united himself to the circle of followers who surrounded Socrates, and continued with him till his death in 399. He did not, however, accept without essential modification the teaching of his master, and his conduct, in many points, was displeasing both to Socrates and to other members of the Socratic band. He had probably brought with him from the wealthy city of Cyrene habits of luxury and ostentation, which contrasted forcibly with the homely and temperate life of his master. Xenophon, in the *Memorabilia*, reports his conversation on the nature of temperance, in which he defends his life of ease and self-indulgence. Plato also somewhat significantly states that he was absent in the island of Ægina on the day when Socrates died. Another feature of his character, which rendered Aristippus objectionable to the other Socratics, was his tendency to adopt the theory and practice of the Sophists, among whom he is expressly included by Aristotle (*Met.*, ii. 2). It is more than probable that in Cyrene he had been already introduced to the doctrines of Protagoras, of whose influence his own theory shows manifest traces. We are further told that he opened his school before the death of Socrates, who blamed him for receiving payment from his scholars. This story is probably inaccurate as to the time when he began to teach, but it is undoubtedly true that he took money for his lectures, and defended the practice. Aristippus resembled the Sophists in another particular; like them, he avoided the duties and ties of citizenship by wandering from city to city. He was a professed cosmopolitan. The records of his travels, particularly of his visit or visits to the court of Syracuse, and his hostile relations with Plato there, are not in all points consistent, and rest on but slender authority. He appears to have settled finally in his native city, and seems to have died there. Although nothing is known with certainty as to the dates of his birth and death, 435 B.C. for the one, and about 356 B.C. for the other, may be accepted as probably accurate. The life of Aristippus is the best exemplification of his principles. True temperance, according to him, consists not in abstaining from pleasure, but in being able to enjoy it with moderation. He therefore indulged in good living, rich clothing, splendid dwellings, and in the society of the accomplished hetæræ. But in all these pleasures he remained thoroughly master of himself; he possessed them, and was not possessed by them. At any moment he could relinquish pleasure, for he had attained an equanimity that rendered him happy under any circumstances. To make the most of life, reasonably to enjoy the present moment, and to drive off care, reflection, and forethought, were the practical precepts by which he guided himself. As might naturally be expected, Aristippus left no definite system of philosophy; indeed, according to some accounts, he wrote nothing at all. Diogenes Laërtius certainly gives a list of works ascribed to him, but some of these were no doubt spurious, and none have survived. His daughter Arete, who had received the spirit of his teaching, continued the school after his death, and in turn instructed her son, the younger Aristippus (hence called μητροδίδακτος), to whom is attributed the systematic representation of the Cyrenaic doctrines, the fundamental principles of which, however, are due to the elder Aristippus.

In the Socratic theory of morals, virtue had appeared as the only human good, and reason as the indispensable condition of right action; but there was at the same time a utilitarian side to this teaching. Ethical virtues had been tested by their consequences; proof of the virtuous quality of an action had been drawn from its tendency to give pleasure; happiness or utility had been, in a certain sense, laid down as the end of action. This one-sided aspect of the Socratic theory was accepted by Aristippus, and by him carried out to its full extent. He refused altogether to consider those speculative elements, which, though in some degree rejected by Socrates himself, were nevertheless inherent in the Socratic system. Logic and Physics he thought unnecessary, for they contained nothing which bore upon the end of action, and for the same reason, as Aristotle tells us, he rejected mathematical study. But although Logic and Physics, as separate disciplines, received no attention from the Cyrenaics, yet they were admitted as supports to their ethical theory. According to Aristippus, knowledge is sensible perception; all that we know of anything is the impression made by it on us. These impressions are motions,—changes in our mental states; and each mental state is a purely subjective phenomenon, from which we can deduce nothing as to the constitution of external reality. Nor can we compare our knowledge with that of others; each one's sensations are peculiarly his own, and can be known only by himself. General names or conceptions, and, consequently, general propositions or truths, are meaningless and absurd. Individual feeling is the sole criterion of truth. From this it follows at once that such feeling is the only means by which we can determine our actions; feeling becomes the standard both of truth and of action. Now the only difference among feelings, in their relation to action, is their pleasurable or painful quality. The change effected in us by any object is either a violent, a gentle, or a perfectly tranquil motion. The first is painful, the second pleasant, the third indifferent. The end of life, as is manifest also from experience, is the attainment of pleasure, which must be positive or real, not merely absence of pain, as the Epicureans afterwards held. Further, future pleasure, as a gentle motion not yet effected, and past pleasure, as a gentle motion completed and done, cannot possibly enter into our estimate of happiness. Immediate gratification, the pleasure of the moment (μονόχρονος), is the end of life; real happiness consists of a succession of moments of intense pleasure. The conception of a life in which, on the whole, pain is over-balanced by pleasure, may certainly be formed, but can never furnish a satisfactory end of action. Varieties of pleasure were, of course, admitted by Aristippus, but his decided opinion seems to have been that bodily pleasures and pains are the most potent factors in human happiness or misery. As to the causes of pleasure, the means by which it was to be attained, these are in themselves indifferent; an action which gives pleasure is good, whether or not it be opposed to the religion or laws of the country. The predicates, good and bad, attached to actions independently of their consequences, are merely conventional, and not founded in nature. Yet Aristippus was compelled to admit that some actions which give immediate pleasure entail more than their equivalent of pain. This fact, he thought, was the true ground of the conventional distinction of right and wrong, and in this sense regard ought to be had to custom and law. But there is quite another side of the Cyrenaic doctrine, which appears as strongly in the theory as in the practice of Aristippus. Man must not give up himself as a slave to pleasure; he must be superior to it. True happiness can only be obtained by rational insight, prudence (φρόνησις), or wisdom. Only through this prudence, which is in truth virtue, can man make a proper use of the good things in his power, and free himself from those superstitions and violent passions that stand in the way of happiness. Through this wisdom we are enabled to preserve the mastery of pleasure, to rise superior to past, future, or even present happiness, and make ourselves independent of circumstances. True freedom of soul, real self-sufficiency, is given by wisdom, by mental cultivation. It is evident that at this point Aristippus approximates more closely to Socrates and the Cynics; and it is a suggestive fact that his followers, who pushed his principles to their logical consequences, landed in a theory of the negation of pleasure, nearly identical with the later Cynic views.

(Wendt, *De Phil. Cyrenaica*, 1841; H. v. Stein, *De Phil. Cyren.*, pt. i., "De Vita Aris.," 1855; Mullach, *Frag. Phil. Græc.*, ii. 397–438.)

ARISTO, or ARISTON, of Chios, a Stoic philosopher and pupil of Zeno, flourished about 250 B.C. He differed from Zeno on many points, and approximated more closely to the Cynic school. He was very eloquent (and was therefore sometimes called the Siren), but was controversial in tone. He despised logic as useless, and rejected the philosophy of nature as beyond the powers of man. Ethics alone he considered worthy of study, and in that only general and theoretical questions. He rejected altogether Zeno's doctrine of things desirable and intermediate between virtue and vice. According to him, there is no medium; everything that is not virtuous (*e.g.*, external conditions, fortune, health), is absolutely indifferent. There is only one virtue—a clear, intelligent, healthy disposition of mind. Aristo is frequently confounded with another philosopher of the same name, Ariston of Julis, in Ceos, who, about 230 B.C., succeeded Lyco as scholarch of the Peripatetics. He appears to have been a man of no weight or originality of mind.

ARISTOBULUS of CASSANDRIA, one of the generals who accompanied Alexander the Great, and who afterwards, when very aged, wrote a history of the expedition. This work was much used by Arrian, who praises it highly. Only a few fragments remain; these are given in Müller's *Hist. Græc. Frag.*

ARISTOBULUS, a Jew of Alexandria, and a philosopher of the peripatetic school, flourished about 160 B.C., in the reign of Ptolemy Philometer. He is the first representative of the Jewish-Alexandrian philosophy, the aim of which was to reconcile and identify Greek philosophical conceptions with the Jewish religion. Only a few fragments of his work, entitled *Commentaries on the Writings of Moses*, are quoted by Clement, Eusebius, and other theological writers, but they suffice to show its object. He endeavoured to prove that early Greek philosophers had borrowed largely from some parts of Scripture which had become known to them; in support of this view, he quoted from Linus, Orpheus, Musæus, and others, passages which strongly resemble the Mosaic writings. These passages, however, were mere forgeries, and it is surprising that any of the Alexandrian scholars should have been deceived by them.

ARISTOPHANES. The birth-year of Aristophanes is uncertain. He is known to have been about the same age as Eupolis, and is said to have been "almost a boy" (σχεδὸν μειρακίσκος) when his first comedy was brought out in 427 B.C. The most probable conjecture places his birth in or about the year 448 B.C. His father Philippus was a landowner in Ægina. Aristophanes was an Athenian citizen of the tribe Pandionis, and the deme Cydathenê. The stories which made him a native of Cameirus in Rhodes, or of the Egyptian Naucratis, had probably no other foundation than an indictment for usurpation of civic rights (ξενίας γραφή) which appears to have been more than once laid against him by Cleon. His three sons—Philippus, Arârôs, and Nicostratus—were all comic poets. Philippus, the eldest, was a rival of Eubulus, who began to exhibit in 376 B.C. Arârôs brought out two of his father's latest comedies,—the Côcalus and the Æolosicôn, and in 375 began to exhibit works of his own. Nicostratus, the youngest, is assigned by Athenæus to the Middle Comedy, but belongs, as is shown by some of the names and characters of his pieces, to the New Comedy also.

Plato's *Symposium*—in which Aristophanes has a place at the side of Socrates—shows that Plato bore no more ill-will than his master would have borne to the author of the *Clouds*. At the end of that banquet, "Aristodêmus said that Eryximachus, Phædrus, and others went away; he himself fell asleep, and as the nights were long, took a good rest; he was awakened towards daybreak by a crowing of cocks, and when he awoke, the others were either asleep or had gone away; there remained awake only Aristophanes, Socrates, and Agathon, who were drinking out of a large goblet which they passed round, and Socrates was discoursing to them. Aristodêmus did not hear the beginning of the discourse, and he was only half awake; but the chief thing which he remembered was Socrates insisting to the other two that the genius of comedy was the same as that of tragedy, and that the writer of tragedy ought to be a writer of comedy also. To this they were compelled to assent, being sleepy, and not quite understanding his meaning. And first of all Aristophanes fell asleep; and then, when the day was already dawning, Agathon."

Although tragedy and comedy had their common origin in the festivals of Dionysus, the regular establishment of tragedy at Athens preceded by half a century that of comedy. The Old Comedy may be said to have lasted about 80 years (470–390 B.C.), and to have flourished about 56 (460–404 B.C.) Of the forty poets who are named as having illustrated it the chief were Cratinus, Eupolis. and Aristophanes. The Middle Comedy covers a period of about 70 years (390-320 B.C.), its chief poets being Antiphanes, Alexis, Plato Comicus, Theopompus, and Strattis. The New Comedy was in vigour for about 70 years (320-250 B.C.), having for its foremost representatives Menander Philemon, and Diphilus. The Old Comedy was possible only for a thorough democracy. Its essence was a satirical censorship, unsparing in personalities, of public and of private life—of morality, of statesmanship, of education, of literature, of social usage—in a word, of everything which had an interest for the city or which could amuse the citizens. Preserving all the freedom of banter and of riotous fun to which its origin gave it an historical right, it aimed at associating with this a strong practical purpose—the expression of a democratic public opinion in such a form that no misconduct or folly could altogether disregard it. That licentiousness, that grossness of allusion which too often disfigures it, was, it should be remembered, exacted by the sentiment of the Dionysiac festivals, as much as a decorous cheerfulness is expected at the holiday times of other worships. This was the popular element. Without this the entertainment would have been found flat and unseasonable. But for a comic poet of the higher calibre the consciousness of a recognised power which he could exert, and the desire to use this power for the good of the city, must always have been the uppermost feelings. At Athens the poet of the Old Comedy had an influence analogous, perhaps, rather to that of the journalist than to that of the modern dramatist. But the established type of Dionysiac Comedy gave him an instrument such as no public satirist has ever wielded. When Molière wished to brand hypocrisy he could only make his Tartuffe the central figure of a regular drama, developed by a regular process to a just catastrophe. He had no choice between touching too lightly, and using sustained force to make a profound impression. The Athenian dramatist of the Old Comedy worked under no such limitations of form. The wildest flights of extravagance were permitted to him. Nothing bound him to a dangerous emphasis or a wearisome insistence. He could deal the keenest thrust, or make the most earnest appeal, and at the next moment—if his instinct told him that it was time to change the subject—vary the serious strain by burlesque. He had, in short, an incomparable scope for trenchant satire directed by sure tact.

Aristophanes is for us the representative of the Old Comedy. But it is important to notice that his genius, while it includes, also transcends the genius of the Old Comedy. He can denounce the frauds of a Cleon, he can vindicate the duty of Athens to herself and to her allies, with a stinging scorn and a force of patriotic indignation which make the poet almost forgotten in the citizen. He can banter Euripides with an ingenuity of light mockery which makes it seem for the time as if the leading Aristophanic trait was the art of seeing all things from their prosaic side. Yet it is neither in the denunciation nor in the mockery that he is most individual. His truest and highest faculty is revealed by those wonderful bits of lyric writing in which he soars above everything that can move laughter or tears, and makes the clear air thrill with the notes of a song as free, as musical, and as wild as that of the nightingale invoked by his own chorus in the *Birds*. The speech of Dikaios Logos in the *Clouds*, the praises of country life in the *Peace*, the serenade in the *Ecclesiazusæ*, the songs of the Spartan and Athenian maidens in the *Lysistrata*, above all, perhaps, the chorus in the *Frogs*, the beautiful chant of the Initiated,—these passages, and such as these, are the true glories of Aristophanes. They are the strains, not of an artist, but of one who warbles for pure gladness of heart in some place made bright by the presence of a god. Nothing else in Greek poetry has quite this wild sweetness of the woods. Of modern poets Shakespeare alone, perhaps, has it in combination with a like richness and fertility of fancy.

Fifty-four comedies were ascribed to Aristophanes. Forty-three of these are allowed as genuine by Bergk. Eleven only are extant. These eleven form a running commentary on the outer and the inner life of Athens during 36 years. We will notice them briefly in the order of their dates. They may be ranged under three periods. The first of these periods, extending to 420 B.C., includes those plays in which Aristophanes uses an absolutely unrestrained freedom of political satire. The second period ends with the year 405. Its productions are distinguished from those of the earlier time by a certain degree of reticence and caution. The third period, down to 388 B.C., comprises two plays in which the transition to the character of the Middle Comedy is well marked, not merely by disuse of the parabasis, but by general self-restraint.

I. *First Period.*

(1.) 425 B.C. *The Acharnians.*—Since the defeat in Bœotia the peace party at Athens had gained ground, and in this play Aristophanes seeks to strengthen their hands. Dicæopolis, an honest countryman, is determined to make peace with Sparta on his own account, not deterred by the angry men of Acharnæ, who crave vengeance for the devastation of their vineyards. He sends to Sparta for samples of peace; and he is so much pleased with the flavour of the Thirty Years' sample that he at once concludes a treaty for himself and his family. All the blessings of life descend on him; while Lamachus, the leader of the war party, is smarting from cold, snow, and wounds.

(2.) 424 B.C. *The Knights.*—Three years before, in his *Babylonians*, Aristophanes had assailed Cleon as the typical demagogue. In this play he continues the attack. The Dêmos, or State, is represented by an old man who has put himself and his household into the hands of a rascally Paphlagonian steward. Nicias and Demosthenes, slaves of Dêmos, contrive that the Paphlagonian shall be supplanted in their master's favour by a sausage-seller. No sooner has Dêmos been thus rescued than his youthfulness and his good sense return together.

(3.) 423 B.C. *The Clouds* (the first edition; a second edition was brought out in 422 B.C.)—This play would be correctly described as an attack on the new spirit of intellectual inquiry and culture rather than on a school or class. Two classes of thinkers or teachers are, however, specially satirised under the general name of "Sophist" (v. 331)—1. The Physical Philosophers—indicated by allusions to the doctrines of Anaxagoras, Hêracleitus, and Diogenes of Apollônia. 2. The professed teachers of rhetoric, belles lettres, &c., such as Protagoras and Prodicus. Socrates is taken as the type of the entire tendency. A youth named Pheidippides—obviously meant for Alcibiades—is sent by his father to Socrates to be cured of his dissolute propensities. Under the discipline of Socrates the youth becomes accomplished in dishonesty and impiety. The conclusion of the play shows the indignant father preparing to burn up the philosopher and his hall of contemplation.

(4.) 422 B.C. *The Wasps.*—This comedy, which suggested *Les Plaideurs* to Racine, is a satire on the Athenian love of litigation. The strength of demagogy, while it lay chiefly in the ecclêsia, lay partly also in the paid dicasteries. From this point of view the *Wasps* may be regarded as supplementing the *Knights.* Philocleon (admirer of Cleon), an old man, has a passion for lawsuits,—a passion which his son, Bdelucleon (detester of Cleon) fails to check, until he hits upon the device of turning the house into a law-court, and paying his father for absence from the public suits. The house-dog steals a Sicilian cheese; the old man is enabled to gratify his taste by trying the case, and, by an oversight, acquits the defendant. In the second half of the play a change comes over the dream of Philocleon; from litigation he turns to literature and music, and is congratulated by the chorus on his happy conversion.

(5.) 421 B.C. (Curtius, *Hist. of Greece*, vol. iii. p. 275, transl. Ward.) *The Peace.*—In its advocacy of peace with Sparta, this play, acted at the Great Dionysia shortly before the conclusion of the treaty, continues the purpose of the *Acharnians*. Trygæus, a distressed Athenian, soars to the sky on a beetle's back. There he finds the gods engaged in pounding the Greek States in a mortar. In order to stop this, he frees the goddess Peace from a well in which she is imprisoned. The pestle and mortar are laid aside by the gods and Trygæus marries one of the handmaids of Peace.

II. *Second Period.*

(6.) 414 B.C. *The Birds.*—Peisthetærus, an enterprising Athenian, and his friend Euelpides persuade the birds to build a city—"Cloud-Cuckoo-borough"—in mid air, so as to cut off the gods from men. The plan succeeds; the gods send envoys to treat with the birds; and Peisthetærus marries Basileia, daughter of Zeus. Some have found in the *Birds* a complete historical allegory of the Sicilian expedition; others, a general satire on the prevalence at Athens of headstrong caprice over law and order; others, merely an aspiration towards a new and purified Athens—a dream to which the poet had turned from his hope for a revival of the Athens of the past. In another view, the piece is mainly a protest against the religious fanaticism which the incident of the Hermæ had called forth. It can hardly be doubted that both this fanaticism and the part taken by Alcibiades in promoting the Sicilian expedition were present to the mind of Aristophanes; but in what proportions, and tempered with what other elements, the very form of the comedy makes it idle to inquire.

(7.) 411 B.C. *The Lysistrata.*—This play was brought out during the earlier stages of those intrigues which led to the Revolution of the Four Hundred. It appeared shortly before Peisander had arrived in Athens from the camp at Samos for the purpose of organising the oligarchic policy. The *Lysistrata* expresses the popular desire for peace at any cost. As the men can do nothing, the women take the question into their own hands, occupy the citadel, and bring the citizens to surrender.

(8.) 411 B.C. *The Thesmophoriazusæ.*—This came out three months later than the *Lysistrata*, during the reign of terror established by the oligarchic conspirators, but before their blow had been struck. The political meaning of the play lies in the absence of political allusion. Fear silences even comedy. Only women and Euripides are satirised. Euripides is accused and condemned at the female festival of the Thesmophoria.

(9.) 405 B.C. *The Frogs.*—This piece was brought out just when Athens had made her last effort in the Peloponnesian war, eight months before the battle of Ægospotami, and about fifteen months before the taking of Athens by Lysander. It may be considered as an attempt to distract men's minds from public affairs. It is a literary criticism. Æschylus and Euripides were both lately dead. Athens is beggared of poets; and Dionysus goes down to Hades to bring back a poet. Æschylus and Euripides contend in the under-world for the throne of tragedy; and the victory is at last awarded to Æschylus.

III. *Third Period.*

(10.) 393 B.C. *The Ecclesiazusæ.*—The women, disguised as men, steal into the ecclesia, and succeed in decreeing a new constitution. At this time the demagogue Agyrrhius led the assembly; and the play is, in fact a satire on the general demoralisation of public life.

(11.) 388 B.C. *The Plutus.*—The first edition of the play had appeared in 408 B.C., being a symbolical representation of the fact that the victories won by Alcibiades in the Hellespont had brought back the god of wealth to the treasure-chamber of the Parthenon. In its extant form the *Plutus* is simply a moral allegory. Chremylus, a worthy but poor man, falls in with a blind and aged wanderer, who proves to be the god of wealth. Asclêpius restores eyesight to Plutus; whereupon all the just are made rich, and all the unjust are reduced to poverty.

Among the lost plays, the following are the chief of which anything is known:—

1. *The Banqueters* (Δαιταλεῖς), 427 B.C. — A satire on young Athens. A father has two sons; one is brought up in the good old school, another in the tricky subtleties of the new; and the contrast of results is the chief theme.

2. *The Babylonians*, 426 B.C.—Under this name the subject-allies of Athens are represented as "Babylonians" —barbarian slaves, employed to grind in the mill. The oppression of the allies by the demagogues—a topic often touched elsewhere—was, then, the main subject of the piece, in which Aristophanes is said to have attacked especially the system of appointing to offices by lot. The comedy is memorable as opening that Aristophanic war upon Cleon which was continued in the *Knights* and the *Wasps*.

The Merchantmen, *The Farmers*, *The Preliminary Contest* (*Proagôn*), and possibly the *Old Age* (*Gêras*), belonged to the First Period. The *Gêras* is assigned by Süvern to 422 B.C., and is supposed to have been a picture of dotage similar to that in the *Knights*. A comedy called *The Islands* is conjectured to have dealt with the sufferings imposed by the war on the insular tributaries. The *Triphales* was probably a satire on Alcibiades; the *Storks*, on the tragic poet Patrocles.

In the *Æolosicôn*—produced by his son Arârôs in 387 B.C.—Aristophanes probably parodied the *Æolus* of Euripides. The *Côcalus* is thought to have been a parody of the legend, according to which a Sicilian king of that name slew Minôs.

A sympathetic reader of Aristophanes can hardly fail to perceive that, while his political and intellectual tendencies are well marked, his opinions, in so far as they colour his comedies, are too indefinite to reward, or indeed to tolerate, analysis. Aristophanes was a natural conservative. His ideal was the Athens of the Persian wars. He disapproved the policy which had made Athenian empire irksome to the allies and formidable to Greece; he detested the vulgarity and the violence of mob-rule; he clave to the old worship of the gods; he regarded the new ideas of education as a tissue of imposture and impiety. How far he was from clearness or precision of view in regard to the intellectual revolution which was going forward, appears from the *Clouds*, in which thinkers and literary workers who had absolutely nothing in common are treated with sweeping ridicule as prophets of a common heresy. Aristophanes is one of the men for whom opinion is mainly a matter of feeling, not of reason. His imaginative susceptibility gave him a warm and loyal love for the traditional glories of Athens, however dim the past to which they belonged; a horror of what was ugly or ignoble in the present; a keen perception of what was offensive or absurd in pretension. The broad preferences and dislikes thus generated were enough not only to point the moral of comedy, but to make him, in many cases, a really useful censor for the city. The service which he could render in this way was, however, only negative. He could hardly be, in any positive sense, a political or a moral teacher for Athens. His rooted antipathy to intellectual progress, while it affords easy and wide scope for his wit, must, after all, lower his intellectual rank. The great minds are not the enemies of ideas. But as a mocker—to use the word which seems most closely to describe him on this side—he is incomparable for the union of subtlety with riot of the comic imagination. As a poet, he is immortal. And, among Athenian poets, he has it for his distinctive characteristic that he is inspired less by that Greek genius which never allows fancy to escape from the control of defining, though spiritualising, reason, than by such ethereal rapture of the unfettered fancy as lifts Shakespeare or Shelley above it,—

> "Pouring his full heart
> In profuse strains of unpremeditated art."

Best recent editions, &c.—(1.) *Text.*—Bergk, 2 vols., Teubner, 1867; Holden (expurgated edition), Bell, 1868. (2.) *Commentaries.*—Acharnenses, Equites, Nubes, Vespæ, W. C. Green, in the *Catena Classicorum*, Rivingtons, 1870; Nubes and Ranæ, A. Sidgwick (for beginners), Rivingtons, 1872. (3.) *Translations.*—Mitchell (Acharn., Knights, Clouds, Wasps), 2 vols., 1822; J. H. Frere (Acharn., Knights, Birds, Frogs, Peace) being 2d vol. of his works, Pickering, 1871; B. H Kennedy, The Birds (with an excellent introduction), Macmillan, 1874. (R. C. J.)

ARISTOPHANES of BYZANTIUM, one of the most famous of the Alexandrian critics, flourished about the middle of the 3d century B.C. He studied under Eratosthenes and Zenodotus, and himself founded a school for grammar and criticism, of which the most distinguished pupil was the great Aristarchus of Samothrace. He was afterwards appointed to the superintendence of the Alexandrian library. Aristophanes, like his great pupil, was celebrated as an Homeric critic, but little is known of the results of his labours on that poet. He seems, however, to have been particularly occupied with the consideration of questions of authenticity. He arranged and commented on the works of Hesiod, Alcæus, Pindar, Anacreon, Callimachus, Plato, and Aristotle; he also explained and wrote arguments to the plays of Aristophanes and the tragic poets. He is justly celebrated as the inventor of the Greek system of punctuation, accent, and breathing. To him, also, is due in great measure the foundation of the well-known Alexandrian Canon.

The fragments of his works have been collected and published by A. Nauck, *Aristophanis Byzantii Fragmenta*, 1848. See also, Kreuser, *Griech. Accentlehre*; Villoisson, *Proleg ad. Hom. Il.*; F A. Wolf, *Proleg. in Hom*

ARISTOTLE

IN the history of European thought and knowledge, down to the period of the revival of letters, the name of Aristotle was, without a rival, supreme; and this supremacy arose from no false estimate or unwarranted preference. Aristotle, speaking generally, treated of every subject which came within the range of ancient thought, and if we regard matter, and not form or literary style, he treated of each of these subjects better than any one else. He also initiated many new branches of inquiry, dependent on observation and induction, and thus not only represented in himself the culmination of Greek speculative philosophy, but was also, as far as possible, the forerunner of modern science. Therefore, the sense of mankind recognised him gradually (after many vicissitudes of appreciation) as the strongest of the ancients. It even came to pass that, for a long period, all secular writings but those of Aristotle had dropped out of notice in Europe. His works may almost have the credit of having saved men from relapsing into barbarism. All sought in Aristotle the basis of knowledge. Universities and grammar schools were founded in Aristotle. Dante only justly expresses this predominance, when he speaks of Aristotle[1] as "the master of those that know," and depicts him as centre and head of the philosophic family. Of the influence which he has exercised over the minds of men we have evidence, not only in the vast literatures connected with his system, which exist in all great libraries, but also in the traces which that system has left in all the modern languages of Europe. The number of Aristotelian "fossils"[2] existing in our everyday language is quite remarkable. If it had not been for the system of Aristotle, we should have had to express many of our ordinary thoughts differently

The thought of Aristotle takes its start out of two separate sets of elements previously existing in Greece: the one purely philosophical, the other scientific. In Plato were summed up and remoulded all the former results of logical, metaphysical, psychological, ethical, and political speculation in Greece. And Aristotle was, in the first place, thoroughly imbued with Plato, and all the purely philosophical side of his writings was conceived in close relation to Plato's works, the results of which he may be said to have codified, reducing into expository form what Plato had left scattered up and down, rather as hints and suggestions, in his brilliant dramatic dialogues. Partly, then, Aristotle adopted the results of Plato, and made them available for the world in general; partly he dissented from some of the Platonic doctrines, and carried on a polemic against them. To compare the Platonic dialogues with the works of Aristotle, and to trace the agreements and disagreements between them, forms an interesting study in the history of philosophy. But on the whole, the difference between Aristotle and Plato is one of aims rather than of doctrines. Aristotle's aim, almost from first to last, is to be scientific, and to reduce even philosophy to science. He wishes to deal with what can be known for certain, and to express this in exact language. Plato's aim was, in one sense, greater than this; in another sense it was inferior to it. Plato stood apart from dogmatic systematising; he seems to have regarded truth as too great and many-sided to be capable of being submitted to such a process; he was content to develop various aspects of the truth, on all the highest questions, as they appeared to different minds, or to the same mind at different periods. To do this he chose the vehicle of the dramatic dialogue, in which nothing was positively announced beyond the views arrived at for the moment by the particular speakers. He was a poet at the same time

[1] *Inferno*, canto iv 130, *sqq.*

[2] The Aristotelian words in modern use come chiefly through Latin renderings of his phraseology. Some of them are.—*Maxim* = a major premiss; *principle*, from *principium*, the translation of Aristotle's ἀρχή, has the same meaning. *Subject* (τὸ ὑποκειμένον) comes from the doctrine of the four causes. So does *matter* from *materies* (timber), the Latin for ὕλη. So *form*, *end*, *final cause*, &c. *Motive* is a fossilised confusion, as it should stand for the efficient cause (ἀρχὴ κινήσεως), whereas it really denotes the final cause of action. *Faculty* (in Universities) represents Aristotle's δύναμις = art. *Energy* is of purely Aristotelian origin, though not quite keeping its philosophic sense. *Actually* is from the Latinised form of the same term. So, too, in *category* and *predicament* (*e.g.*, "an unpleasant predicament") we preserve both the Greek and Latin form of an Aristotelian term. *Habit* (in morals) varies a little in meaning from ἕξις. We have also another *habit* (*i.e.*, "dress") from ἔχειν (see note 2, p 515). The *mean* and the *extremes* still live in modern parlance, and so does the *quintessence*, or fifth substance beyond the four elements of which the outer heaven, according to Aristotle, was composed. *Metaphysics* is derived from the name given by his followers to his last treatise, and *natural history* from his "*Histories*," or investigations "about animals."

that he was a philosopher, and his works exhibit that true note of poetry which consists in constant attention to form, so that no part is a mere means to a final result; but each part is treated as an end in itself, and contains its own beauty and perfection. His dialogues are thus masterpieces of consummate literary art, though somewhat indefinite in their conclusions, and not without a tinge of imaginative mysticism. To all these Platonic tendencies in the treatment of philosophy Aristotle was totally opposed. He disregarded form in all his extant works; he thought of matter alone, and his main care was to be definite and exhaustive. In adopting results from Plato he first stripped them of the poetry with which they had been surrounded. We shall revert below to some of the points on which he controverts Plato, but the real contrast between them is in their attitude; the one is essentially a dialectician, though of the highest and noblest type, the other more and more tends to be a man of science. Following out his proper bent, Aristotle, in many of his works, strikes on a path in which Plato had not been his precursor. In these works he lays the foundation for the sciences of Natural Philosophy, Mechanics, Physiology, and Natural History. In these branches of thought he stands related, not to Plato, but to the early Greek writers on physical subjects, the inquirers on special questions, the medical writers, and the travellers, whose works he often mentions,[1] though they are all now lost. If we possessed them, we should probably only see how meagre had been these beginnings of science, and what great things Aristotle achieved in the accumulation and systematising of knowledge, and in preparing the way for its future development.

Aristotle's complete neglect of artistic form (in his extant works), and his adherence "to essential naked truth," induced Wilhelm von Humboldt[2] to say that Aristotle was un-Greek in the character of his mind; that he was deeper and more earnest than the Greeks, but was wanting in Greek fancy and grace, and spiritual freedom of treatment. This may be so; but in point of descent Aristotle was purely Hellenic.[3] His family, however, had been settled for some generations on the Macedonian frontier, and it was there that Aristotle was born, at the town of Stageira,[4] a Greek colony, on the Strymonic gulf. This place was not far from Pella, the residence of the Macedonian king, Amyntas, whose physician Nicomachus, the father of Aristotle, became. Intercourse with the Macedonians may have, to some extent, influenced the manners of this family. But it is to be remembered that they belonged to the race of the Asclepiads, or supposed descendants of Æsculapius, and it is more natural to attribute the scientific tendencies of Aristotle's mind to the inherited character and traditions of this race than to any influence which he can have received from the Macedonians. Among those traditions it is said[5] to have been one, that "from father to son they learned the art of dissection, as regularly as others learn to read and write." The best biography of Aristotle, hitherto written, is that given by Grote in his posthumous work referred to in note 3. The chief ancient authority on the subject is Diogenes Laertius, a compiler[6] and anecdote-monger, perhaps of the 3d or 4th century A.D. His life of Aristotle contains, amid many worthless, gossiping statements, two fragments of antiquity which are of the greatest value. One of these is an extract from the chronology (χρονικά) of Apollodorus (140 B.C.), giving the dates of the chief events of Aristotle's career; the other is a catalogue of "the books which he left behind him," to the number of 146. The following are the statements of Apollodorus:—That Aristotle was born 384 B.C. That he joined Plato and passed twenty years with him, thirteen of them consecutively, and that he came to Mitylene 345 B.C. That in the first year after the death of Plato he went to Hermeas, and abode with him three years; that he came to Philip 343 B.C., when Alexander was fifteen years old; that he came to Athens 335 B.C. That he held a school in the Lyceum thirteen years, and then went to Chalcis 322 B.C., where he died of a disease, about sixty-three years old. This skeleton of the life of Aristotle is probably authentic;[7] and if so, we know as much about him as could possibly be expected. It is easy to fill up, to some extent, the details: he must have been in his seventeenth year when he came to Athens to put himself under Plato; twenty years afterwards, when Plato died, he was, on account of his great divergencies of mind from Plato, not appointed head of the school, and he, therefore, retreated to the court of his philosophical friend, Hermeas, ruler of Atarneas, in Asia Minor; he married the niece of Hermeas, who was a eunuch, and had been a slave. On his death Aristotle went to live in retirement in Mitylene, whence, in his forty-second year, he was summoned by Philip of Macedon to undertake the tuition of Alexander the Great, then fifteen years old. Seven years later Philip was assassinated and Alexander became king of Macedonia, and was immediately absorbed in plans for the conquest of the East. Aristotle now came to Athens and spent the last thirteen years of his life there, and it is these years which have the most interest for us, for in them, in all probability, he composed all those of his works[8] which still remain. In rivalry to the Platonic school which had been established in the gardens of the "Academia" on the west side of Athens, he set up his own school in the covered "walks" (περίπατοι) round the temple of the Lycean Apollo, on the east side of the city, and from this circumstance his philosophy got the appellation of "Peripatetic." His mind and the general features of his system were now mature; he had before him the task, on the one hand, of reducing to writing for the world the results of his reflections in philosophy, on the other hand, of accumulating fresh materials for those sciences of observation of which he was laying the foundation. He set himself simultaneously to writing and to teaching, and there is reason to believe that he employed

[1] See Bonitz's Index to *Aristotle*, in the 5th vol. of the edition of the Prussian Royal Academy (Berlin, 1870), under the words φυσικός, φυσιολόγος, Philosophus Incertus, περίοδοι (books of travels), ἱστορία, Ἱπποκράτης, &c., where the references to passages are given.

[2] In a letter to F. A. Wolf, dated 15th June 1795. See his works, v. 125.

[3] See *Aristotle*, by George Grote, &c. (1872), vol. i. p. 3, note.

[4] Hence his frequent appellation by the Greek commentators of ὁ Σταγειρίτης. This in English is often mis-spelt as "Stagyrite."

[5] Galen, *De Anatomicis Administr.*, ii. 1. It is a doubtful and interesting question whether Aristotle ever dissected the human subject. This would have been much opposed to Greek prejudices. See *Aristotle: a Chapter from the History of Science*, &c., by George Henry Lewes (London, 1864), pp. 159–170. We know that the school of Galen contented themselves with dissecting the lower animals; the same may generally have been the case with Aristotle. But he appears to have dissected the human fœtus, and in one place, at all events, he seems to indicate acquaintance with dissections of the adult human subject (*De Part. Animal*, i. v. 7). But his knowledge of anatomy, as compared with that of modern times, was superficial.

[6] See his *Lives of the Philosophers*, v. i.

[7] Niebuhr considered Apollodorus to be a trustworthy chronologist. Valentine Rosé, however, *De Aristotelis Librorum Ordine et Auctoritate Commentatio* (Berlin, 1854), pp. 112–119, thinks that the date of Aristotle's death can alone be relied on, and that all the other particulars are filled in, going backwards from this, on conjecture. Rose believes that the account of Aristotle's connection both with Plato and with Alexander is a mere fiction, and, in short, that we know nothing about the life of Aristotle. This is an extreme of scepticism.

[8] These works all seem to belong to the same epoch of the author's mind. They all presuppose a certain generally completed system of philosophy and a certain previously settled phraseology. But considerable development of particular thoughts can be traced as having occurred during the actual writing of the books.

his school to some extent, in co-operation with himself, to work out details, and to assist in a subordinate way in the construction of the great philosophical and scientific edifice which he had in view. The period of the zenith of Aristotle was coeval with the astonishing career of his pupil, Alexander. There is a tradition that Alexander[1] furnished him with funds for his physical and zoological researches. However this may have been, it appears certain that Aristotle was identified in Athens with the Macedonian cause, and that when, in the summer of 323 B.C., the startling news of the sudden death of Alexander was spread through Greece, Aristotle was involved in the temporary fall of a political party, and those who, from different causes, were his enemies, made an attack upon him which caused him to fly from Athens. Grote has well drawn out the various elements of enmity existing against Aristotle, and to his account we refer. Aristotle retired to Chalcis in Eubœa, a place garrisoned by the Macedonians, and there shortly afterwards closed, in an illness, his life of unsurpassed activity and achievement. His will, preserved by Diogenes, would seem to indicate a kind, just, and generous disposition; of the genuineness of this document we cannot be sure, but there is nothing recorded of Aristotle with any certainty which would lead us to think of him personally otherwise than with respect.[2]

After his death his works had a strange and remarkable history. His library, containing all his own autographs, many of them being MSS. of unpublished and unfinished treatises, was bequeathed to Theophrastus, his chief disciple, who, dying thirty-five years later, bequeathed them in turn, together with his own books and writings, to Neleus, a Peripatetic scholar. Neleus took the whole precious collection with him to his home at Scepsis, in Asia Minor, and his heirs concealed it in a vault to prevent its being seized by the king of Pergamus, who was then levying contributions for his royal library. The Aristotelian MSS. were thus lost to the world for 187 years. About the year 100 B.C. they were brought out of their hiding-place and sold to a wealthy book-collector, named Apellicon, who carried them back to Athens. In the year 86 B.C., on the taking of Athens by Sulla, the library of Apellicon was seized and brought to Rome. There some learned Greeks obtained access to it; Tyrannion, the friend of Cicero, arranged the MSS.; and Andronicus of Rhodes undertook the task of furnishing a correct text, and a complete edition of the philosophical works of Aristotle, out of the materials at his disposal. He arranged the different treatises and scattered fragments under their proper heads, and published what was henceforth received as the authorised edition of the works of Aristotle.[3] It seems reasonable to believe with Grote[4] that "our Aristotle," that is, the collection of writings which under this name has come down to modern times, is none other than the edition of Andronicus, and thus dates from about the year 50 B.C. For the first generation after the death of Aristotle, his scholars,[5] Theophrastus, Eudemus, Phanias, Straton, &c., were engaged partly in editing, partly in paraphrasing, sometimes in endeavouring to improve upon his mostly unfinished works. But the Peripatetic school very rapidly declined; all the philosophic ability round the shores of the Ægean threw itself into one or other of the two new rival schools which had arisen, the Stoic and the Epicurean. The Peripatetics could not keep up to their master's level; they soon lost interest in the higher parts of his system; they took to writing monographs[6] on small separate questions, and moral platitudes[7] dressed up in rhetorical form. We may hesitate to affirm that, during 187 years, there were absolutely no copies of Aristotle's greatest works extant besides those hidden in the vault of Scepsis, for the Stoical ethics and logic both bear traces of a knowledge of Aristotle. But, at all events, for the time, the world had lost its interest in all that we most prize in Aristotle's thought. Strabo[8] says expressly that "all his writings, except a few of a more popular character," had been lost; and in accordance with this, Cicero[9] says that "even philosophers know nothing of Aristotle, though they ought to have been attracted by the incredible sweetness of his diction." The latter part of this remark may seem surprising, for it is not in the least applicable to any of the works of Aristotle which have come down to us. But Cicero is evidently referring to the Dialogues,[10] which were read, admired, and attributed to Aristotle in the days before the edition of Andronicus became known. The question has been raised, especially by Valentine Rose,[11] whether these dialogues, and other short, unsystematic works which passed under the name of Aristotle, were all forgeries, or were in any case genuine. On the one hand it is urged that the dialogic, or artistic, mode of exposition, was alien from Aristotle's turn of mind. On the other hand, it may be said that Aristotle in his youth may very probably have tried his hand at imitating the Platonic dialogues. And, indeed, unless he had done so, it is difficult to understand how even the forgers could have ventured to publish dialogues bearing his name. Very likely, after his death and the loss of the main bulk of his works by their removal to a vault in Asia Minor, a crop of forged Aristotelian writings sprung up, and imitations of his earlier and more popular works were among the number. But still, it appears safest to believe that Aristotle did at one time endeavour to make the dialogue his vehicle for philosophy. In the years that followed the death of Plato, he probably felt within himself a reaction and repugnance against this mode of writing, and when he returned to Athens as the leader of a school, he utterly renounced it, and set himself henceforth to the statement of the naked truth in the directest and most scientific terms which he could find. Whether the dialogues which Cicero and his contemporaries read and admired were early works of Aristotle himself, or were forgeries, there is no means of knowing. But the fragments[12] of these works, which a search of all ancient literature has brought together, show us nothing worthy of Aristotle in his best days, nothing that contributes any light to his philosophy. And it is remarkable that all works of this kind seem to have been excluded from the edition of Andronicus. Owing to that exclusion they are all now lost, and thus the tables are turned, for whereas before the edition of Andronicus the

[2] See some remarks in the *Edinburgh Review*, No. 278, page 525.

[3] The authorities for this story are Strabo (who was the pupil of Tyrannion), xiii. 609; Plutarch, *Sulla*, c. xxvi.; Porphyry, *Vita Plotini*, p. 117. It has been much criticised by Stahr, Brandis, Zeller, Bernays, Rose, &c. For the last remarks on the subject see Grote (*l. c.*), and Sir A. Grant's *Ethics of Aristotle, illustrated with Essays and Notes, 2d edition* (London, 1874), essay i. pp. 5–18.

[4] *Aristotle*, vol. i. pp. 57–62.

[5] See Brandis, *Scholia in Arist.*, p. 28, note.

[6] See Rose, *Aristoteles Pseudepigraphus* (Leipsic, 1863), pp. 20–22, where a list of many such productions falsely ascribed to Aristotle is given.

[7] Strabo, xiii. 609, says that all they did was θέσεις ληκυθίζειν.

[8] *Ibidem.*

[9] *Topica*, i. 1–3.

[10] See Cicero, *Epist. ad Famil.*, t. ix. 23, where he speaks of his three books *De Oratore* as "a dialogue in the style of Aristotle," and *Epist. ad Atticum*, xiii. xix., where he says that he has copied Aristotle "who in his dialogues always assigns to himself the leading part in the conversation." This shows that the dialogues of Aristotle were very different from those of Plato, and were probably expository and dogmatic, and not at all dramatic.

[11] *Arist. Pseudepigraphus*, pp. 23–26.

[12] These fragments are given collectively in the 5th volume of the Prussian Royal Academy's edition of Aristotle (Berlin, 1870).

world had forgotten all about Aristotle, except so far as he was represented by his own youthful and lighter productions, or by spurious imitations of these, it came to pass later that all except his solid and great philosophical treatises passed into oblivion.

Turning now to the catalogue of the works of Aristotle which has been preserved by Diogenes Laertius, we find that it contains 146 different names, not one of which[1] seems to correspond with any of the forty works which make up "our Aristotle." This is very striking, and suggests the question, Did Aristotle really write all these works enumerated in the catalogue, and if so, how is it that they are all lost? Did he really write over and over again on the same subject, as the catalogue, taken together with our edition, would indicate? Or is the catalogue virtually a list of forgeries, published under the name of Aristotle at the time when the unique MSS. of many of his greatest works were shut up underground and forgotten? Neither hypothesis can be accepted absolutely, but the last mentioned contains, probably, by far the nearest approximation to the truth. It seems credible that the catalogue in question was taken from the backs of rolls in the Alexandrian library, and that it was made by Hermippus, pupil of Callimachus, the chief librarian, between the years 240 and 210 B.C.[2] It found its way into some biography, and was thence mechanically copied by Diogenes. If this be so, it represents the kind of books which were being received by the world as Aristotle's at a time when the real Aristotle was buried out of sight. The books enumerated in the catalogue strike us at once as peculiar in character: first we meet with the names of several dialogues (such as "Nerinthus," "Gryllus, or on Rhetoric," "Menexenus," "Symposium," "the Lover," &c.); afterwards there are the names of apparently short treatises or monographs on separate subjects;[3] without any trace of that organic unity of each of the great branches of philosophy which we find in Aristotle as we know him. This organic unity has not been superinduced by the editorial labours of Andronicus, for we see by the openings of the *Metaphysics*, *Ethics*, *Politics*, and other existing works, taken in connection with their succeeding parts, that Aristotle conceived a grand and comprehensive plan for each main branch of philosophy and science; that he proposed to follow this out so as to produce in each case a complete whole, but that most of his multifarious designs were arrested by death, so that much that he has left bears the character of a mighty fragment. But the Peripatetic school seem to have abandoned his comprehensive views, and to have only followed him in that other side of his method which consisted in working out the details of special and subordinate questions. This tendency resulted in the production of small separate treatises and essays, and it is the names of such as these that are recorded in the catalogue. The Peripatetic school seem to have worked on a sort of co-operative principle. Aristotle, during his own lifetime, probably encouraged them to work up separate points for incorporation into his philosophy, and if so, they would have less scruple in affixing his name to works written after his death, but which they conceived to represent, or, perhaps, a little to improve upon, his views. Whatever may have been the literary morality of this procedure, we can hardly doubt that it existed as a fact. Even the works of Aristotle, as we possess them, show clear traces of it. Take, for instance, the four different ethical treatises which are found among these works. Of these the first is the *Nicomachean Ethics*,[4] the main bulk of which is the genuine writing of Aristotle. It is conceived on a comprehensive plan, and the beginning and end are complete, but the middle part was probably never written. The name of this treatise was, perhaps, given to it for the sake of distinguishing it from the other ethical works in the Peripatetic school library, the MS. of this having been to some extent revised and edited by Nicomachus, the son of Aristotle. The second is the *Eudemian Ethics*, a paraphrase of the work of Aristotle, written by Eudemus, one of his scholars, with a slight divergence in some points from the original doctrines. Three books from the *Eudemian* treatise, on Justice, on the Relation of the Intellect to Morality, and on Weakness of the Will, were afterwards incorporated by some editor into the *Nicomachean Ethics*, so that in modern times they have always formed part of both treatises, and their authorship has been much disputed.[5] The third is called the *Great Ethics*,[6] and is the work of a later Peripatetic; it is a *résumé* of morals, made up chiefly out of the work of Eudemus, but with some of its conclusions taken directly from that of Aristotle, and with some matter introduced from another source, perhaps the ethical writings of Theophrastus. The fourth is a little tract *On Virtues and Vices*, which is not even Aristotelian in doctrine, though it shows an acquaintance with the Aristotelian system. It is chiefly characterised by some small points of physiognomical observation, such as are found in the *characters* of Theophrastus. These four works well illustrate the growth of an ungenuine Aristotelian literature. We begin with a genuine work of Aristotle himself, though even into this a spurious element has been introduced; we go on to a paraphase, and then to the paraphrase of that paraphrase, we end with a light essay written for the sake of one or two observations on character which the writer had made, and yet all stands under the name of Aristotle.[7] This instance which we have before our eyes, and the proportion of the ungenuine to the genuine which it presents, may enable us to form a conception of the nature of those works, the 146 names of which make up the catalogue of Diogenes. Far be it from us to say that none of the works so enumerated were written by Aristotle himself, but probably much the greater portion of them were not written by him. And without denying that many works of Aristotle, and even some works by him of interest and value, have been lost, we may say with confidence that the "lost works"[8] of Aristotle were of no importance in comparison with what has been preserved,

[1] With the exception of "*Categories*, in one book," and "*On Interpretation*, in one book." "*Great Posterior Analytics*, in two books," may stand to the *Post. Anal.* of Aristotle as the *Great Ethics* do to *Eth. Nicomach.* Titze, Michelet, and other writers, have endeavoured to identify some of the monographs of the catalogue with *parts* of Aristotle's extant works, *e.g.*, works *On the Voluntary*, *On Friendship*, *On Pleasure*, with parts of *Eth. Nic.*; the book *On the Various Senses of Words*, with part of the *Metaphysics*, &c. But, as Grote says, vol. i. p. 61, note, "the identification is not convincing." In fact, the theory is untenable.

[6] This name may have been due to the vanity of the compiler. We have seen in the Catalogue of Diogenes the name *Great Posterior Analytics*. See above note 1.

[7] Whether all stood thus in the edition of Andronicus, or whether some of these works were added in subsequent editions, we have no means of knowing. If the former, Andronicus must have aimed at giving a collected body of Aristotelian doctrine, rather than an edition of Aristotle's own undoubted writings. We know that Andronicus pronounced the treatise *On Interpretation* to be spurious, and yet we find it in our edition of Aristotle.

[8] See above, note 1, and compare Valentine Rose, *Arist. Pseudepigraph.*, where the fragments are commented upon.

and that the greatest and most valuable of his achievements, incomplete as he left them, but subsequently edited to some extent and touched up, remain for us, and contain the essence of his thought.

In eight passages of the works which we possess under his name, there is a reference to "exoteric discourses" (ἐξωτερικοὶ λόγοι).[1] This phrase has attracted a wonderful amount of notice, and a whole literature[2] has been composed in support of the different meanings which have been attributed to it. But the question is now reduced to a very small one. The word "exoteric" suggests the opposite term "esoteric," in the sense of secret; and the writers of the later empire,[3] who were accustomed to the idea of mystical and hierophantic teachings, as professed by the neo Pythagorean and neo-Platonic schools, took up the notion that Aristotle had two forms of doctrine: the one "esoteric," —containing his real opinions, and confined to the circle of his initiated scholars,—the other "exoteric," containing superficial truth with which the profane vulgar might be put off and satisfied. After the Renaissance the idea of a double doctrine in Aristotle was exploded, and it was acknowledged that "exoteric" in the passages above mentioned is not opposed to "esoteric" or "secret," but denotes the external, non-philosophical, non-scientific treatment of a subject, as opposed to the strictly scientific treatment of it (οἰκεῖος λόγος). The only question, then, which remained is this,—Does Aristotle, when he refers to "the exoteric discourses," mean to refer directly to his own more popular writings, or does he make general reference to popular discussions on philosophical subjects, including not only his own and other people's popular writings, but also the ordinary debates and discussions on such subjects, rife enough in Athenian society, and, of course, unscientifically conducted? Powerful supporters are to be found for either view, and Bernays[4] especially, in an elegant and learned monograph, has endeavoured to prove that each of the passages in which "the exoteric discourses" are mentioned refers especially to some one of the lost dialogues of Aristotle, the character and contents of which Bernays seeks to gather from the scanty fragments of them preserved by the ancients. It appears to us, however, that this attempt is infelicitous in its results, and that there are many reasons for thinking that Aristotle did not appeal to his own popular writings for conclusions in philosophy, but merely said, occasionally, that the popular views on some questions of philosophy were sufficiently accurate and might be accepted.

Of the works that have come down to us as Aristotle's, the following are undoubtedly genuine:—1. *Topics.* 2. *Prior Analytics.* 3. *Posterior Analytics.* 4. *On Sophistical Refutations.* 5. *Art of Rhetoric.* 6. *Nicomachean Ethics.*[5] 7. *Politics.* 8. *On the Art of Poetry.* 9. *A Physical Discourse.*[6] 10. *On the Heavens.* 11. *On Generation and Destruction.* 12. *Meteorologics.* 13. *Researches*[7] *about Animals.* 14. *On Soul.* 15. Appendices to the preceding work—(a.) *On Sense and Sensible Things.* (b.) *On Memory and Recollection.* (c.) *On Sleep and Waking.* (d.) *On Dreams and Prophesying in Sleep.* (e.) *On Longevity and Shortlivedness.* (f.) *On Youth and Old Age.* (g.) *On Life and Death.* (h.) *On Respiration.* 16. *On Parts of Animals.* 17. *On Locomotion of Animals.* 18. *On Generation of Animals.* 19. *The Metaphysics.*[8]

The following works attributed to Aristotle are almost undoubtedly spurious:—1. *On Rhetoric; addressed to Alexander.* 2. *Eudemian Ethics.* 3. *Great Ethics.* 4. *On Virtues and Vices.* 5. *Economics.* 6. *On Colours.* 7. *Physiognomics.* 8. *On Plants.* 9. *On Strange Statements.* 10. *Mechanics.* 11. *On Indivisible Lines.* 12. *On Xenophanes, Zeno, and Gorgias.* 13. *On the Universe; addressed to Alexander.* 14. *On Motion of Animals.* 15. *On Breath.* 16. *Problems.*[9]

The following two works are of doubtful genuineness:— 1. *Categories;* 2. *On Interpretation.* None, however, of the so-called works of Aristotle have been more commented on or studied than these two. They stand as the two first of the six logical treatises, or *Organon,*[10] of Aristotle, and thus had particular attention directed to them in the Middle Ages,[11] when the logical writings were solely or chiefly studied. The separate way in which these two short treatises are written, without any preface or other connection with the main body of analytic (*i.e.,* demonstrative logic), seems peculiar and unlike Aristotle. We may safely say that they were not composed at the same time as the *Analytics,* to which they have been prefixed. Either they were earlier works written before the time of Aristotle's final residence in Athens, or else they are the productions of unknown and probably later Peripatetics. There is an important difference of doctrine between the *Categories* and works known to be by Aristotle. For in the *Categories*[12] it is laid down that "the first essence" (πρώτη οὐσία) is the individual, and that the class, genius, or species, is a "second essence," that is, that it has an existence derived from and secondary to the individuals of which it is composed. In the *Metaphysics,*[13] on the other hand, we are told that the "first essences" are universals, genera, or species. The former is the doctrine of nominalism, the

[1] See Bonitz's Index, *sub voce,* for the references.

[2] All recent German commentators have touched upon the question. Most of the leading opinions upon it have been referred to by Grote, *Ar.,* vol. i. chapter 2. See also Grant's *Ethics,* vol. i. appendix B.

[4] *Die Dialoge des Aristoteles, in ihrem Verhältniss zu seinen übrigen Werken,* von Jacob Bernays (Berlin, 1863).

[5] With the exception of books v. vi. vii. See Grant's *Ethics.*

[6] The title cannot with certainty be attributed to Aristotle. In some MSS. it stands as Φυσικὴ ἀκρόασις, ἢ περὶ ἀρχῶν. Ἀκρόασις indicated a scientific, as opposed to a popular, lecture or discourse.

[7] Περὶ τὰ ζῷα ἱστορίαι. Ἱστορία means a "record of investigations." Aristotle sometimes uses the word simply in the sense of "history," but it was a mistranslation to call his work on animals *Historia Animalium.* Out of this the term "Natural History" has grown into modern usage.

[8] Τὰ μετὰ τὰ φυσικά. The name merely means "The writings which come after the Physics." It was given not by Aristotle himself, but by his posthumous editors. Out of it the name of "Metaphysics" grew for that science, which Aristotle himself called "First Philosophy," "Wisdom," or "Theology." See Bonitz, *Metaphysica* (Bonn, 1849), 2d part, pp. 3–6. The work is composite, with a spurious admixture. See below.

[9] An interesting paper by Karl Prantl (*Abhandl. der Philosoph.-philol. Klasse der K. Bayer-Akad.* 1852) discusses the thirty-eight books of "Problems" attributed to Aristotle, in which questions on all conceivable subjects are proposed and answered. Prantl shows the contradictory and often anti-Aristotelian character of many of the answers given. His conclusion is that, though Aristotle certainly set the example of starting and endeavouring to answer "problems" as a contribution to science, and though there may be a small nucleus of Aristotle's own writing here, yet the great mass of the contents of these books is the production of the Peripatetic school, after the time of Aristotle. The *Problems,* among other characteristics, exhibit strongly the materialistic tendencies of the Peripatetics.

[10] This name is said to have been given to the collective logical treatises by Andronicus, to indicate that they were not a *part* of philosophy, being neither "practical," "productive," nor "speculative," but that they contained the organ or *instrument* of philosophy, in the theory of reasoning. Aristotle himself uses the phrase about Dialectic, —οὐ μικρὸν ὄργανον πρὸς γνῶσιν, *Topics,* viii. 14, 3. See Grote, vol. i. p. 78, and Brandis, *Scholia,* p. 140, a. 47, p. 259, a. 48.

[11] During the 9th, 10th, and 11th centuries, a war was furiously waged between Peripatetics and Platonists, *i.e.,* between Nominalists and Realists. But all this time the Peripatetic library of Western Europe seems to have been restricted to Latin translations (by Boëthius) of the *Categories* and *Interpretations,* together with a Latin translation of Porphyry's *Introduction* to the *Categories.* The whole question of Nominalism and Realism was started by Porphyry's *Introduction.* See Hauréau, *Histoire de la Philosophie scolastique,* 2d. ed., i. (Paris, 1874).

[12] *Categ.,* v. 1.

[13] *Metaph.,* vi. 7, 4; 11, 18, &c.

latter that of realism. If Aristotle wrote the *Categories* long prior to the *Metaphysics* (which, if he wrote the book at all, he must have done), then we must suppose that at the outset of his independent career as a philosopher he began with an exteme reaction against the realism of Plato, and that in later life he returned from this to approximation towards Plato's views. The other hypothesis possible is, that a bias towards physical research and experiment and the collection of facts naturally led the Peripatetic school in the direction of nominalism, till at last some member of that school gave expression to this tendency by writing this little treatise called the *Categories*, derived, indeed, mainly from Aristotle's doctrines and teaching, but laying it down far more dogmatically than he would have done that the concrete individual is the unit of knowledge.[1] Considerations of style are insufficient to enable us to pronounce in favour of one hypothesis or the other. For the school of Aristotle copied, and obtained a close resemblance to, their master's style. But whether this treatise was written by Aristotle or not, it has had a great influence. It led the world not only to think that Aristotle was a decided nominalist, but also that he classified existence under ten "categories" or *summa genera*. But this doctrine would hardly have been gathered from the undoubted writings of Aristotle. In his logical researches he naturally much busied himself with the different relations which the predicate of a sentence can bear to the subject. And in the earliest of his extant works (*Topics*, i. 9), he enumerates "the classes of predications" (τὰ γένη τῶν κατηγοριῶν) as ten,[2] and gives the same list as that given in the *Categories;* but the object of this enumeration is merely logical, in order to show what must be meant by the word "same" when it is predicated of any subject. Elsewhere, Aristotle does not adhere to the number ten; he mentions[3] in one place eight, in another six, in another five, in another four, and very often three, κατηγορίαι, or modes of predication. There is no trace of his mapping out to himself the "Cosmos" under the divisions of ten or any other number of categories. In *De Anima*, i. 1, 7, he says that "it will be necessary, in discussing the soul, to define which of the categories it belongs to, and again whether it is a potentiality or an actuality." But, having said this, Aristotle does not further advert to the categories, while he obtains his whole definition of the soul by considering it as an "actuality." In fact, "Potentiality and Actuality," or "Matter, Form, and Deprivation," were the ontological "categories" of Aristotle, far rather than that logical list of ten kinds of predication, on which mediæval and modern thinkers have laid so much stress. That they have done so is perhaps mainly due to this little work called the *Categories*, which (whether it was an early production of Aristotle himself, or was the compilation of some peripatetic follower) has had undue prominence given to it in relation to Aristotle's system. It has caused Aristotle to be misunderstood, severely criticised, and sneered at. At the same time it has given an impulse to philosophers, from the Stoics[4] to Kant and J. S. Mill, to endeavour to frame an ultimate classification of all that exists or can be thought.

The treatise *On Interpretation* (*i.e.*, the expression of the thoughts in language) was pronounced spurious by Andronicus Rhodius. This we learn from some interesting discussions given by Brandis in his *Scholia* to Aristotle, p. 97. The opposite view seems to have been taken by Ammonius, Alexander of Aphrodisias, and Boethius. The arguments, however, both *pro* and *con* are inconclusive. Whether this treatise was by Aristotle or not, it contains a very full statement of the Peripatetic logic, so far as the Proposition, with its various characteristics, is concerned. It quotes the treatise *On Soul*,[5] and, therefore, was written later than Aristotle's undoubted logical works, more probably by one of his school than by himself. It is the source of much of the matter of the elementary logic of modern times, and contains many distinctions, at one time novel, but essential to clearness of thought,—on Affirmation and Negation, the Different Ways in which the Negative Particle may be used, Contrary and Contradictory Opposition, the Truth or Falsehood of Propositions, Modality of Assertion, &c. Grote's[6] account of the contents of this work has opened it for the English reader.

We now come to the undoubted works of Aristotle. These, as before said, were probably all actually written during his last thirteen years, but they must have, to a great extent, been prepared during the previous course of his life, during which he had thought out the divisions, the method, and the terminology of philosophy and science. The order of composition of these works, so far as it can be determined at all, must be determined by internal evidence. This internal evidence does not consist merely in references from one book to another (for these are not always reliable—in some cases they are almost certainly interpolated), but still more in comparison of the thought in different books, and the various degrees of maturity exhibited by the same conception occurring in different books. For instance, in the first chapter of the *Analytics* the *Topics* are referred to; therefore, either the *Topics* were written first, or else this reference is spurious. But the doctrine of the syllogism is worked out with far more precision in the *Analytics* than in the *Topics*, therefore the former hypothesis must be accepted. A similar combination of verbal and real internal evidence would seem to show[7] that the *Topics* (with the exception of the eighth book) were first written of all the extant works of Aristotle, next the *Analytics* (*Prior* and *Posterior*), next the eighth book of the *Topics*, next the *Rhetoric*, and then the *Sophistical Refutations*, and the same canon of criticism would lead us to believe that Aristotle next in order wrote the *Nicomachean Ethics*, and then (perhaps after an interval) the *Politics* and the treatise on *Poetry*. The above order of books may be considered as established with tolerable certainty. But the reasons seem rather far fetched which induce Valentine Rose[8] to lay down that Aristotle, in his 55th year, commenced a second series of writings with the *Physical Lectures*, which were followed by the works *On the Heavens*, *On Generation and Destruction*, and the *Meteorologics;* and afterwards a third series, with the *Researches about Animals*, followed by the work *On Soul*, and his other psycholo-

[1] In *De An.*, i. 1, 7, there is an apparent assertion of Nominalism τὸ δὲ ζῷον τὸ καθόλου ἤτοι οὐθέν ἐστιν ἢ ὕστερον), but Torstrik points out (Ar. *De An.*, p. 113) that Aristotle is here referring to the views of others, not stating his own.

[2] Substance, quantity, quality, relation, place, time, posture (κεῖσθαι), habit (or dress, ἔχειν), action, passion. Such a list would form a strange classification of all things in the universe. Some of these categories have an easily traceable affinity with the parts of speech, thus showing the relation between logic and grammar. But this is not their only source. As the individual man may sometimes be the subject of predication, his "dress" and "posture" were admitted among the classes of categories. *Habit*, from the Latinised form of ἔχειν, survives in modern languages, *e.g.*, to be "habited" is to be dressed, a lady's riding-"habit," *habit* (in French) = a coat.

gical and physiological writings. Granting that the work *On Soul* was written later than most of the other works of Aristotle, it seems to us safest to say that, in all probability, many of his works were simultaneously "on the stocks" up to the time of his death, and this makes their precise order difficult to assign.

We shall now proceed briefly to indicate, we cannot attempt more, the leading features of the contents of Aristotle's undoubted works, as they have come down to us. The books of the *Organon* (see note 10, p. 514) form together a connected whole. Of these the *Topics* appear to have been written first, but the sequence of thought between the books is that the *Prior Analytics* stand first, as containing the theory of the syllogism, a necessary preliminary to reasoning of all kinds; and then growing out of this root we have two divergent treatises: the *Posterior Analytics*, on demonstrative reasoning, or the logic of science; and the *Topics*, on dialectic, or the art of discussing subjects in which demonstration is impossible. For the details contained in these treatises we must refer the reader to Grote's (see note 3, p. 511) generally[1] excellent account. The matter of the *Prior Analytics* has become the common property of all modern books on logic. And scarcely anything[2] has had to be detracted from or added to what Aristotle wrote upon the syllogism. His was the proud distinction of having discovered and fully drawn out the laws under which the mind acts in deductive reasoning. That in deduction the mind proceeds from some universal proposition, and how it proceeds—these were the first things which Aristotle had to tell the world. The modern attempts to impugn these principles, and to show that the mind does not reason from universals, are a failure. They confuse inductive with deductive reasoning, and ignore both the case of a science like geometry, which is all deduction, and also the numerous cases where the mind, having unduly assumed a universal principle, rests in it afterwards and makes deductive applications of it. Granting that there is such a thing as deductive reasoning (and surely life is full of it), it is a great matter to have the laws of this so clearly ascertained, that about the process itself there can no longer be doubt, and any flaw in the process can instantly be detected. This was the service that Aristotle rendered in drawing out the laws of the syllogism. Men, of course, reasoned deductively by means of "the syllogism" before Aristotle had appropriated this name[3] to indicate the formula for deductive reasoning, and before he had discovered and stated the laws under which the mind acts in deductive reasoning. They did so, however, unconsciously and by instinct, just as men wrote and talked grammatically before any idea of a science or an art of grammar existed. In Aristotle deductive reasoning became conscious of itself. Unfortunately for his reputation, this merely preliminary part of his labours, in which the principles and rules of syllogistic inference were drawn out, occupied almost exclusively the minds of thinkers in the Middle Ages. The errors of modern Aristotelians were imputed to Aristotle, and hence arose the notion that Aristotle explained nature by means of the syllogism. Nothing could be further from the truth; Aristotle was not only one of the most inquiring and encyclopædical, but also one of the most thoroughly sensible, of all writers, and no one would have repudiated more strongly than himself the idea that the formula of the syllogism can be used to test or explain anything beyond the process of reasoning from certain premisses possessed or assumed, and he is never tired of telling us that the only means of obtaining premisses is by experience and observation of facts. While discussing the syllogism itself, he says,[4]—"This is the case in astronomy, which is based on the observation of astronomical phenomena, and it is the case with every branch of science or art. When the facts in each branch are brought together, it will be the province of the logician to set out the demonstrations in a manner clear and fit for use." It is true that Aristotle did nothing towards the logic of Induction, that is to say, towards elucidating the methods by which the mind legitimately arrives at general facts or laws of nature. This was left to be worked out by the moderns, by Galileo, and Bacon, and Whewell, and J. S. Mill. Aristotle, indeed, made a cursory attempt[5] to put the inductive process into syllogistic form, thus:—"A, B, and C draw iron; A, B, and C are (or represent) all magnets; therefore all magnets draw iron." It is clear that this syllogism does not explain the inductive process, it only records in the minor premiss a previous induction. The real question is, do A, B, and C here properly represent all magnets? To answer this, verification would be required. The syllogism, then, does not explain the inductive process, but only calls attention to what is implied in it. Leaving unattempted the question how the minor premiss in the Inductive syllogism is to be obtained, and how tested,—what Aristotle really works out is the logic of Deductive Science (in the *Post. Analytics*) and the logic of Deductive Probability (in the *Topics*). Under the former head he draws the ideal of a perfect science, and recounts the conditions necessary to its existence. Interesting discussions[6] are introduced by him on Causation, Hypotheses, Axioms, Ultimate Laws, Definition, and the Apprehension of Primary Truths. In all this there is little which might not be accepted by a man of science of the present day. The *Topics*, on the other hand, treat of a subject which possesses rather an antiquarian than a living interest, namely, the conduct and regulation of Dialectic as practised in Athenian society.

In the Middle Ages men made a business[7] of propounding, attacking, and defending theses, but this was a lame imitation of the spontaneous disputations of lively Athens, and from its utter profitlessness has long fallen into desuetude. The *Dialogues* of Plato may serve to give us an idea of a society possessed with an insatiate appetite for discussion and controversy, and always delighted to take part in, or assist at, an intellectual game or fencing match between two opponents. And it is the object of the *Topics* of Aristotle to lay down the rules for the game of Dialectic, and to establish it as a highly salubrious and necessary intellectual art. Dialectic, properly speaking, is discussion with a view to probable truth, and so far is worthy of the attention of a philosopher. But it may easily emerge into Eristic, which is discussion with a view to victory. Even under this aspect Aristotle does not think it ought to be neglected. Drawing on his vast and methodised observation of life, he gives rules and hints for the conduct of Eristic. The name *Topics* means "On Common-places;" the chief contents of this treatise consist of "heads" useful in arguing for or against a proposition. All this is wearisome to read in eight books. Much more readable are the *Sophistical Refutations*, which form a conclusion to the

Topics. The intellectual tendencies of Athenian society had given scope to a class, which gradually arose, of professional and paid disputants, or professors and teachers of the art of controversy. This professional class, under the name "Sophists," got a bad name in antiquity,[1] and Aristotle treats them disparagingly as mere charlatans. Thus, while Eristic is arguing for victory, he describes Sophistry as arguing for gain. The Sophist, according to Aristotle, tried to refute by means of fallacy, in order that he might be thought clever, and so get pupils and make money. Aristotle collects, classifies, and exposes these fallacious refutations; and so exhaustive is he in one short book, that the human mind has hardly invented any fallacious argument since which may not be brought under some head of the *Sophistical Refutations.* The theory of fallacy was a proper wind up to the *Organon*, as containing the theory of reasoning in all its branches. Aristotle concludes this part of his system with words full of a just pride in his achievements. It is almost[2] the only place in his writings in which any reference to his own personality can be traced. He says,[3] "In regard to the process of syllogising I found positively nothing said before me; I had to work it out for myself by long and laborious research."

Greece at this time was full of Dialectic and Rhetoric, and the two were closely connected; and it was quite natural for Aristotle (whose aim was to take up and carry out to perfection all that the intellect of his countrymen had assayed), next in order after Logic and Dialectic, to deal with Rhetoric. We have already seen (p. 515) that he probably wrote his *Rhetoric* immediately after the main books of the *Organon*, but before the *Sophistical Refutations.* But a distinction must here be added, for it seems pretty plain that, after he had written the two first books of his *Rhetoric*, there was an interval, and that he did not add on the third book[4] for some time afterwards. Many treatises on the same subject had previously been composed, an account of which has been given by Spengel in his *Artium Scriptores*,[5] or *Writers of Arts of Rhetoric*, a work professing to replace, as far as might be, the lost book called Συναγωγὴ τεχνῶν, attributed, rightly or wrongly, to Aristotle. It is a curious fact that one of these earlier systems of Rhetoric has been preserved for us among the works of Aristotle, having been long attributed to him on account of a spurious letter prefixed to it, and purporting to be from Aristotle to his former pupil, Alexander the Great. Hence the treatise got its name of *Rhetoric, addressed to Alexander.* But the investigations of scholars[6] show conclusively that this work could not have been written by Aristotle, that with great probability it may be attributed to Anaximenes, the historian and rhetorician, and that it was written between 340 and 330 B.C., only a few years before the composition of Aristotle's treatise. The work itself is representative of the school of the Sophistical Rhetoricians, and abounds in those tricks of procedure[7] which gained their bad name for the Sophists, and which drew forth the reprobation both of Plato and Aristotle. Plato,[8] indeed, identified rhetoric with trickery, and refused to countenance the study of it. Aristotle, who often exhibits less moral earnestness, but greater intellectual breadth than Plato, thought it necessary that this, like other intellectual fields, should be exploited. He thought,[9] amongst other reasons, that unless this were done, truth and justice would sometimes be left deprived of proper representation and support. He repudiates the practice of the earlier rhetoricians, who had based their "Arts" entirely on appeals to the passions; and in a large and manly way he proceeds to develop all the various points which an orator must keep in view, and to indicate all the kinds of knowledge which he must acquire in order to be master of his profession. In so doing, Aristotle has displayed his extraordinary power of exhausting any subject to which he gave his mind. Hardly anything of importance on the subject of Rhetoric has been added to what he wrote. Take the most powerful and subtle specimens of modern oratory,—for instance, Shakspeare's speech of Mark Antony over the body of Cæsar,—and you will find the *rationale* of every telling point set forth by anticipation in the *Rhetoric* of Aristotle. His work contains some few Greek technicalities,—for instance, the doctrine of the Enthymeme,[10] or rhetorical syllogism,—on the precise nature of which commentators are not agreed. But the main bulk of the treatise consists of a rich collection of remarks on human nature and life, applicable to all periods. In the wisdom and knowledge of the world which it exhibits, Aristotle's *Rhetoric* might be compared with the *Essays* of Lord Bacon. And it might be compared with them also in this respect, that a bad and Machiavelian use might certainly be made of some of the suggestions which it contains, though Aristotle professes only to give them to be employed in the interest of truth and justice. The third book, on Style, is excellent so far as it goes, but it is less exhaustive and universally applicable than the former books, which treat of the matter of speeches.

Rhetoric was said by Aristotle[11] to be allied, on the one hand to Dialectic, on the other hand to Ethics; and, accordingly, he seems to have gone next to the exploration of the latter subject. At all events he wrote the *Nicomachean Ethics* later than the *Rhetoric.* When we compare the two treatises together we are struck with the growth of mind which has taken place between them. The *Rhetoric* is full of ethical definitions of happiness, pleasure, virtue, friendship, and the like. But in the *Ethics* these are all remodelled, and made far deeper and more exact.

The *Nicomachean Ethics* was, perhaps, the first of Aristotle's extant works which entered upon the matter of knowledge, as distinct from the theory of the reasonings by which knowledge is obtained, and from the theory of the statement by which knowledge may be best set forth. The moral system herein contained differs from the ethics of Plato, *first*, in its more accurate psychological analysis, in distinguishing the will from the intellect, and in making virtue to consist in a formed state of the will, rather than

[1] A controversy on the justice of the reproaches of Xenophon, Plato, Aristotle, &c., against the Sophists, was initiated by Grote in vol. viii. of his *History of Greece*, and continued in his subsequent works on Plato and Aristotle. On the other side, see Prof. Jowett's *Dialogues of Plato translated* (vol. iii. p. 449, *sqq.*)

[2] Another exception is in *Eth. Nic.* i. 6, where he refers to the fact of Plato having been his friend.

[3] Mr Poste, in his *Aristotle on Fallacies*, p. 95, translates the words, περὶ τοῦ συλλογίζεσθαι, as if they meant "on dialectic" generally. But the general opinion is, that Aristotle was here referring to his having worked out the forms of the syllogism.

[4] Book iii. opens with the same words with which book ii. had concluded. This looks as if Aristotle had returned to the subject after an interval, having forgotten the exact form of what he had before written. This book (c. i. § 10) quotes the treatise *On Poetry*, which must have been written in the meantime.

[10] The Enthymeme is a rhetorical (*i.e.*, non-demonstrative) syllogism. Its premisses are "signs" and "probabilities." Its province is to show likelihood, not certainty. The question with scholars is, whether it is essential to the Enthymeme that one of its premisses should be left unexpressed. See Sir W. Hamilton, *Lectures on Logic*, vol. i. p. 386, *sqq.*; Mr Cope's *Introduction*, p. 103, *sqq.*, and Grote's *Ar.*, vol. i. p. 291, *sqq.*

[11] *Rhet.*, i. 2, 7.

in wise insight; *secondly*, in being disconnected from any assumption, or theory, of the immortality of the soul,—from all that we should call "Faith." Whether or not Aristotle denied a future life is another question to be considered later. But at all events he constructed ethics independently of such a doctrine. On the other hand, his system differs from the modern point of view, in that he asks, not, What is right? what is our duty? or what is the ground of moral obligation? but, What is the chief good for man? In order to answer this question, he calls in the aid of his metaphysical forms of thought,[1] such as the doctrine of the Four Causes, and of Actuality and Potentiality. From these he deduces that the chief good for man must consist in something which is an End in itself, and that it must be found in the actuality of the human powers. It is a weak point in the system that, instead of at once recognising the law of moral obligation as the deepest thing in man, it introduces[2] the idea of virtue and morality in a dry logical way, saying that the chief good for man must be the actuality of his powers according to their own proper law of excellence (κατὰ τὴν οἰκείαν ἀρετήν). Having in this colourless and neutral way brought in the term ἀρετή = excellence or virtue, Aristotle divides it, in relation to man, into moral and intellectual. The part of his work which treated of intellectual excellence is lost, or was left unwritten. His discussion on moral excellence or virtue is full of interest. Its salient points are—*first*, the doctrine of the formation of habits or states of mind; *second*, the doctrine of "the mean," as the essential determinator of virtue; *third*, a brilliant analysis of the qualities and characters which were reckoned either as cardinal or secondary virtues in Greece. On Aristotle's doctrine of "the mean" a word must be said. Objection has been made to it in modern times, on the ground that it sets up a merely quantitative difference between virtue and vice. But Aristotle's point of view was thoroughly Greek, it was based on the analogy of Art. When we speak of actions being "right" or "wrong" the Greeks spoke of them as being "beautiful" (καλά) or "ugly" (αἰσχρά). In all Greek art and literature the great aim was to avoid the "too much" and the "too little," and in this way to attain perfection. Aristotle only followed Greek feeling, and the lead of Plato,[3] in applying the same idea to morals. It might, indeed, be urged that this idea of "the mean," of "neither too much nor too little," is a negative and merely regulative conception, and that it does not suffice to explain the moral beauty of the phenomena which Aristotle had in view. For instance, he describes the brave man[4] consciously meeting death for a worthy object, and consciously sacrificing life and happiness, and much that he holds dear, because he feels that it is "beautiful" to do so. But, so far as we can learn from Aristotle, the "beauty" here consists in exhibiting neither too much nor too little boldness, but the exact mean. In this there is obviously something inadequate; but the fault seems to lie, not so much in laying down "the mean" as the law of beauty, but rather in not going beyond the identification of the morally admirable with the beautiful. This leaves each moral action, or course of conduct, to be judged of as a work of art. The proportions in each case are relative, but he who can judge aright will feel the harmony or otherwise of the details. With this artistic and somewhat superficial conception of morality, Aristotle is, in his own way, an intuitionist. He thinks[5] that we have a sense (αἴσθησις) for moral beauty, but that this sense exists in perfection in the wise man (φρόνιμος), to whom in all cases must be the ultimate appeal.

But the whole question of man's moral nature is really subsidiary in the *Ethics* of Aristotle. His question is, What is the chief good for man? and the answer to this question is, It must consist in the evocation and actuality of man's highest faculty, namely, the Reason. Thus, the highest happiness is to be found in contemplation and speculative thought; the joys of the philosopher are beyond compare. A satisfaction of an inferior kind is to be found in the exercise of the moral virtues. Such is, in brief, the view which Aristotle gives of human life. He excludes religion from his consideration of the subject, though his disciple, Eudemus,[6] in restating his conclusions, tries to introduce it. The same question, What is the *summum bonum* for man? has been answered in somewhat similar terms, in modern times, by Spinoza.[7]

The concluding paragraphs of the *Nicomachean Ethics* form the prelude and introduction to the *Politics* of Aristotle. Neither virtue nor happiness,[8] he says, can be attained by the individual separately. Moral development and the realisation of our powers (ἐνέργεια) require as external conditions a settled community, social habits, the restraint and protection of laws, and a wisely-regulated system of public education. Man is by nature a political creature; he cannot isolate himself without becoming either less or more than man (ἢ θηρίον ἢ θεός). Thus the state is a prime necessity to man, and, indeed, the state is prior in idea to the individual, that is to say, the normal conception of man is of man in a state of civilisation, and this implies beforehand the conception of a state. On these grounds Aristotle went on from his *Ethics* to the composition of his *Politics*. Some little time,[9] however, may have elapsed between the two works. This is suggested by the mature and free handling given to ethical questions when they occur in the *Politics*. Aristotle, with his usual tendency to seek a solid basis of experiences for his theories, may, in this interval, have been engaged in making that remarkable collection called the *Constitutions* (Πολιτεῖαι), which, according to Diogenes Laertius (v. 27), contained a description and history of the constitutions, manners, and usages of 158 states, and of which numerous fragments[10] remain. However this may be, the *Politics*, as we possess them, are full of learning and information. After a preliminary dissertation on the family as a unit in the state, they give a critical history of previous philosophical theories of politics, and an examination of some of the chief existing constitutional systems, before proceeding to the statement of Aristotle's own view. The treatise is unfinished; in Bekker's edition it breaks off in the middle of Aristotle's theory of education (book viii.) Some have thought that this unfinished book was put last by some editor because it was unfinished, but that it originally stood earlier in the treatise, and that the commonly received order of the books should be transposed as follows:—i. ii. iii. vii. viii. iv. vi. v. It is forcibly argued[11] that a better

[9] Spengel thinks that "the *Politics* were written long after the *Ethics*."

[10] These, as collected and annotated by C. F. Neumann, are given in Bekker's Oxford edition of Aristotle.

[11] See M. Barthélemy St Hilaire's *Politique d'Aristotle* (Paris, 1837); Spengel, "Ueber die Pol. des Ar." (*Abhand. der Bayerisch. Akad.*, 1849); Nickes, *De Arist. Polit. Lib.* (Bonn, 1851); and Mr Congreve's *Pol. of Ar.* (London, 1855, 1874).

logical order for the subject matter of the entire treatise is thus provided; book i. being preliminary on the family, book ii. being critical of previous theories and existing constitutions, books iii. vii. viii. giving Aristotle's own conception of an ideal state (unfortunately not concluded in the most interesting part of all), books iv. vi. v. forming a return from the ideal point of view to practical statesmanship, and suggesting remedies for the different evils apparent in the actual Governments of Greece. Suffice it, however, to say that the *Politics* of Aristotle have come down to us in a fragmentary condition, not carrying out all that their author had intended, and probably never having received his last hand. The contents of this work are interesting, *first*, from an antiquarian point of view, as throwing a flood of light on Grecian history; *secondly*, from the knowledge of human nature and the wise remarks applicable to all times with which they abound. On the other hand, Aristotle's considerations are too much confined to Greek states, that is, to states on an extremely small scale, to allow of his political theories being very useful in modern times. Owing to this his *Politics* have been comparatively little studied. It is said[1] that in the Italian republics, from their resemblance to the Greek states, more attention than elsewhere was paid to this treatise. Aristotle had no political ties; he lived at Athens as a *metic*, or foreigner, without the rights or duties of a citizen, and thus he was in a position to write, with the utmost impartiality, of political questions. But his statesmanship does not appear to have extended to what we should call the "balance of power," by which national existence might be preserved and guaranteed. He limited his view to the well-being of each little state within itself, though he probably would not have objected to, and perhaps even contemplated, the hegemony of Macedonia, provided that under this each Greek city were left to carry on its own civic life.

His ideal state contrasts favourably, from a scientific point of view, with that of Plato. For while giving, as we have seen above, great and predominant weight to the idea of the state, he refuses to allow the individual and the family to be absorbed by the state. He thus resists all approaches to that communism[2] which was carried to so great extravagance in the *Republic* of Plato. The form of government which, ideally speaking, he prefers, is a wise monarchy or aristocracy,—some government, in short, in which neither wealth nor numbers shall be permitted to determine everything. In some points it must be confessed that he exhibits a narrow and conservative spirit, and a belief in the divine right of things as they are, which puts him at a disadvantage in comparison either with Plato or with modern views. Thus, despite counter opinions in his own day, he maintains the institution of slavery as based on nature, and even lays it down[3] that it is justifiable to make war upon and reduce to slavery those races who were evidently intended by nature to be subject. In accordance with his physiological system, he treats woman[4] as stunted man, fixed by nature in a position of inferiority; and, therefore, he resists Plato's proposals for the emancipation and improved education of women. And by a third misapplication of his favourite conception of "nature," he denounces interest[5] as unnatural, money being a mere instrument of exchange, whereas interest unnaturally increases it. These specimens of backwardness of thought all occur in the first book of the *Politics*, and may serve to show how much "Truth is the daughter of Time," and into what weaknesses the strongest individual minds may fall on questions not yet sufficiently ventilated and sifted by time. From his unfinished theory of education[6] in the eighth book of the *Politics*, Aristotle was led on to the composition of his work *On Poetry*. This also is a fragment, and while promising[7] to treat of tragedy, comedy, and epic poetry, it treats only of tragedy, adding a few brief remarks on epic poetry, and omitting comedy altogether. Aristotle, when he wrote it, had not yet written the third book of his *Rhetoric*,[8] and he had not yet got the division of the two subjects clear in his mind; for he introduces into his fragment *On Poetry* observations on style, and even on grammar, which would have been more appropriate elsewhere.

His account of tragedy is a profound piece of æsthetic philosophy. By implication he defends tragedy against Plato, who had wished to banish the drama from his ideal republic, as tending to make men unmanly. In his celebrated definition of tragedy,[9] Aristotle says that, "by pity and fear, it effects the purification of such feelings." On the exact meaning of these terms a lively discussion[10] has taken place in Germany. The question is, whether "purification" (κάθαρσις) has a moral significance, such as was associated with the term in the Greek "mysteries," or whether it is a purely medical metaphor, and means simply "purging." In the *Politics* (viii. 7, 3) Aristotle has used the same term (κάθαρσις) in reference to the effect of certain kinds of music, and had promised to give a fuller explanation of it in his treatise *On Poetry*; but this promise is unfulfilled, and we have rather to go back to the *Politics*[11] as affording most light on the subject. The result of the discussion seems to be that κάθαρσις is a medical term, and that Aristotle's meaning is that tragedy, by causing the feelings of pity and fear to "operate" pleasurably, relieves[12] the moral nature of a certain burden. We must regret, however, that the fuller disquisition on this subject, which he had promised, has not been given. Much stress has been laid, especially by the French, on "the unities" of the drama, as supposed to be prescribed by Aristotle *On Poetry*. But in reality he attaches no importance to the external "unities" of time and place. In enumerating the differences between tragedy and epic poetry, he says,[13] that "the one generally tries to limit its action to a period of twenty-four hours, or not much to exceed that, while the other is unlimited in point of time." But he does not lay this down as a law for tragedy. The peculiarity of the Greek drama, in which a chorus remained constantly present and the curtain never fell, almost necessitated "the unities," but Aristotle only concerns himself with internal unity, which he says that tragedy must have in common with every other work of art,[14] and which consists in making every part bear an organic relation to the whole, so that no part could be altered or omitted without the whole suffering. This principle, much more valuable than that of "the unities," is habitually

violated by all but the few first-rate works of fiction of the present day.

The *Rhetoric*, the *Nicomachean Ethics*, the *Politics*, and the fragment *On Poetry*, make up the sum of Aristotle's extant contributions to "practical" and "productive" philosophy. We have now to follow him into the "speculative" part of his system, consisting of a rich series of physical and physiological treatises. In this department the results arrived at 2200 years ago by Aristotle come into sharp contrast with the achievements of modern science up to the present day. Those who enter upon the comparison are apt to run into one of two extremes,[1]—either to pass undiscriminating eulogies on Aristotle, and to credit him with impossible anticipations of future discovery, or to treat him with undue disparagement, as utterly false in method and puerile in his views of nature. It is only owing to Aristotle's real greatness that such a comparison could for a moment be made,—for what, comparatively speaking, could be expected of a philosophy 2000 years old in respect of the sciences of observation and experiment, whose very essence consists in gradual advance from one new vantage point to another? To do personal justice to Aristotle, we must conceive, as a matter of fancy, what it would have been if he could have had one of the great modern discoveries imparted to him,—the Copernican system, or the law of gravitation, the circulation of the blood, or the analyses of air and water, or the conservation of energy; if he could have had any modern instrument of observation, such as the telescope or microscope, or even the thermometer or barometer, placed in his hands. How swiftly would he have used such an advantage! what new and ramifying deductions and inductions he would have made! how radically he would have had modified many of his views! But all this was, of course, impossible. Physical knowledge was in its infancy; Aristotle could only start where his predecessors left off; he laid the foundation of many sciences, and wherever simple observation was adequate,—as, for instance, in politics and in some parts of natural history,—his achievements were complete and surprising. But for the greater realms of science he had no starting point and no appliances; he could only slightly modify the almost childlike views of the Greeks, and rest content with such unverified hypotheses[2] as seemed to him best to cohere together, and to explain the nature of things. Thus, it is not to be wondered at that he considered the earth to be stationary and the centre of the world, with the seven planets (including as such the sun and moon) moving round it in oblique courses to the left, while the outer heaven or sphere of the stars—composed not of perishable matter, but of divine ether—he thought to move from left to right, with perfect and regular motion returning on itself, deriving its motion from the encompassing Godhead,—that essence which moves things, but is not moved itself. Such was, according to the belief of Aristotle, the framework of the universe; and the order[3] of his physical treatises corresponds with the filling up of this framework. Of his method it may be said, in one word, that no one was ever more keen than he to make "fact" (τὸ ὅτι) the basis of every theory. It is not to be supposed for a moment that he attempted to explain nature by means of the syllogism. But, on the other hand, the art of experimenting, and the exact quantitative record of observations had not been developed. So Aristotle was often quite destitute of the appropriate "facts" for a particular inquiry, and sometimes deceived in the "facts" upon which he founded. And his training as a dialectician was in some respects a disadvantage to him, as it led him to depend too much on the evidence of language in forming his theories of nature.

The logical order of the physical treatises, and, probably to a great extent, the actual order of their composition, is as follows:—1*st*, The *Physical Discourse*, in eight books, forms an introduction to the entire subject. It is, as Hegel called it, "a Metaphysic of Physic." It treats of the Principles of Existence, Matter and Form, Nature, Motion, Time, Space, the Unmoved First Mover, and the Ever-moved, *i.e.*, the sphere of the outer heaven. 2*d*, The treatise *On the Heavens*, in four books, naturally succeeds; and Aristotle, thus beginning with the periphery and divinest part of the universe, descends gradually to the region of the material and perishable. In so doing it becomes necessary to him to consider the causes of those changes,—that passing into and out of existence,—which had no place in the higher region. Therefore, 3*d*, the treatise *On Generation and Destruction*, in two books, gives us Aristotle's theory of the Hot and the Cold, and the Wet and the Dry,—pairs of opposites, the first pair active, and the second pair passive, which by their combinations and mutual workings produce the four elements (Hot and Dry = Fire, Hot and Wet = Air, Cold and Dry = Earth, Cold and Wet = Water), and form the ground for all natural changes. 4*th*, The *Meteorologics*, in three books, treat of the region of the planets, comets, and meteors,—a region ever full of change and alteration. The fourth book of this treatise does not logically belong to it, for in it Aristotle develops his theory of two exhalations—the steamy or wet, and the smoky or dry—which, being imprisoned within the earth, produce, the former the metals, and the latter the rocks, and such other minerals as are incapable of being melted. This theory, which seems to be a dim foreshadowing of the doctrine of crystallisation, takes us out of the mid-air below the surface of the earth. It is, therefore, out of place; but almost everything in Aristotle must be looked upon as unfinished. 5*th*, The treatise *On the Parts of Animals*, in four books, leads the way to the investigation of organic life. It contains Aristotle's physiological distinction between homogeneous and unhomogeneous substances (ὁμοιομερῆ and ἀνομοιομερῆ), *i.e.*, tissues and organs. This distinction, which is recognised still as perfectly valid, gives a scale of ascension from the inorganic to the organic world. First, Heat and Cold, &c., form the simple elements; out of the elements are formed the homogeneous substances or tissues; out of these are formed the organs, out of the organs the organised being. As a principle of method, Aristotle lays it down[4] that all which is common to the various species of living beings should be discussed before entering upon their specific differences. Therefore, 6*th*, the treatise *On Soul* follows next in order, which, as Spengel observes (see note 3), is not to be regarded as a work on psychology in the modern sense, but as a physiological treatise on the soul or vital principle common to all living beings. And next follow, 7*th*, the so-called *Parva Naturalia*, which form appendices to the three books *On Soul*, and treat physiologically of sense and sensation, youth and age, sleep and waking, and other phenomena attaching to life in general. 8*th*, The short essay *On Locomotion of Animals* shows how various organs in the

[1] This subject may be studied in Mr Lewes's *Aristotle, a Chapter from the History of Science*, referred to in note 5, p. 511. Mr Lewes quotes some of the principal eulogies upon Aristotle's scientific merits. He himself affords an instance of the opposite extreme, being in many points too hard upon Aristotle.

[2] There are some interesting remarks on the position of a Greek philosopher of the 4th century B.C. in relation to physical science, in Professor Jowett's *Dialogues of Plato, translated* (Oxford, 1871), vol. ii. p. 503, *sqq.* in the introduction to the "Timæus."

[3] See Dr Leonhard Spengel's paper on this subject, *Abhandlungen der Philos.-philol. Klasse der Bayerischen Akademie*, 5th vol. 2d div. p. 142 (Munich, 1849).

[4] *De Part. Anim.*, i. 1, 4-7.

various creatures are adapted by nature for this purpose. 9*th*, The elaborate treatise, in five books, *On Generation of Animals*, works out this subject with astonishing fulness. And, 10*th*, the great work entitled *Researches about Animals*, in ten books, in which Aristotle exhibits an acquaintance, more or less intimate, with about 500 species,[1] crowns the series of his physical writings, and certainly constitutes one of his greatest achievements.

There were two other treatises which Aristotle had proposed[2] to himself to write, as belonging to this πραγματεία, or department, namely, one *On the Physiology of Plants*, and one *On Disease and Health, so far as belongs to Physical Philosophy*. But neither of these intentions, so far as we know, was executed by him.

Last of Aristotle's extant and undoubted works, we have to deal with the *Metaphysics*. We cannot accept the opinion expressed by Valentine Rose[3] that this work was written before the *Physical Discourse* and the other kindred books which have just been enumerated. Doubtless many of the metaphysical conceptions were pretty complete in Aristotle's head before he wrote on physics, but that is another question. The very name "Metaphysics" (see before, note 8, p. 514) embodies a strong tradition that the work to which it has been applied came "after the physical works." Secondly, There is another tradition[4] that this treatise was sent to Eudemus for revision, and that while Eudemus was suggesting some improvements in the arrangement, Aristotle died. Thirdly, there are four places[5] in the physical writings which put off the discussion of certain questions as belonging to "first philosophy," just as in the *Ethics*[6] other questions are put off as belonging to physics. Fourthly, The *Metaphysics* are quoted in no genuine work of Aristotle's, but only in the book *On the Motion of Animals*,[7] now generally attributed to a later Peripatetic. Fifthly, The doctrine of causes seems to be handled in a more mature way in the *Metaphysics* than in the physical writings. Sixthly, In no less than twelve places[8] of the *Metaphysics* the physical treatises appear to be referred to. There is good ground, then, both external and internal, for believing that the *Metaphysics* were among the latest of Aristotle's works, and they were certainly not finished by him.

As the work stands in Bekker's edition, it consists of thirteen books, exclusive of the brief fragment which succeeds book i., and is marked as A ΕΛΑΤΤΟΝ, or I. Minor. This fragment was attributed by ancient[9] tradition to Pasides, and is probably un-Aristotelian. It merely contains some very general remarks on the search for principles. Book iv. is a sort of glossary of the various meanings in which certain philosophical (but not exclusively metaphysical) words are used. It may have been jotted down by Aristotle himself, and have been found among his papers; but it is only through injudicious editing that it can hove been inserted in this work. Book x. is quite peculiar; the first half of it (chapters 1–7) is a brief restatement (by Aristotle himself, as Bonitz thinks) of the conclusions of books ii. iii. v.; the second half is an un-Aristotelian epitome of part of the *Physical Discourse*. Even making these deductions, the remainder of the work is not homogeneous, but is resolvable into two separate treatises: the first being intended to set forth Aristotle's system of metaphysic, and consisting of books i. ii. iii. v. vi. vii. viii., which give the history of former systems and the groundwork of his own. The second treatise is contained in book xi., which, after a short sketch of the nature of substance in general, ends in a dissertation upon the nature of God. Books ix. (on Unity) and xii. xiii. (on the Pythagorean and Platonic systems of numbers and ideas), appear to have been intended for the first treatise, but they remain as mere materials for a *magnum opus* which was never achieved. We see, then, out of what *disjecta membra* the *Metaphysics* of Aristotle, as they stand in our editions, are composed. How far the making up of them into their present form is due to Eudemus and the earlier Peripatetics, how far to the editorial hand of Andronicus, we cannot tell.

Among the many-sided merits of Aristotle must be mentioned the example set by him of making the history of opinion on each subject the prelude to a scientific consideration of the subject itelf. In the first book of his *Metaphysics* he sketches the leading doctrines of his predecessors on the first principles of existence. He thus becomes the father of the history of philosophy, a study which has been taken up anew and much developed during the present century. His brief and masterly sketch is, however, open to the charge of not doing sufficient justice to the different points of view of former philosophers. And his polemic against Plato's doctrine of Ideas, which is several times repeated[10] in his extant writings, has the appearance of captiousness, and of misrepresenting the[11] doctrine which it impugns. Aristotle himself never discarded idealism. He declared that universals, and the truths apprehensible by the highest reason, were "by nature more known"[12] than individual concrete phenomena, and the facts apprehended by sense. But yet he had the strongest bias towards physical research and empirical observation. A modern physical philosopher might have been content to follow out his own special inquiries without seeking a general scheme for the universe. But Aristotle had to form a theory of the whole, leaving scope, afterwards, for the separate physical sciences. The idealism of Plato did not do this: it left no place for matter, motion, or change; when followed out it reduced all but the Ideas to the category of the non-existent. Aristotle, to rescue all nature from theoretical annihilation, introduced a term between the existent and the non-existent, namely, the "potential" (δύναμις). On the one hand, the potential does not exist, for as yet it has no qualities; on the other hand, it does exist, for some change brings the "actual"
